PREFACE.

—:—

APOLOGIES for putting forth new books are not so fashionable now as in years gone by, although there probably never was a time when they might have been more reasonably expected than at present. For have we not a plethora of books on almost every conceivable subject?—and especially on foods, drinks, and other domestic accessories?

Numerous treatises have appeared on Tea, Coffee, Bread, Sugar, Oils, Fruits, Confectionery, &c.; we have Cyclopædias, Encyclopædias, Dictionaries, and such like, in ponderous tomes without number; trade journals, weekly and monthly, also abound, representative of every branch of business, and running up to hundreds of volumes! That most excellent London weekly, *The Grocer* (no relation or connection of the present Manual be it understood), has alone issued some *seventy* large half-yearly volumes, and deals most ably and exhaustively with well-nigh every interesting feature in the grocery trade as it crops up. Besides these we have shoals of Consular Reports, Magazine Articles, Booklets, and miscellaneous literature, constantly furnishing interesting details about British and Foreign commodities of all sorts.

It is, however, from this very multiplicity of books and other publications that the main trouble arises, for their great number, bulk, and costliness far exceed the resources of any ordinary shopkeeper; hence, for these reasons, coupled with want of time and opportunity, the knowledge they contain is practically inaccessible to the majority of retailers, shop assistants, apprentices, &c., especially when these persons are located in our smaller towns and villages. It may also be asserted that in no single book hitherto published will the grocer find any mention of half the articles he handles, while the facts he wants are generally so mixed up with matter he does *not* want, as to render any investigation very tedious and discouraging if not absolutely futile. Trades also so overlap each other, and colloquial terms applied to one and the same article in different districts are so numerous, that there is frequently much confusion; but the registration of

Trade Marks, Brands, and fancy names, such as *Albany Food, Bovril, Clarnicol, Cocoagene, Coraline, Cybil, Cytos, Easteleine, Eglah, Hovis, Izal, Kassama, Kleenitself, Komo, Lohsine, Malasso, Marol, Manhu, Mortadello, Oxyron, Ptyaloid, Pynka, Rubytine, Tripoline, Urbose, Vigoral, Viko, Virol, Vimos,* &c., has called forth so many meaningless titles that trade nomenclature threatens to become in the near future a positive VOLAPUK!

The Grocery trade is a very ancient one. History tells us that in the time of Edward III. a grocer was "a merchant who *engrossed* all vendable merchandise," certainly a more sweeping interpretation than the most enterprising storekeeper of to-day will lay claim to. But it is doubtful whether the vendable merchandise of that period numbered a tithe of the commodities which now swell the stock of a modern retailer. A multifarious array of household accessories and luxuries never dreamt of then, is constantly increasing, and like Tennyson's brook seems likely to "go on for ever!" Such are the considerations which suggested the following pages. It occurred to the compiler that without assuming any particular literary ability, his forty years' London and provincial connection with the trades referred to might enable him to sort out, classify, and bring into a single volume the most useful details as to the source, nature, history, composition, preparation, and exploitation of the raw products, manufactured and proprietary articles, trade appliances, &c., common to grocers, provision dealers, chandlers, fruiterers, bakers, confectioners, and general-shop keepers.

The incorporation of some hundreds of recipes likely to be of service, hints on business management and shopwork, along with tables, calculations, and other collateral information, have all helped to make up a book which, in the absence of any other work of the same sort, may be found in some degree worthy of its title. Its compilation has formed an agreeable occupation for three or four evenings weekly during the last half-dozen years. Perhaps it may be said that comparatively few shopkeepers ever trouble their heads about what things are made of, or where they come from; but such indifference will never pay, and is manifestly adverse to the best interests of both masters and men. The off-hand argument that "*our business is to sell and sell only*" cannot be altogether satisfactory to those who reflect that the recently invented Automatic machines may soon beat them at that! Possibly it is under such notions as the above that customers are so often served mechanically, without any thought or heed as to whether they may or not care to visit that shop again. But a trite old adage says:—"*Learn but little and work but little, and you may remain a drudge for ever.*"

Nothing attracts the interest of the consumer more than learning how an article is prepared; and the man who aspires to be something more than a mere shop machine, who determines to learn the most he can about his own trade, and thus be prepared to give intelligent and ready answers *when asked* as to the nature, composition, or origin of the goods he sells, will not only win the respect and confidence of both customers and employers, but will also be best qualified to select his own stock, so as to make the most profit and avoid the most losses.

Everything on earth is perishable, but most of the articles dealt in by the trades here referred to are peculiarly so, and often deteriorate very quickly, while very few improve by long keeping. Some are apt to ferment, lose flavour, colour, or other virtue, and so become stale and useless, others get soiled and spoilt for sale from improper treatment in handling or storage. It is no exaggeration to assert that many thousands of pounds worth of goods are lost or wasted yearly in retail shops from ignorant or careless management and other preventable causes within the art of efficient traders or assistants to avert, or at least to minimise to a fraction by combining a little original thought with a wide gleaning of known facts.

The system of packeting goods in small parcels with spicy titles, which has been coming more and more into vogue since 1856, when wholesale firms began grinding, has operated very unfortunately on the retailer. Not only has it undermined the probability of his ever obtaining any "goodwill" for a business to which he may have devoted the labours of a lifetime, but in conjunction with an ill-considered Adulteration Act it has exposed him to other costly perils, such as—(1) the cupidity of unscrupulous importers, manufacturers, and wholesale dealers; (2) the traps and trickeries of scheming inspectors; (3) the errors and quibbles of incompetent analysts; and (4) the idiosyncrasies or prejudices of different magistrates. It is notoriously a scandal to justice and legislature alike that there is scarcely a grocer in the country who has not been mulcted in fines or other expenses, and held up to ignominy through no fault of his own! Penalties for adulteration should admittedly be inflicted on guilty parties, but anyone at all acquainted with the inner workings of a retail concern knows that there is practically no adulteration there, nor indeed anywhere else on the *retailer's* behalf.

The old crusted stories about wooden nutmegs, turnip preserves, sanded sugar, hawthorn-leaf tea, &c., are probably too amusing ever to die out; but if glucose be, as no doubt it often is, substituted for sugar in honey, marmalades, &c.; rotten figs for jam; exhausted spices for genuine; ground walnut shells for cinnamon; powdered olive stones or fine earth for ground pepper; pellets of clay or coloured farina for peppercorns, coffee berries, &c.; perfumed glue or paraffin wax at 2d. per lb. for gum at 1s. per lb., and so forth; everyone, even magistrates should know perfectly well that it is not the retail shopkeeper who is the guilty counterfeiter, but the manufacturers with extensive plant, the importers or the wholesalers, who deal in hundredweights and tons, and among the more unscrupulous of which there is constant emulation as to who can discover, employ, and keep secret the cheapest substitute for any honest and wholesome ingredient hitherto used. The fabrication of the more costly products by *synthesis* has doubtless been found highly lucrative! Tests have, of course, been discovered by which many forms of adulteration may be determined with reasonable certainty, and most of these have been noted in this book; but unfortunately, sophisticators are no less expert and active. No sooner is a valuable test discovered than some way is found to circumvent it. Each firm knows remarkably well what it is selling and sending out, but the busy retailer is too frequently left in the dark as to what he is buying. He innocently sells it as received, trusting all is well, and only discovers the facts when hauled before the magistrates, ruthlessly fined, and often ruined!

Many Guides, Handbooks, Brochures, Pamphlets, &c., have been published under the auspices of manufacturers or others similarly interested; but, like quack advertisements, are generally unreliable, and only intended to make known the wonderful virtues of their own goods. Very rarely is any clear insight offered as to the composition or method of manufacture. Consumers are only expected to shut their eyes and open their mouth. Their is also a growing passion for anonymity not always due to excessive modesty. The labels on the goods, often without name and address, are frequently silent as to the real nature of the contents, or remarkably indefinite; while others are studiously misleading, if not absolutely fictitious both as to names and contents.

Of course the exact proportions of the various constituents can scarcely be expected, these secrets being fairly the property of the individual firms; but such general approximations as are common knowledge with each class of manufacturers should certainly not be withheld from the retailers.

Shopkeepers, like others, are also often misled by the letters of professional testimonial writers, analytical reports, exhibition medals, Royal patronage, &c., which are of doubtful value. The particular samples, even if competently examined and reported upon honestly, may have been specially prepared for the occasion, or may not even have been manufactured at all by the parties to whom they are attributed; and in very few cases is any certain proof offered that subsequent outputs approach the same standard.

In conclusion it may be that some of the articles described in the following pages are almost outside the trades named, but the contrast between the stock of a City Establishment and the ramifications of a Village Shop is very great, and, although both may claim to be "grocers," it might be difficult to decide which is the more orthodox.

An attempt has been made to give the names and addresses of a few special firms, which are not perhaps so widely known among retailers as they should be.

The Supplementary Index near the end of the book will be found useful in pointing to a few matters which have no distinctive heading; extra cross references being given wherever likely to prove useful.

All blame for errors, faulty composition, &c., must be laid to the compiler, and any praise must be credited to the various authorities from which the information has been gathered. The chief of these are enumerated on pages 18 and 19.

Much valuable help has been received from trade friends, commercial gentlemen, manufacturers, and others, to each of whom my sincere thanks are due, and are hereby cordially extended.

The liberal patronage of several advertising friends must also be acknowledged, without whose favours a work of this magnitude could not have been published at the price.

J. T. L.

Islington, Liverpool.

PREFACE TO THIS SECOND EDITION.

This new edition of the Grocer's Manual is but an extension and revision of the first. The original design has been so widely appreciated that I have simply kept on trying to improve it by jotting down and arranging plainly and briefly as possible the matters most likely to be of permanent interest and utility to busy retailers and their assistants.

Several generous readers have also favoured me with valuable information to the same end and I feel much indebted to every one of them.

The consequence is that the contents have been almost doubled and the price of the book has had to be slightly raised.

Nevertheless, I have every confidence that it will be found a profitable investment, rather than a mere expenditure, of the hard earned shillings of any of its purchasers.

J. T. Law.

LAW'S GROCER'S MANUAL.

A

Abasas.— A second class quality of Portuguese wine, but considered light and wholesome when unadulterated.

Abbocati.— An Italian term for their sweet wines, such as Aleatico, Moscatello, Vino Santo, Vernaccia, etc., produced in the Roman States.

Abdelari.— An Egyptian fruit resembling the melon.

Abernethy Biscuits.—These do not take their name from the celebrated surgeon, but from the town of Abernethy, in Scotland.

The best are made of fine flour, milk, and a few caraway seeds.

Abernethy's Pills.—Each pill is said to contain two grains of blue pill and three grains of compound extract of colocynth.

Absinth.— F. *Absinthe;* Ger. *Wermuth;* Sp. *Ajenjo.*

Absinth or *Liqueur d'Absinthe* (pr. absant') is a strong and bitter spirituous liquor, of opaline-green colour, distilled in alcohol from the pounded leaves and flowering tops of a species of the wormwood plant, *Artemesia absinthium* and *Inula Helenium,* together with other herbs or chemicals to give the green colour and to render the taste more agreeable, such as angelica root, fennel, spinach, nettles, parsley, sweet-flag root, southern-wood, balm, caraway, star-anise, and hyssop; it is said to be coloured with turmeric, indigo, and sometimes with sulphate of copper. Absinth is tonic, stimulating, febrifuge, and vermifuge in its action, but bitterness is its principal merit; and it is primarily intended for use before meals as an aperitive.

It was originally invented and made at Couvet, in the Canton of Neufchatel, Switzerland, about 1740, and a quantity is still made there; but is now chiefly made by the same firm (Pernod & Son) in a larger establishment at Pontarlier, in France, by patent obtained from its first inventor, although there are numerous other makes, such as "*Absinthe Terminus,*" "*Absinthe Monopole,*" etc., etc., produced elsewhere, and particularly in the suburbs of Paris.

Absinth first became popular in France about 1830, as a febrifuge recommended to the soldiers during the Algerian war in the time of Louis Philippe; in Oran and Constantine fever made grievous havoc in the ranks of the army, and as the soldiers' usual drink was white wine, the doctors advised that absinth should be mixed with it as a preservative against miasmata, and in lieu of quinine, which latter was then very expensive. During the whole of the campaign the army drank this mixture, and even mixed the absinth with their brandy. Each regiment on returning to France brought with it the taste for absinth, and the habit soon became fashionable in Marseilles; then advanced and settled in Paris; it afterwards became the favourite drink of the country and of the French colonies.

Its use is now forbidden throughout the French army, although, as a fact, it is still consumed, both by officers and men, out of barracks, and it is only in the extreme north of France that absinth drinking is to any large extent eschewed. Some 2,000,000 gallons are still imported into that country, besides what is made there, and its effects are very injurious, its continued use producing a peculiar

morbid condition; indeed, its evil effects are soon apparent, utterly deranging the digestive system, weakening the frame, and, if persisted in, extreme nervousness, horrible dreams, and hallucinations follow, often ending in paralysis and death.

Some even attribute the French disasters in the German war to the indulgence of officers and men in this chronic poison.

The lamentable results of its immoderate use are, however, worst in Cayenne, New Caledonia, and Port Said, where it is drunk in excessive quantities and undiluted. In England the consumption has never been large, but it is increasing, particularly in London.

Absinth is generally sipped in water or spirits and water, the water being poured drop by drop on a piece of lump sugar held in a spoon over the glass containing the absinth. Sometimes the absinth is mixed with its own volume of *sirop de gomme*, the latter consisting of gum Arabic, sugar, and water, flavoured with orange essence. Confirmed habituees will not hesitate to drink it in iced water or in ordinary spirits and water. Its volatile oils are thrown out of solution and turn these mixtures quite white and cloudy.

The strength of most absinths is 72 per cent. of alcohol, but the cheaper kinds rarely exceed 50 per cent.

Absinthe Suisse is not made from the true absinth plant, but from other species of the same family, usually called "*Génépi*."

Abyssinian Coffee.—A kind of bastard Mocha, often called "East African," similar in appearance to the lower qualities of East Indian Plantation and Guatemala, and is generally classed as "fine ordinary" or "Long Berry Mocha." It is largely sent from Massowah to Aden, Djedda, and Alexandria for re-exportation, as the produce of Mocha. Coffee is indigenous to Abyssinia, and grows wild in many parts of that country. In fact, the whole country—mountain, valley, and plain—abounds in coffee, from the borders of Nara to the Nile, and forming the chief wood of the country. It is brought into Adis Ababba from various districts, but "Kaffa," in the south-east, whence coffee derived its name, is the most productive region. It is the parent plant of all the varieties found on the Red Sea littoral. The crop is very large, and a dollar will purchase 8lb. or 9lb. in the interior, the pound of coffee being calculated at the weight of 18 Maria Theresa dollars. Strange to say, very little coffee is consumed in Abyssinia. The berries are small, long, and narrow, hard and flinty in texture, but fairly even, with green tinge and a few pale berries, but they roast well, and give a fairly good liquor, and, though not of first-rate quality, possess a special aroma.

Abyssinian Tea.—Also known as *Kaat* or *Kat*, and obtained in Abyssinia from the dried leaves of the plant *Catha spinosa*, which are stimulant, anti-soporific, and anti-narcotic. Used by the Arabs to produce wakefulness.

Acacia Gums.—See *Arabic Gum*.

Acajou Nuts.—See *Cashew Nuts*.

Acetate of Copper.—See *Verdigris*.

Acetic Acid.—(See also *Acid Vinegar*.)—F. *Acide acetique*; Ger. *Essigsäuren*; It. and Sp. *Acido acetico*; Lat. *Acidum aceticum*.

A thin, colourless liquid like water, but with an intensely strong and sharp acid odour and sour taste, almost suffocating when placed under the nose, and with a highly inflammable vapour. It is this kind of acid which forms the basis or sourness of vinegars, and, in fact, the only ingredient of hygienic value in them. It is composed of two atoms of carbon, four of hydrogen, and two of oxygen, and when pure it is very corrosive.

The modern product is obtained from one of several sources; from wood, from acetate of soda, or from fruits, vegetables, spoilt wines, alcohol, etc.

That obtained from wood is called pyroligneous acid, wood acid, or wood spirit, and the process is technically described as "the destructive distillation of wood." For example, a pound of wood (oak or beech is best) chips, sawdust, or spent dye-wood, burnt to a red heat in a large cylinder to which a worm or condenser is attached, is quickly changed into some four ounces of charcoal and seven ounces of sour tarry liquid. This charcoal is of the best quality, and mostly used in making gunpowder, while the crude liquid is afterwards freed from methylic alcohol, oleaginous and tarry matter and its other impurities, by lime and soda, when it becomes acetate of soda. The acetate of soda is then distilled with vitriol and made into acetic acid, clear as water. This sort of acetic acid is considered the best for preserving animal and vegetable substances on account of the traces of essential oils, creosote, and other hydrocarbons which it contains, and which increase its antiseptic properties as an antiputrescent. Its value depends on its strength, freedom from tarry odour, and general purity.

Acetic acid has also long been obtained from the oxidation of fruits, spoilt wines, etc., especially on the Continent; also from malt liquors, sour ales, cider, and other fruit juices in this country; the necessary vinous fermentation being effected by the vegetable organism called the *mycoderma aceti*, the liquids merely undergoing a slow exposure to the open air at a temperature of 80° to 100° F.

In Pereira's "Materia Medica" it is stated that "the acetic acid of commerce is derived from two sources—vinegar and pyroligneous acid; the first is procured by exciting the acetous fermentation in certain liquids, the other by the distillation of wood."

Much confusion exists among traders regarding the strength of acetic acid when merely called by this name; its real value depending almost entirely on its strength or density, which vary very considerably. The commercial fluid may be tested by Twaddell's acetometer, but a more reliable method is to neutralise it by some standard caustic alkaline solution.

Strength and present prices:—

Per cent.	*Spec. Grav.*	*Per cwt.*
28 ...	1.040 ...	10/0
33 ...	1.044 ...	12/0
40 ...	1.051 ...	14/0
60 ...	1.067 ...	21/0
70 ...	1.070 ...	24/0
80 ...	1.073 ...	27/0
90 ...	1.068 ...	30/6
98/100 ...	1.0675 ...	33/6

and intermediate strengths in proportion. 85 to 100 per cent. strength is known as "glacial" (free from water), and runs from 40/- to 100/-, according to degrees of purity.

The British Pharmacopœia states that glacial acetic acid should contain nearly 99 per cent. of pure acid—$H(C_2H_3O_2)$; that liquid acetic acid should contain 33 per cent. of glacial acid, or 1 part of glacial acetic acid and 2 parts water (both by weight), as "ordinary acetic acid"; and "*diluted acetic acid*" 4.27 of real acid, neither more or less.

Much of that sold as B.P. acetic acid is not nearly either B.P. strength or B.P. purity. As a rule, it is oftener under 30 per cent. than over it.

The strongest vinegar usually contains 5 to 6 per cent. of real acid, and the weakest, say No. 16, about 3 per cent.

In many cases it is advantageous for dealers to buy a high strength of chemically pure acid, say 85 per cent., and then to dilute it with water to the exact strength required.

Pure acetic acid at 12° F. becomes a solid mass; at 118° it boils; and at 15° it is glacial or crystalline, forming colourless crystals of prismatic or tabular form.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Acetic Ether.—A compound of acetic acid and ether, with an odour like apples, obtained by distilling alcohol and oil of vitriol with acetate of potash. It is used as a flavouring for various wines.

Achia or **Achiar** (ak'-yar) — F. *Achard* or *Achar*.

An East Indian name for the pickled shoots of the young bamboo, *Bambusa arundinacea*. The tender stalks are first cut into short lengths and then split, put into spiced vinegar, and filled into earthenware jars. It is known to the English as PICKLED BAMBOO, and forms a yellow pickle not unlike cucumbers cut in long slices.

The term Achard or Achar is used in Malay and in some parts of France for other mixed pickles, containing peppers, gherkins, young melons, oranges, and citrons, corianders, etc. The bamboo shoots are often imported into Holland from the Eastern Archipelago.

Achira. — A species of the Canna plant, which has large roots, and yields a rich, starchy powder, like arrowroot.

Acids. — Of the endless number of acids in commerce, the sorts which interest grocers, etc., are :—Acetic Acid, Boracic Acid, Carbolic Acid, Citric Acid, Malic Acid, Nitric Acid, Oxalic Acid, Pyroligneous Acid, Salicylic Acid, Sulphuric Acid, Tartaric Acid; and these will be found referred to in their alphabetical order. For prices, etc., apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Acid Drops or **Acidulated Drops.**—A popular kind of boiled sugar-sweets, varying in value according to the quality of sugar employed, the amount of tartaric acid, and skill in boiling. A good quality may be made from 1 cwt. white cane sugar and 3lbs. tartaric acid, flavoured with a little essence of lemon and citron. (See *Boiled Sugars*.)

Acid Vinegar. —(See also *Vinegar, Pyroligneous Acid, etc.*)

A spurious sort of vinegar which, until these last few years, has been of large sale. It usually consists of one part of ordinary commercial acetic acid and five to ten parts of cold water mixed together, and then coloured with caramel or burnt sugar to the shade of vinegar required.

Some analysts say that such unfermented vinegar is not necessarily injurious, but merely inferior in quality; other scientific gentlemen think otherwise.

Sulphur acid is, of course, very injurious, and its use rigorously prohibited.

Dr. Ure, in his famous and ever-reliable "Dictionary of Manufacture," says :—"It is a remarkable fact that the people of this country have had their vinegar palate so depraved that they prefer the vitriolised vinegar to the pure, and that all attempts at introducing a better article into general sale have proved abortive—a fact discreditable to our nation."

Another writer says :—"I have before me the analysis of several samples of vinegar bought from the largest and best-known houses in London, which contain from 1.27 to 3.16 parts of *dry sulphuric acid* in every 1,000 parts of vinegar."

Some assert that a certain quantity of that most corrosive acid is necessary to prevent the "mothering" of the vinegar, and quote the permission granted to manufacturers by the Excise, when it was a duty-paying article, to mix sulphuric acid not exceeding .001; but it is argued that even this homœopathic dose is really not necessary for that purpose, and that the real reason is that the burnt taste of the acetic, or rather the pyroligneous acid, must be killed by the oil of vitriol. The detection of the sulphuric acid by the most unscientific is a very simple chemical experiment. Get a small test-tube from any dealer in apparatus, into which pour some of the vinegar you are about to buy; add to it a few drops of nitrate of baryta, also easily procurable, and if the liquid remains quite undisturbed and clear then, if it otherwise suits, you may safely buy and sell it as free from sulphuric acid.

It is certain that most of the pickles sold are preserved in acetic acid vinegar, it being made at only about half the cost of malt vinegar, but when sold, acid vinegar must be specially declared as such, and must not be supplied when "*malt* vinegar" or, perhaps, even

"*vinegar*" is asked for. Magistrates differ as regards the latter point.

Acidulated Kali.—See *Sherbet* and *Lemon Kali.*

Acidulous Waters.—A term denoting mineral waters which contain free acids in solution.

Acorns.—Du. *Akors;* F. *Glands;* Ger. *Eicheln;* It. *Ghiande;* Rus. *Schedudii;* Sp. *Bellotas.*

The fruit or seed of the oak tree. Pigs are particularly fond of them, and it is chiefly to acorn-feeding that Westphalian Hams and Bologna Sausages owe their celebrity.

A substitute for coffee has also been prepared from acorns.

Wholesale herbalists quote: Peeled Acorns, 9/- cwt.; Burnt, 16/6; Burnt and Powdered as Coffee, 20/-.

Acqua d'Oro.—(See also *Gold water.*)—A renowned Italian liqueur said to be the oldest of the very sweet kinds.

It was first taken from Italy into France in 1533 by Catherine de Medici, and got its name from the fact that the makers put powdered gold leaf in it.

Adam's Apples.—See *Forbidden Fruit* and *Plantains.*

Adams' *Extract* of HERBS.—See *Extracts.*

Adelantadillo.—A Spanish name for the first red wine drawn from the ripe grapes.

Adobado.—The Spanish name for *Pickled Pork.*

Adulteration.—See *Food and Drug Acts* at end of book.

Aerated Beverages.—(See also *Mineral Waters and Temperance Drinks.*)—F. *Eaux gazeuses;* Ger. *Brause Wasser, Gashaltige Wasser;* It. *Acque Gazose;* Sp. *Aguas gaseosas.*

These embrace a variety of acidulous and alkaline drinks, which have been artificially impregnated with carbonic acid gas or oxygen, and thus rendered sparkling or effervescent.

The consumption is very great in hot seasons, and particularly in hot countries. The whole host of these beverages—Soda Water, Seltzer or Selters, Lithia, Carrara, Potash, and other waters, as well as the popular Lemonades, Ginger Ales, etc.—are all made practically on the same basis—that discovered by Mr. Thomas Henry, a Manchester chemist, about a hundred years ago. The making of an aerated water which merely pops and fizzes is not a difficult matter, being merely plain water charged with carbonic acid gas; and the manufacture is often carried on by those who know little of the chemical and physical principles involved, but the production of a really high-class article is not quite so easy. Carbonic acid is first necessary, and this is made in a "generator," either from whiting or carbonate of lime, or, better still, a new and cheaper bicarbonate of soda specially made for the purpose, with the action of sulphuric acid, and then stored in a gasometer.

1 cwt. of whiting, 36 gallons of water, and 6¼ gallons (1cwt.) of sulphuric acid make a fair gas, but it has an offensive smell and yields a muddy deposit (calcium sulphate); while 1 cwt. bicarbonate of soda, with 18 and 19 gallons of water and 3¾ gallons (68lb.) sulphuric acid, of 167 Twaddell strength, produces a clear liquid, free from odour, and instead of a useless sediment, a saleable by-product (glauber salts) is obtained. Ordinary water is next impregnated with this carbonic acid gas to about seven times its own bulk, by means of a force pump in a strong copper cylinder, until a pressure of 100lb. per square inch is obtained, when it is considered ready for bottling. Or, water may be thoroughly saturated with carbonic acid by generating the gas in the waters themselves. In either case, about a teaspoonful of fruit essence, syrup, or one of the tonic, stomachic, or phosphoric salts above named, is first put into the empty bottle, which is then filled up with the carbonated water and tightly corked.

Machines are specially made for filling the bottles, siphons, etc., and full instructions are usually given with them.

On uncorking the bottle the imprisoned gas is released, and either escapes or is taken into the stomach in the form of bubbles.

In Soda, Potash, Magnesia, Carrara, and Lithia, the ingredients are apportioned according to the dose recommended by the leading doctors.

A larger amount of gas is usually inserted into soda and potash waters, so as to reduce the temperature of these liquids and enhance their pungency and sparkling qualities.

Sweet beverages, such as Lemonade, Sarsaparilla, Ginger Ale, Orangeade, Champagne Cider, Ginger Beer, etc., are all intended to retain the delicate bouquet of the fresh fruits and spices indicated by their respective names.

For Ginger Ale, or Gingerade, a small quantity of ginger or capsicum extract and sugar is placed in the bottles previous to their being filled up with the aerated water. For Lemonade, essence of lemon, citric acid, and sugar are used.

Most manufacturers mix the water and flavouring matter first, before inserting the carbonic gas. Either way does equally well; the whole cost is very trifling, and it is said a syrup of 14lb. of sugar, 2½oz. of tartaric acid, 3½oz. of citric acid, and 4½ drachms of essence of lemon, dissolved in 2½ gallons of water, will suffice for 30 dozen bottles of lemonade of excellent quality, and that a dexterous bottler can fill and cork them in about forty-five minutes; in fact, the whole process is very rapidly performed by the aid of modern machinery and with a minimum of manual labour. (See also "*Gazogenes.*")

Most of the drinks known as soda-water are merely aerated (carbonated) water, and contain no soda at all; in fact, the public seem to prefer it so, the taste of carbonate of soda not being very agreeable; but the best makers invariably use a little carbonate of soda, and the letter of the law requires it. A well-known effervescing draught is made from bicarbonate of soda and tartaric acid. Carbonic acid always mixes readily in water, the latter absorbing generally about its own volume of gas, hence such beverages do not give off all their gas at once.

If a piece of cork be dropped into a tumbler of lemonade, further effervescence follows, and more gas escapes. Agitation also favours the disengagement of the gas, so that narrow siphons cause more effervescence and froth than the widest bottle necks themselves occasion.

The varying solubility of carbonic acid at different temperatures and pressures explains why siphons and bottles which have been kept in a cold place appear to be "flat," or deficient in gas, when in reality the gas is only kept in solution by the low temperature of the water. It is important that no leaden pipes or other vessels or appliances be allowed to come in contact with these aerated liquids, which readily dissolve lead and have often caused lead-poisoning. Ginger-beer, barm-beer, lemonade, champagne, and other carbonated beverages in which the carbonic acid gas is produced by the natural process of fermentation, are not called aerated but "home-made" beverages or *non-alcoholic brewed beers*, and it must be acknowledged these latter are gaining on the public taste every year, the principal reason being that the objectionable "cloy," hitherto inseparable from aerated waters is absent.

The numerous and valuable waters obtained from natural springs all over the world are usually distinguished as "Natural mineral waters," and aerated waters are merely intended as reproductions or imitations, containing two or three of the substances which are present in largest proportion in the "Natural" waters themselves. To make really good drinks three things are absolutely necessary—pure water, pure ingredients, and well-constructed, suitable apparatus.

Aerated beverages to be consumed on the premises can be sold after 10 p.m. only by parties holding refreshment licences.

It has been stated that there are 30,000 persons employed washing, labeling, filling, and corking, in the London mineral water factories, one firm alone

producing in the summer season no less than three million bottles of these beverages weekly.

Traders should be very careful not to re-fill bottles or syphons bearing other makers' names or trade-marks, this being an offence heavily finable.

"*Camwal*" *Brand*.—The letters "CAMWAL" are simply the initials for Chemists' Aerated Mineral Water Association, Limited.

Aerated Bread.—Bread baked from dough made of flour, water, and salt, without barm, yeast, or any saline matter, but with carbonic acid gas, or carbonic dioxide, mechanically introduced in the form of carbonic acid water, similar to "soda-water."

The kneading—if kneading it can justly be termed—of the water and flour into dough was originally carried on in a special vessel close and strong, so as to maintain the pressure of the carbonic acid gas. When the dough was sufficiently kneaded, it was removed from the close vessel and put into the oven, where it would, of course, expand and rise at once, and thus be baked. The above was Dr. Dauglish's ingenious method as first carried out, but it has been much altered, and the subjoined is the usual mode now followed:—First of all a rather weak wort is produced by working the malt and flour. This mixture is left to ferment, and in due course, owing to the *bacteria*, it sours. Now the water that is to be aerated is mixed with some of this weak acid liquid. It will then be found to readily take up the carbon dioxide gas. The acid, besides, renders the gluten more soft. The resultant aerated bread tastes, it must be confessed, to those who can distinguish well the difference between the various kinds of bread, as somewhat raw, and we need not wonder at this when we bear in mind that there is, unfortunately, in this form of the staff of life, none of that invaluable peptonisation of the albumenoides which result naturally from the process of the ordinary fermentative process. We understand that it was to supply this defect, and to meet the want for a bread that should not taste so crude, that the idea came into operation of adding the fermented wort as a part of the process. There are, we confess, however, some compensative points to allege on behalf of aerated bread. The flours used are both weak and damp and far from excellent, but still it is by this plan practicable to produce thence a form of bread that may still be fairly wholesome and palatable.

It is claimed for this system that it is cleaner, requires no handling; flour is saved, time is saved, the bread being prepared and baked in half an hour, instead of six or eight, and that the bread is pure and more palatable.

The gas is made in the same way as it is made for manufacturers of aerated waters. Five cubic feet of the gas are required to charge 35 gallons of water for every two sacks of flour.

Bakers who have not the mechanical appliances for making proper aerated bread as above sometimes imitate it as follows:—For every pound of Hungarian flour they use a gill of aerated water (brisk as possible), and salt at the rate of 2oz. to the stone. They empty the water into a basin, throw flour upon it, then mix, keeping in as much gas as they can, and in a few minutes put it into the oven.

For small quantities, divide 3lb. flour into two portions; mix up the first with water in which 2oz. bicarb soda has been dissolved. Then mix the remainder of the flour with water to which 1oz. muriatic acid has been added. Knead each of these doughs thoroughly, and then mix both portions together as thoroughly and rapidly as possible; form into loaves, and bake at once.

2. Use a baking powder, composed of 5 parts of Powdered Cream of Tartar, 2½ parts of Bicarb of Soda, and 1 part of flour; all well dried and thoroughly mixed.

These non-fermented breads require well baking, so as to prevent the formation of mouldiness.

They all have a more or less limey taste, arising from the lime employed in the manufacture of the carbonic acid.

Doctors often recommend aerated bread to patients suffering from wind and acid eructations, because fully fermented bread tends to aggravate these disorders, although this latter is much more digestible.

Aerated Flour.—Coomb's Eureka Self Raising Flour undoubtedly commends itself to every lady who prizes herself on her pastry; it being next to impossible to get any other than best results with this flour. It is uniform in quality and blended with scientific knowledge of the various constituents of wheat and flour. It being self-raising also is an additional reason why your results will be perfect. Your pastry will be the admiration of your friends, and, therefore, a perpetual source of satisfaction and gratification to yourself. By its use you will stave off the arch-fiend, indigestion; and there will be no discomfort after eating pastry made from this flour.

It is an admitted antidote for indigestion, and in quality and sheer merit is a long way ahead of all competitors. This is evidenced by the numerous awards, no less than 15 Gold Medals having been secured by this flour.

The leading English, French, and German *Chefs* speak highly of it, and all who know its intrinsic value are determined adherents of this Brand. Sold in 3d., 6d., 1/-, 2/6 bags. Apply to—Coomb's Eureka Flour Co., Ltd., Lenton Boulevard, Nottingham, and 8A Farringdon Road, London, E.C.

Aerated Waters.—See *Aerated Beverages.*

African Coffees.—These are divided into East and West Coast; the former comprising Abyssinian, Bourbon, Egyptian, Mauritius, Madagascar, Mozambique, Nubian, and Zanzibar; the latter including Angola, Benguelan, Congo, Liberian, Loango, and Natal. Each variety is described in its alphabetical order elsewhere.

Africa is the original home of coffee, and trees are to be found scattered throughout that "dark continent," but its cultivation so far is comparatively trifling.

African Lard.—A rich and beautiful hard butter obtained from the nut of the *elais guineensis*, a native tree on the coast of Guinea.

For cooking purposes it excels the finest ordinary lard.

Agar-agar.—A Malay name for the well-known gum obtained from *Escheuma spinosum*, etc., and which also includes several other yellow gelatinous and edible sea-weeds, common to the coasts of the Archipelago, such as *Ceylon Moss, Java Seaweed, Bengal* or *Japanese Isinglass, Australian Algæ* etc. The fucus is now generally referred to the *Sphærococcus spinosus*, and *gracilaria* of Agardt. The best qualities are used in cookery, after being boiled in water until well dissolved, and then simmered into a jelly transparent as water, and finally dried in the form of thin sheets; but they are not so easily dissolved by heat as ordinary gelatine. The inferior kinds resembling Irish and Iceland Moss are largely used in preparing paste for microscopic fungi, and as a coating for paper in making native lanthorns.

Agar-agar is also used as an ingredient in making size for silk manufacturers. It is generally seen in thick yellowish-white pieces about an inch wide and a foot long, and sometimes in white transparent threads, thick as a straw, and about two feet long. It is usually imported in bales of 200lb., mostly from Singapore, and sold retail at 2/- to 4/6 per lb.

Being full of cavities, the best Agar-agar is extremely light, and quite tasteless. It swells out very much in water, and on heating forms a jelly-like food for invalids, and will keep good for a longer time than other jellies. 1oz. will make 5 to 10 pints.

The natives in India prefer Agar-agar in place of Isinglass, to which, being an animal substance, they have religious objections. Apply to M. E. Holdsworth, 3 Norfolk Street, Bradford.

Agaves. — A genus of plants not unlike aloes, with which they are often confounded. Agaves are native of

Central America and Mexico, but have also been naturalised in Europe. (See *Pulque*.)

Agi or **Aji.**—Names for the Guinea or Red Indian dwarf bird-pepper, a species of capsicum, grown in Peru; also a sort of sauce made from it in America.

Aipi.—A Brazilian edible root from which a beverage is also extracted.

Aizen.—A liquor prepared from cows' milk in Tartary.

Akee.—A kind of fruit (*Cupania sapida*) native of Guinea, but now grown extensively in the West Indies and South America, and quite distinct from the New Zealand shrub *Aki*. The tree grows 20 to 30 feet high, with white flowers, from which a native cosmetic is made. The fruit is of a reddish-yellow colour, a little larger than a hen's egg, is divided into three lobes or cells, has an agreeable sub-acid flavour, and is very delicious. It is considered beneficial in cases of diarrhœa, and is very popular in Africa.

Albacete.—A Spanish wine of medium quality made in New Castile.

Albo-carbon.—A solid residuum of creosote. An "*albo-carbon light*" is a light produced by carburetting ordinary gas by the volatilisation of albo-carbon, which is prepared in a fluted form and placed in cylindrical chambers about the gas-burner.

Albumen.— The purest albumen is found to the extent of about 12 per cent. in the white of eggs, and may be prepared for use by dissolving in cold water, and then beating to a froth. A considerable quantity of "egg white" is manufactured in Russia and Germany.

It is also prepared in China. At Hankow there are three large European firms—one Austrian and two German—engaged in the business. Immense numbers of eggs are used, and as they must be fresh, the season is restricted to two periods of about two months each year.

A large amount of egg albumen is now made by a German firm at Wuhu, near Chinkiang, in Eastern China, where duck eggs are very cheap and plentiful. As soon as the eggs are received at the factory, they are tested by a very simple but ingenious process. They are held in pairs in front of a circular opening in a tin cylinder open at the top, containing a lamp giving a powerful light, which is concentrated on the opening. Each speck or flaw in the egg is distinctly seen in the process, and all the eggs showing the slightest defect are at once rejected. The percentage of rejected is remarkably small, rarely amounting to 50 per 1,000. The good eggs are sent to the room prepared to receive them, where a number of Chinese girls are employed to break and separate the yolk from the white, placing each into separate vessels. The white then undergoes one or two processes. It is either carefully cleansed of all stray bits of yolk, and then put through a course of stirring in a large vessel, by means of a large heavy rod or paddle worked by hand, when it is ready for the drying-room, or, after being cleaned, it is run into large vats and allowed to ferment, the process of fermentation being accelerated by the admixture of certain chemicals, which chemicals are held by the firm as a secret. When it is found in drawing off that all the impurities have either been deposited or thrown off in the form of a thick froth, and the resulting liquid is albumen, as clear as water, the albumen is ready for the final process of drying. This is performed in a series of three rooms, each hotter than the last, the temperature ranging from 40° to 50° Centigrade.

The albumen is run into shallow tin pans about 1 foot square, which are placed in ranges of shelves in the drying rooms. Frequent examinations are made to see the temperature is maintained, and that the process of drying is sufficiently gradual, uniform, and complete. A period of sixty to seventy hours usually suffices. When thoroughly dry the albumen, which now presents the appearance of isinglass, with a yellow tinge, is, after cooling, placed in large square packing cases lined with tin, holding

about 400lb. each, and is ready for shipping.

Albumen is largely used by confectioners as a glaze for pastry goods, and to clarify wines, sugars, coffee, syrups, etc., but its principal use is in the preparation of fast dyes for superior kinds of cotton goods, prints, etc., also in photography.

Seven hundred eggs will yield about 10lb. of albumen and from 50lb. to 60lb. of yolk.

Albumen occurs also in the sap or juice of many plants, fruits, and vegetables, such as peas, turnips, cabbages, potatoes, etc.

About 1,000 tons come to this country yearly; formerly there was a demand for dried albumen at 5/- to 7/- per lb., but it has decreased since the introduction of aniline dyes, and now only fetches 1/- to 3/- per lb.

For prices, etc., write to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Alcarnose.—A German extract of meat, which is put up in egg-shaped capsules, one of which dissolved in a cup of hot water makes a cup of *Bouillon*.

Alcohol.—F. *Alcool;* Ger. *Alkohol, Weingeist;* It. *Spirito ardente, alcool.* (See also *Spirits, Potato Spirit, Silent Spirit,* etc.)

An ardent spirit, transparent and colourless, obtained by distillation and rectification from any fermented liquids; and when perfectly free from water, it is termed absolute alcohol, represented by C2 H6 O; in other words, Carbon 52.2, Hydrogen 13.0, and Oxygen 34.8. It has usually a sharp, penetrating, but agreeable spiritous smell and burning taste.

The term alcohol, although frequently given to any spiritous liquors, is properly applied only to highly-rectified spirits of wine.

The dilute alcohol distilled from wine or fermented grape juice is called *brandy*, that from the fermented juice of raw sugar, *rum*, and owe their flavours to the wine and sugar.

Alcohol is also derived from many other fermented products of saccharine, vegetables, fruits, and grain.

During the last two or three years immense quantities of alcohol have been produced at the maize factories and the cane sugar factories in Argentina, and at extremely low prices.

It is remarkable how alcoholic products have engaged the attentions of certain religious orders. In Helyot's "*Histoire des ordres monastiques*" we read that in the seventeenth century the art of distillation was largely carried on by the Jesuits, under the pretext of preparing mendicaments for the sick poor. They got the name of *Padri dell' acqua vitæ*, and the business has long had a special attraction for the good fathers. Witness the *Chartreux*, *Trappistes*, and *Bénédictines* of to-day.

Alcohol never freezes, and is the only fluid that will dissolve certain gums, resins, and some other substances.

It is lighter than water, and very inflammable.

Its purity may be tested by its specific gravity, and its keeping its clearness when mixed with a solution of nitrate of silver.

Absolute alcohol, as stated above, means pure alcohol without any water—the Brit. Pharmacopœia says it should have the spec. grav. of between 0.794 and 0.7969—but absolutely pure alcohol is rarely met with, for the atmosphere itself would soon dilute it. In its strongest distilled form it contains 10 per cent. of water, hence commercial strengths vary; 70 per cent. strength means that in 100 parts of the fluid there are 70 parts of absolutely pure alcohol and 30 per cent. of water.

But there is a legal standard of spirits, which is called "Proof," and consists of 100 parts, viz., 50.76 parts by weight of water to 49.24 parts by weight of alcohol.

Proof Spirit is, therefore, an assumed standard of strength at the specific gravity of 0.920 at 60° F., from which standard the comparative strengths of all spirits are usually determined. In England a spirit having a sp. gr. of 0.838 is said to be 54 to 58 over-proof. When spirit is O.P. (over-proof) it is reduced to *proof* by the addition of water, spirit which is 10°, 20°, or 40° O.P. requiring

to each 100 gallons of spirit 10, 20, or 40 gallons of water to reduce it to proof.

Under-proof Spirit, said to be 10°, 20°, or 40° U.P. (under-proof), means that 100 gallons of the liquid contains 90, 80, or 60 gallons of proof spirit, and 10, 20, or 40 gallons of water.

The ordinary percentages of absolute alcohol in wines and liquors are: Beer, 4.0; Porter, 4.5; Ale, 7.4; Cider, 8.6; Perry, 8.8; Elder, 9.3; Moselle, 9.6; Tokay, 10.2; Rhine, 11.0; Orange, 11.2; Bordeaux, 11.5; Hock, 11.6; Gooseberry, 11.8; Champagne, 11.2; Claret, 13.3; Burgundy, 13.6; Malaga, 17.3; Lisbon, 18.5; Canary, 18.8; Sherry, 19.0; Vermouth, 19.0; Cape, 19.2; Malmsey, 19.7; Marsala, 20.2; Madeira, 21.0; Port, 23.2; Curacao, 27.0; Aniseed, 33.0; Maraschino, 34.0; Chartreuse, 43.0; Gin, 51.6; Brandy, 53.4; Rum, 53.7; Irish Whisky, 53.9; Scotch, 54.3.

It must, however, be remembered that most of these compounds differ considerably. The Bordeaux Aniseed of Marie-Brizard is only 27, while Cointreau's "Triple-Sec" (a white Curacao) is 40. Green Chartreuse is 58, but yellow and white only 43.

When alcohol is oxidised, it is converted first into a substance known as *aldehyde* and finally into *acetic acid* (see ACETIC ACID). The "alcohols" in organic chemistry denote a series of bodies, similar in composition to spirits of wine, which is distinguished as *ethyl* alcohol, while wood-spirit is termed *methyl* alcohol, and so on. Alcohol was first distinguished as an elementary substance by Albucasis, in the 12th century. The word is derived from the Arabic article *al* and *kohol*, to paint with a preparation of powder of antimony. Oriental women still practise the painting of the eyebrows with this material. The name was applied to this substance, and afterwards to other fine powders, and to highly rectified spirits.

In France and England alcohol employed for industrial purposes is exempted from a large part of the usual duty on spirits, providing it has been previously mixed with 10 per cent. of wood-spirit, which renders it unfit for the manufacture of intoxicating liquors, but does not impair its usefulness in other respects; this substance, known as "methylated spirit," is invaluable to the scientific and manufacturing chemist.

The Excise Board will not allow chemical dealers in this country to sell absolute alcohol without paying a heavy licence duty, which is out of proportion to the profits made by selling the article. The Customs impose no such restrictions on the foreigner so long as he pays the ordinary spirit duty. The consequence is that most of the absolute alcohol used by chemists in this country has been imported from Germany for many years. As the substance is solely used as a pure chemical, it is now largely imported in iron cylinders; but some comes also in tins by parcels post, and the postman collects the duty for the Customs on the delivery of the parcel.

Ale. — Dan. and Sw. *öl*; F. *biere*; Ger. *bier*, *äl*; Ir. *ol*; W. *cwrw*. (See also *Beer*, *Bottled Ale*, *Lager*, *Stout*, etc.)

Ale is a very old beverage; it was a favourite drink of the Anglo-Saxons and other ancient inhabitants of Europe, and was brewed from barley malt, but without hops; ivy berries or "ale hoof" (*Nepeta glechoma*) being used for imparting the bitter flavour. Fermented wheat, millet, rye, oats, etc., are now frequently used. Hops were first introduced in 1524 from Germany after many previous attempts to do so had been defeated by Parliament, and it was thus the German word beer (or *bier*) was first used to distinguish the hopped liquor from "*ale*," the un-hopped. Ale has always differed from beer in having *less* of hops and hence being sweeter and of lighter colour, but most of the finer kinds of ale are now highly hopped, or bittered, to make them keep better, especially ales for exportation and changes of temperature, and are now very fashionable in this country—particularly in summer. Ordinary ale intended for quick consumption need not contain any hops, and is often made entirely of pale malt, and the lower priced of these *mild sweet ales*, as they

are termed, are, as a rule, more nutritious than the strong bitter kinds.

Scotch ales are distinguished for the small quantity of hops they contain, and for their vinous flavour. The best *Edinburgh ales* are of pale colour, mild, glutinous, and adhesive; they are much stronger than *Porter*, from four to five bushels of malt being used to the barrel, and one pound only of hops to each bushel of malt. Excellent ales are also brewed at Alloa, Prestonpans, Belhaven, and other Scotch towns.

Highly coloured ale is made by adding to the malt a quantity, as may be desired, of strong, dried, and charred malt.

India pale ale is made with an extra supply of hops. There is no class of ale that tries the capabilities of the brewer as does *pale* ale. The hops should be the best, and neither be green nor too high coloured, and yet not such as to cause slackness or unsoundness. Saccharine is an important ingredient, and the best pale ales contain one part of saccharine to three of the finest and highest dried malt.

Burton ales, *Devonshire white ales*, etc., are referred to under their respective headings.

October and March are the best brewing months, the temperature of the air then permitting the cooling of the wort.

Strong ales are mostly made from the best pale malt, and the fermentation takes place slowly, so that the ferment is exhausted and separated; this and the large amount of undecomposed sugar remaining enables the liquor to keep long without a large amount of hops. XXXX—Few persons in the trade at the present day know the origin of the cabalistic X's with which some brewers ornament their casks so profusely, but in bygone times, in distinguishing between *small beer* and *strong*, all ale or beer sold at or above 10/- per barrel was reckoned to be *strong*, and was therefore subjected to a higher duty. The cask which contained this strong beer was then first marked with an X, signifying *ten*, or ale of the lowest quality; and hence the present quack-like denominations of XX (double X, or double strong, or ale of the second quality) and XXX (treble X, or ale of the third quality) which appear unnecessarily on the casks and in the accounts of the strong ale brewers. The more X's the stronger the ale is *supposed* to be; but a small country brewer, one day receiving an order for eighteen gallons of "strong" ale, promptly proceeded to rack off this quantity from a "cleanser" of running ale in the cellar. He then stencilled four X's on the cask, and when asked why not add another X, replied, "*Because the cask ain't big enough.*"

Sugar, glucose, rice, maize, gingelli seeds, aloes, wormwood, and numerous other substances are said to be employed by some brewers. Ales have been found adulterated with salt, *coculus indicus* (a very noxious intoxicant), grains of paradise (hot and acrid), chicory, sulphate of iron, powdered quassia-wood, alum, etc. It is notorious that a few years ago, when hops were extraordinarily scarce and dear, many new brewing substitutes were introduced, and still continue to be largely employed; and it is to be hoped that, notwithstanding the opposition of brewers and teetotal faddists, the "free mash tun" will soon be looked into, and pure ales again made entirely from barley, malt, and hops.

In Belgium and certain other countries the use of lead pipes in connection with beer machines is strictly prohibited.

A few years ago beer was brewed by a much greater number of persons, in proportion to the output, than is now the case, and every brewer had his own way. Many local peculiarities exist as to beers. For instance, at Nottingham a somewhat deep-coloured beer is preferred, while at Sheffield, only 40 miles off, it must be as pale as possible. In the latter town porter is scarcely ever drunk, while at Manchester, yet another 40 miles, it is highly popular. At Birmingham and in Sussex ale is stronger than beer; in the West Riding, exactly the reverse is the case.

Ale keeps best in underground stores at a temperature of 44° to 50°F.

Sour and muddy ales.—To remove acidity and sourness a few grains of carbonate of soda may be stirred into a glass of ale just before drinking, but if put in too long before it turns the ale "flat."

To fine or clarify ale of a dull or muddy appearance, draw a pint or so off into a bucket, stir in some "finings" till it is of the consistency of treacle, strain it through a piece of canvas to make sure it is all reduced to equal thickness, then add more ale till thin as cream, and again add more ale, and stir the whole well to a froth, draw out the large bung in the middle of the cask and with a funnel pour in the whole, also draw off a pailful at the bottom and pour it in again at the top. Then replace the bung and let the liquor rest for a week or so.

When ale tastes too new, put a sliced Seville orange into the cask.

Alegar. —An old name for sour ale converted into vinegar, now mostly used for dyeing purposes. The large amount of nitrogenous and other extractive matters which sour beers contain undergo a second or putrid fermentation after the alcohol has been oxidized into acetic acid, and in doing so reacts upon the acid, leaving the liquid of a very disagreeable odour. By adding a little sulphuric acid, this second fermentation may be postponed for some time, but the vinegar has, nevertheless, a very nauseous smell, which renders it objectionable. It has none of the pleasant flavour of genuine malt vinegar brewed in the modern way.

Alenquer. — A cheap kind of red Portuguese wine, produced in Estremadura; similar to a low-class Bordeaux.

Alexandrian Coffees.—A general term for Egyptian coffees which are shipped through the port of Alexandria.

Algaroba Beans.—See *Locust Beans.*

Algerian Tea or **The Arabe.**—The flowers of *Paronychia argentia* and *P. nivea*, used as a medicinal tea in Algeria, and thence imported into France, where it is well known as *Thé Arabe.*

Algerian Wine. — See *French Wines.*

Algin or **Sodium Alginate.** — A glutinous mass manufactured from seaweed.

It resembles new cheese, and will keep any length of time if stored in an ordinary cool drying-room. By adding a little bleach it can be made perfectly white. It can easily be dissolved by carbonate soda in the cold for use.

The evaporation is effected in the same way as gelatine, in thin layers on slate shelves in a drying-room with a current of air, or on revolving cylinders heated internally by steam.

The solution keeps well.

Thus obtained, the sodium alginate presents the form of thin, almost colourless, sheets, resembling gelatine, but very flexible. The solution can be precipitated or coagulated with citric or tartaric acid or lime water. It contains nitrogen. It won't coagulate by heating. It won't gelatinize on cooling. It dissolves in weak alkaline solution, but is insoluble in boiling water.

As an article of food, *Algin* contains—Carbon, 44·39; hydrogen, 5·47; nitrogen, 3·77; oxygen, 46·37, or about the same amount of nitrogen found in Dutch cheese.

It has a slightly pleasant marine taste, easily overcome if objected to, and may form a useful addition to the kitchen for thickening soups and puddings.

It appears specially adapted to replace gum arabic in the manufacture of jujubes and lozenges.

To make it into jelly requires addition of gelose or gelatine or admixture of lemon juice.

It is useful for emulsion of cod liver oils, as an excipient for pills, and for fining of spirits.

Alicante Raisins. — Raisins produced in the province of that name in Spain.

Alicante Wines. — Rough sweet Spanish wines, of which Alogne and Vino Tinto (red tent wine), from the province of Alicante, are best known; when old the latter sort is called Fondellol—

alcoholic strength, 14 to 15 degrees. They are both of very red colour and often used to manipulate thin clarets for the British market. The ordinary wine of Alicante is of sound quality and generally very cheap, say £4 or £5 a pipe, according to season and quality.

Alimental Oils. — See *Edible Oils.*

Alkali or **Alcali.** — F. It. Sp. *Alcali;* G. *Alkalien;* Per. *Kaliab.*

A term applied to such chemical bases as potash, soda, ammonia, and the like salifiable substances which have the following properties in common: solubility in water, the power of neutralising acids and forming salts with them, the property of combining with fats and oils to form soaps, corrosive action on animal and vegetable tissue, the property of changing the tint of many vegetable colouring substances, as of litmus reddened by an acid to blue, or turmeric from yellow to brown.

In its restricted sense the term is applied to the hydrates of potassium, sodium, lithium, cæsium, rubidium, and ammonium.

In a more general sense it is applied to the hydrates of metals, of the alkaline earths, barium, strontium, calcium, and magnesium, and to a large number of organic substances, both natural and artificial, such as morphine, nicotin, quinine, etc. Potash, soda, and lithia are called *fixed* alkalies in contradistinction to ammonia, which is called a *volatile* alkali.

Alkanet, Alcanna, or **Anchusa Root.**—Du. *Alkana*; F. *Orcanette*; Ger. *Orkanet*; It. *Ancusa*; Sp. *Alcaneta.*

A deciduous herbaceous plant, *Anchusia tinctoria,* grown in France, Siberia, Spain, Hungary, etc. (but the English climate is too cold in spring), bears dark blue flowers, has a dark blood-red root, yields a substance scarcely soluble in water, but used as a brownish-red colouring material. Only the outer skin of the root is used, so that the smaller roots are most valuable, the inner parts of large roots being white and valueless. Freely soluble in either acetic acid, oil, or spirits, it is largely employed in staining furniture, in imitation of rosewood, and, like Dragon's Blood, for giving a crimson colour to oils, fats, cheese, wax, spirits, pomatums, varnishes, essences, etc., by simply placing it in them. It is also used for colouring factitious port wines and the corks to give them the appearance of age and genuineness. Several other Boraginaceous plants with red roots, such as *Onosma echioides, Arnebia tinctoria,* etc., are often substituted.

Alkermes.—A liqueur much used in Tuscany, Spain, etc., made from bay-leaves, mace, nutmegs, cinnamon, and cloves. These spices after being well bruised are mixed with brandy, and the whole is then subjected to distillation. The product is afterwards flavoured with an extract of *Kermes berries* (*Coccus ilicis*), small insects about the size of peas, found on oak trees on the shores of the Mediterranean.

Allcock's Porous Plaster.—India-rubber, 1 lb.; pitch, 8 ozs.; gum thus, 8 ozs.; and cayenne pepper, 30 grains, the last ingredient being added when the others are previously melted. The mass is then spread on muslin or linen perforated with small holes, allowing vent for perspiration and affording increased flexibility.

Allen's World's Hair Restorer.—An ordinary bottle contains about 75½ grains of sulphur and 87 grains of lead acetate, with 8 ozs. of water.

Alligator Pears.—A common name for *Avocado Pears.*

Allonya Tubers or *Topee Tamboo.*—These small tubers are used as food in the Island of Trinidad. They are of globose or egg shape, all bound together by stalks, thus forming the large ovate bulbous root of the plant *Calathea Allonya,* one of the *Scitamineæ.* The smaller tubers are usually selected for edible purposes, being boiled and eaten like the ordinary potato, with milk and salt.

They have an agreeable nutty flavour and contain very little starch, but a relatively large amount of gummy matter.

Allspice, or Jamaica Pepper.—F. *Toute-épice, Piment de la Jamaique.* Old-fashioned names for *Pimento*, which see.

Almeria Grapes.—See *Grapes.*

Almond Drops (*Biscuits*).—The following is an average mixing for above :—4½lbs. flour, 1¼lbs. margarine, ½ oz. baking powder, 4½lbs. sugar; when rubbed, make a bag, add fourteen eggs and a little essence of almonds, roll in long fine strips, cut off in half inch pieces, stand on ends half an inch apart and bake in a cool oven.

Almonds.—Da. and Sw. *Mandel;* Du. *Amandelen;* F. *Amandes;* Ger. *Mandeln;* It. *Mandorle;* Port. *Amendoas;* Sp. *Almendras;* Sw. *Mandlar.*

The fruit of the almond tree, *Amigdalus communis*, of which there are two kinds—the *A. c. var: dulcis*, or sweet, and the *A. c. var: amara*, or bitter. The tree itself is a native of Africa, but thrives throughout Southern Europe, and is largely cultivated in Italy, Sicily, Sardinia, and the Greek Archipelago, Spain, France (especially Provence and Languedoc), Malta, and the East. It grows twenty to thirty feet high, and has flowers before leaves. Although almond trees flourish almost anywhere between 27° and 45°N. latitude, they seem to prefer a mean annual temperature of about 58°F. and thrive best in low sunny grounds of light soil, sandy or gravelly, but not clay. In France the average yield is 12lbs. per tree, but in California it reaches 20lbs. per tree. When growing on the tree the fruit is covered with a hard green shell, which dries as it ripens in August, and at last opens, when the almond falls out. The eye can discover no difference between the trees, leaves, or fruit of the sweet and bitter kinds. The bitter kernel is often thicker, but smaller in size, than the sweet kind. It is fancied that the *bitter* almond is the product of the wild ungrafted tree with its white blossom, while the *sweet* is that of the cultivated and grafted one with pink blossom. The two great commercial divisions are *Shelled almonds* (Amandes Cassees) and almonds in the shell, or *Unshelled* (Amandes en coques), but they are of great variety, certainly over 500, and all have a pleasant nutty aroma. They reach England in the ember months. *Jordan* are considered the best; they are large, sweet, flat, and oblong, less pointed at one end, and less rounded at the other, and have paler skins. They have also thick hard shells, and are very extensively imported, without the shells, from Malaga in boxes. Other Malaga varieties are almost cylindrical in shape, and these have a remarkably fine flavour. The bulk of the almonds in the shell sold in England come from Faro, Tarragona, and Barbary.

Valentia Almonds are another highly-valued species. They also are large and sweet, but broad, flat pointed at the end, and compressed in the middle. They also come without the shell from Malaga.

Nearly every kind of almond is grown in Spain, where they are divided into two general classes—the sweet (*almendras dulces*) and the bitter (*almendras amargas*), the former being cultivated chiefly in Alicante, and are of five varieties: *Pestañela, Bale, Blancal, Mollar,* and *Comun.*

In 1894 Spain exported, in shells (*Amandes en coques*), 1,430,000 Kilos, and without shells (*Amandes cassées*), 3,475,000 Kilos, mostly to Great Britain, France, and the U.S.

France also produces two varieties of almonds in the Bouches du Rhone department, Aix and Salon being great centres for this trade. The best are called Princesses, and the others Lady almonds. Marseilles is the port of shipment, and the bales contain 120 to 150 Kilos. Sweet almonds are eaten in dessert, and, taken in moderation, are nutritive and demulcent; but, consumed in large quantities, they are purgative.

The climate of the middle and south of France is well adapted to the growth of almonds, and in the summer they are commonly sold, while green and tender

and both shell and husk are soft (like green walnuts), by the dozen or hundred in the country markets at from one farthing to 2½d. per dozen. The meat is then quite white and creamy.

Bitter Almonds (Amandes ameres) are usually imported in boxes from Barbary and Mogador. They contain a great quantity of prussic acid (a deadly poison), and, besides their bitter taste, may easily be known from the peculiar odour they give out when rubbed with water. If used in cooking or confectionery, it should be with great caution, *even small* quantities having been known to produce nettle-rash and other unpleasant symptoms. When "*Almonds*" merely are asked for in the shop, the *sweet* kind should always be supplied. Both kinds are sold shelled (without shells) and unshelled (in the shell), and contain about 50 per cent. of an aromatic oil, with other constituents in common, and are used whole or in part in very many kinds of sweetmeats, pastry and drinks. The *bitter almond* is generally compressed for its oil (H C N), and the remaining cake is mostly used as a cosmetic. Brandy or ammonia may be given as an antidote for almond poisoning.

The Dwarf Almond.—A. nana is a common double-flowering variety. It is a mere shrub, growing but two or three feet high, in Russia. The fruit is very small. Almond trees, especially the Dwarf, are not unfrequently met with in England and other Northern countries, where, although the fruit never matures, they are grown for ornamental purposes, and for the large and early spring blossoms so highly prized by English brides.

Green Almonds are sometimes preserved in sugar like apricots. They are the young fruit of the sweet almond trees, and may be eaten green or dried, and sometimes converted into *orgeat*, a very refreshing summer drink.

Blanched Almonds are prepared by soaking shelled almonds for a short time in hot water, after they have been hand-sorted into different sizes, when the skins, husks, or seed-coats are easily removed between the finger and thumb. The translucent white tegmen, or inner coat, comes away at the same time. In well-appointed factories this is done by passing the almonds through a machine with revolving cork rollers. The rollers are so set that they exert just sufficient pressure to burst the skin, without bruising the kernel. The almonds are afterwards rinsed in cold water, drained, and wiped dry. If they are to be kept some time, or ground, they should be slowly dried by a warm stove or in the air or sun. Sometimes the blanched product is cut or shred; if shred, the mass is dried thoroughly in hot revolving pans and used in a desiccated condition. See also "*Burnt Almonds.*"

Apply to Kimpton Brothers, 36 and 37 Mincing Lane, London, E.C.

Almonds (Essence of). — For flavouring wines, cordials, liquors, perfumery, pastry, and other culinary productions. Generally prepared by mixing one part of the essential oil of almonds with sixteen to twenty-four parts of rectified spirits.

The oil obtained from *bitter* almonds being very poisonous (four times stronger than prussic acid), the essence from it should be made very weak.

Much confusion exists as to what is essence, what is essential oil, and what is pure or genuine oil of almonds. In America, what in England are classed as essences — spiritual essences — are called *extracts*, and essential oils are there called essences. In the case of almond oils, essences, or extracts, it is highly important to be certain as to which is intended.

For essences of all kinds, apply to Charles Cocks and Co., Reading, Berks.

Almond Oils.—There are two distinct kinds of almond oil, viz., the *essential oil* and the expressed fixed oil of almonds. They are both of a thin pale yellow colour, whether expressed from the sweet or bitter almond, and almost odourless, but with a bland oleaginous and nutty taste. Bitter almonds are submitted to powerful hydraulic pressure, by which means

the contained fixed oil is expressed. The residual cake is then treated with water, and the mixture distilled, the essential oil now passing over. The almonds do not contain the volatile oil ready formed, but the materials necessary for its production. These are a glucoside called amygdalin, to which is assigned the formula $C_{20}H_{27}NO_{11}$, and emulsin, a substance belonging to the class of albumenoid ferments. The distilled oil of bitter almonds is ten to twenty times stronger than the spirituous "*Essence of Almonds*," and contains a dangerous amount of hydrocyanic acid, or prussic acid—about 13 per cent., but is generally more or less purified by a dilute solution of potassa, or by treatment with iron in *aqua-regia* solution and distilling with lime water.

It is often found to be diluted with ordinary sweet oil, and imitated with oil from peach kernels.

A factitious oil of almonds, known also in trade as *nitro benzole*, *oil* or *Essence of mirbane*, etc., is now extensively prepared and sold as a substitute for the genuine oil of bitter almonds.

It is really a compound of concentrated nitric acid and benzole.

Best English prepared oil of bitter almonds, freed from prussic acid, is worth about 28/- per lb.; foreign, 15/-; with prussic acid, 13/-; and the factitious kind, about 2/6 per lb.; sweet genuine (*i.e.*, the fixed oil obtained by pressure and which contains olein with some stearin, palmitin, etc.), 8d. to 1/- per lb.

True almond oil consists chiefly of olein, and its congealing point is therefore very low, namely 4° below zero F.

In buying or selling almond oil it is highly important clearly to understand what is really required and for what purpose.

For prices, etc., apply to C. Windschuegl and Co., 1 Leadenhall Street, London, E.C.

Almond Soap.—Also called *Amygdaline Soap*. Generally made of common soap, coloured dark yellow, and scented with almond oil and sodium hydrate—say twenty-one parts of first and ten of latter. Common sorts are often scented with nitro-benzole to imitate almond odour and to hide disagreeable smell.

Almond Syrup.—See *Orgeat*.

Aloes.—The bitter and purgative juice extracted from the fleshy leaves of certain trees, such as *Aloe vulgaris*, the Common or Barbadoes Aloe (which grows wild in India, Spain, and the Canaries, and is cultivated in the West Indies), the *Socotrine Aloe*, imported via Zanzibar and Bombay, and the Cape Aloe (*A. spicata*) etc.

Imports, about 300 tons annually, are commercially classed as Socotrine, Barbadoes, Cape, or Hepatic.

Alogne Wine. — See *Alicante Wines*. Da. *Allun*; Du. *Aluin*.

Alum. — F. *Alun*; Ger. *Alaun*; Du. *Aluin*; It. *Allume*; Sp. *Alumbre*; Port. *Pedrohume*; W. *Allawg*.

A whitish, lumpy, saline substance or *double-salt*, a combination of aluminia with sulphate of either potash, soda, or ammonia. When pure and fresh it is brittle, odourless, and almost colourless, has a sweetish, aciduous, and very astringent taste. It used to be produced largely at Hurlet and Campsie, near Glasgow, from alum-slate or shale; also near Whitby, Yorkshire; but now it is chiefly manufactured at Goole, Newcastle, and Manchester. A great weight of this argillaceous schist being required to produce a small quantity of alum, the manufacture has to be carried on as near as possible to where the former is found. In medicine alum is an important and powerful astringent; it checks hæmorrhage, diminishes secretions, and is frequently administered in cases of diarrhœa, and is perhaps the most successful remedy known for *lead-colic*.

From its powers to contract and to corrugate the animal fluids and tissues it is often used as a gargle, a wash, or an injection. Ground or powdered alum dusted over a leech-bite, prick, or slight cut is good for stopping the bleeding.

It is also used in tanning and in

candlemaking to whiten the tallow; also for clarifying liquors.

Alum often contains traces of iron, but this is injurious and may easily be discovered by adding a few drops of water in which bruised nutgalls have been boiled, when the solution will show a purple tint.

Ground or *Powdered Alum* is often used by bakers to make white bread from cheap dark flour. It also imparts to the bread the property of absorbing and retaining, after it is taken out of the oven, a larger quantity of water, but this is denounced as an injurious adulteration, and renders the offender liable to a severe fine and exposure.

It is also often used in baking powders to help to keep them dry and fresh in appearance, but is finable.

Alum Water is frequently used as a wash for old sores, and diluted with rose-water as an eye-wash. It is also used to whiten sugar in manufacture.

Muslin dipped in a solution of alum is rendered incombustible. This salt is also used to fix vegetable colours in cotton goods; such colours being then called "fast."

Rock, *Roche* or *Burnt Alum* is alum crystallised and deprived of its water by heat, and thus forms a mild escharotic for external use.

Alva or **Aiva.** — A conserve of quinces, forming an article of commerce in the East.

Ama Tsja or **"Tea of Heaven."** —A kind of tea prepared in Japan from the leaves of *Hydrangea serrata*, or *Thunbergü*.

Amatimgulu, or NATAL PLUMS.— The fruit of *Carissa grandiflora*, first imported into England, from Africa, about 1862, varying in size from an olive to a plum, and possessing a milky sub-acid juice, due to caoutchouc. The flavour is pleasantly acid, and very refreshing, but these fruits are rarely to be met with in this country.

Ambergris. — This odoriferous substance, the most costly of the animal perfumes, obtained its name from the fact that an antique author, Robert Boyle, considered it to be of vegetable production, and similar to yellow amber, hence it was dubbed amber-*gris* (grey amber). In the "*Arabian Nights*," "*Sindbad the Sailor*," and many other works, equally plausible, but fallacious, theories have been put forth regarding it. It has, however, been ascertained beyond a doubt to be generated by the large-headed sperm-whale (*Physeter macrocephalus*), and is the result of a diseased state of that animal. The disease is in the intestinal canal, and the victim may throw off the morbific substance, or may die of the malady. When discovered, the fetid mass is carefully taken from the bowels of the whale, and is packed in casks, if it is in liquid form, or in sacks if it is dry enough. Sometimes it is found to be in a rank liquid state, sometimes of the consistency of soft putty, and at other times a chalk-like substance. That which is like putty is preferred for the market, and when dried the dark shade gradually turns to a soft squirrel-grey. It lightens in weight, and develops an odour like the blending of new-mown hay, with the perfume of the violet. Crude ambergris, obtained by the whale fishers of New Bedford, or Provincetown, is shipped to France, where, more than anywhere else, it is prepared so as to give lasting qualities to the more fleeting scents. In the East it is used in cookery. Market grades, 20s. to 80s. per ounce.

Amboyna Cloves.—A small dark-coloured variety, considered of superior quality to ordinary cloves, and fetch highest prices. (See *Cloves*.)

Amel Wheat.—See *Gommer*.

American Apples.—(See also *Dried Apples, Green Fruits, etc.*)

These include apples from the U.S. or from Canada, and are all of excellent quality.

Apple trees were first introduced into America from England in 1629, by the Governor of Massachusetts Bay. The crop is now about ten million barrels a year.

The chief standard varieties of winter sorts are the Russets, Baldwins, Spitzenbergs, Greenings, Kings, Canada Reds, Ben Davis, Spys, and Newtown Pippins.

The "Ben Davis," or turnip apple, is rather a peculiar cooking apple. Having no particular flavour of its own, it readily takes the flavour of any other fruit with which it may be cooked. It keeps well all the year round, and never rots, even when considerably bruised. Frost never injures it, but it is not generally liked, any more than our own unfortunate "Sturmer Pippin," and is considered very coarse and flavourless. Immense quantities are grown in Canada, particularly in Western Ontario, where the trees bear so heavily that they have to be supported, and the fruit in bumper years is too cheap to pay for gathering.

The Canada "Duchess" is a very useful variety of medium size, pale green in colour, with a few dull red longitudinal streaks at its base.

"*Kings*" take their name from King's County, in Nova Scotia, where large quantities are grown.

The best apples grown in America are left on the trees till the middle of October, when they are hand-picked, and placed softly in clean barrels. The barrel is gently shaken three or four times during the filling, so as to secure close packing, and when the barrels are full, and well heaped up, they are placed in a press, or "barrel-header," and the heads or bottoms are pressed on by a special hand-lever, the apples being thus more or less pressed into each other; but this does not injure them much, as one fruit stays where pressed into another, and air is excluded. The indentation from the pressure merely impacts the juices, and there is less decay than by loose packing. It is, in fact, the action of air which causes decay. The apples are usually left in some cool place till frost sets in, when the barrels are stacked on their sides in cellars, but it is only in those parts of America where the autumns are cool that apples can be raised for preservation.

In Mills County, Iowa, there is an orchard 1,000 acres in extent, and containing 110,000 apple trees. The grades exported are "firsts," "seconds," and "thirds."

The refuse and damaged apples yield Cider of inferior quality, and the pomace, when washed, yields apple seeds, which bring about five dollars a bushel. From 100 to 200 bushels of apple seeds are frequently sown by single firms in America, producing millions of "stocks," which are sold two to six dollars a thousand. These stocks are grafted by men and boys in the winter season, packed in sand or sawdust in cellars, planted in nurseries in spring, and after two summers' growth are sold from 50 to 200 dollars a thousand.

It has frequently been insinuated by British protectionists that American apples are poisonous, and should at least be either pared or carefully wiped, in consequence of their having, while growing, been saturated with *London Purple* or *Paris Green*, which are used to fight the Codlin moth; but this danger may be dismissed as mythical. It is true that most of the trees and fruit are sprayed with these poisons, but it is while the apples are very small, and every trace of arsenic is washed away during the three or four months before gathering. It is true, also, that a short time ago large quantities of apples were seized by the New York Board of Health and destroyed on the testimony of some health officers that they were poisonous and dangerous to eat, owing to above practice of spraying the trees; but repeated chemical analyses, both before and since, have failed to detect any poison on the edible fruit when gathered for the market. Moreover, the Americans eat apples in profusion, and millions of barrels have come to this country (say half a million barrels every year), but who ever heard of anyone being poisoned by apples!

Greater uniformity in packing is highly desirable, and when the farmers

find out that the manner of packing greatly influences prices they will take more care than they usually do. A neatly-packed barrel of apples brings 4/- to 8/- more than one into which the apples have been thrown without any effort to make a good show. The best way is when you begin to pack, turn the barrel upside down, the head resting on the ground or floor, then take the bottom out, but leave the head in, and cover it with a piece of thin paper. Then choose about a peck of the prettiest and finest apples, wipe them clean, being certain that there are no spots on them, or in any way disfigured, then place them in the barrel with their stems down, first placing them around the rim of the barrel, entirely round the same, after which make another ring, until the whole is covered. Then pour in more apples, and when the barrel is full, press the bottom on as already shown, and finally turn the barrel head upwards. When such a barrel is opened from the top, the apples will be found in good condition, even and nicely packed.

The freight from Boston to Liverpool varies from 1/6 to 2/- a barrel, but from Halifax, Canada, it is 3/-. A barrel of American apples (2¼ bushels) should contain about 150lb. The American and Canadian barrel is about one-tenth larger than that known as the Nova Scotian. This latter province exports about 500,000 barrels a year, and they are mostly from the Annapolis Valley (see also *Canadian produce*). They keep best closed up in the barrel at a temperature of about 30°. They should not be exposed to frost, unless very slightly. When opened they rapidly deteriorate. If they sound loose in the barrel it is a sure sign they are in bad order.

American Bacon, Hams, etc. —(See also *Pork.*)

These arrive in large boxes, weighing 500 to 750 pounds each, packed with either salt or borax, and with the weights and contents marked outside.

Cincinnati used to lead in the slaughter of pigs, but now Chicago, killing some six million a year, is far in advance. The total killed in the United States is about fifty millions yearly. American bacon, being maize fed, contains a much larger percentage of water than English, and loses about 50 per cent. in cooking, while English only loses 25 per cent., but for all that England takes above half the American export, and receives about 200,000 tons a year from that country. The average size of the hogs slaughtered is about 230lb. Nine-tenths of it is now "borax cured," after being cut up into sides, hams, square shoulders, about 14lb. each, and clear bellies, 13lb. to 16lb. each. It is first cured mildly with salt and saltpetre, and then before shipment is liberally sprinkled with borax or other bore preparations. These latter will restore meat already in course of decomposition to a fresher appearance, but which, if eaten freely, may endanger the consumer's health. On arrival in this country the meat is taken from the boxes, washed, wiped, partially dried, and again dusted with borax, pea flour, or oatmeal. Sometimes it is slightly smoked, and some rubbed with "liquid smoke," to make it appear something like well-seasoned English bacon, but the boracic acid seems to permeate the whole, gives it a soapy appearance, and spoils the flavour. "*Boneless Ham Butts*," also "*Loins*," are now arriving as chilled pork in increasing lots from Boston, packed in cases of about 50lb. When dressed and cooked carefully they have proved very saleable. (See *Pork.*)

The names given to the various cuts are somewhat misleading. The "Wiltshire," "Cumberland," "Preston," "Staffordshire," "Yorkshire," titles merely refer to the *style of cut*, and should not represent the products to be those of the English counties named. Unfortunately, these cuts after arrival are sometimes dried, smoked, or rolled, and labelled so as to deceive the consumer, but the Legislature is trying to stop the system.

Shrinkage in Washing, Drying, and Selling American Bacon and Hams.

Provision dealers will appreciate the following excellent observations of Mr. R. Rutherford, President of the Liverpool and District Grocers' and Provision Dealers' Association, on American bacon calculations:—"In arriving at the loss on Borax or Salt-packed Meats," says Mr. Rutherford, "there are several factors to be considered. For instance, Square Shoulders and Long Cut Hams do not lose so much as New York Shoulders and American Cut Hams, which are pickled cured meats. From careful observations of different packers' goods, taken at various seasons of the year, the average shrinkage in drying (after hanging a week), ranges from 7 lbs. to 10 lbs. per cwt., according to the season of the year and the cure of the goods.

"Bellies and Shoulders lose rather more in drying than Bacon and Hams. It should be particularly noted that this calculation is based upon 7 days' drying only; should the goods continue hanging longer, they will lose, on an average, 3 lbs. to 5 lbs. per week per cwt.; but it is very injudicious to keep American provisions hanging longer than a week, because the depreciation in quality after that time is very marked, especially in borax-packed goods.

"Retailers often calculate the drying of hams and bacon in a rule-of-thumb way, reckoning that "a farthing a pound will dry bacon," and on this basis they estimate their profits. Upon reflection, it is obvious that if it takes a farthing a pound to dry bacon at 28s. per cwt., it must necessarily cost two farthings to dry it at 56s., the loss being calculated on the pounds of meat LOST IN THE DRYING.

"For instance, if a cwt. at 28s. loses 9lbs., which at 3d. per lb. is equivalent to 2s. 3d. in money, 9 lbs. loss at 56s. amounts to 4s. 6d.

"Another error frequently made in these calculations is that of adding the loss in shrinkage to the cost of a complete cwt., instead of adding it to the cost of the weight which REMAINS AFTER DRYING. If a cwt. of bacon costing 56s. in the box loses 10 lbs. in drying, the 102 lbs. left will cost 56s., consequently on this basis the cost of the cwt. would be 61s. 6d., not 61s. The absurdity of a retailer being at all times armed with a book of formulas and tables is admitted, but, if for convenience, it be necessary to adopt a rough-and-ready method, by all means allow the fraction to lean to the safe side, and add a halfpenny per pound to the price of all American meats costing in the box below 56s. per cwt., if sold within 7 days. It is extremely difficult, considering the various and fluctuating prices, to illustrate how the profit on Bacon, Hams, and Shoulders may be calculated with any degree of certainty. A good plan is to keep in mind a few safe rules and axioms as a basis for calculating the minimum profit that will avoid a loss.

"The following, among others, may be found helpful:—First, ascertain the DRY cost of the Bacon, Hams, etc., then add a seventh of the cost, and let this be the minimum price you must receive for the whole, getting as much more, of course, as the circumstances of your particular trade will admit. For instance, if the dry cost of a side of Cumberland Cut be 5¼d. per lb., a seventh added will bring the price to about 6d. per lb. This would be exactly 12½ per cent. on the turnover, which would in most cases show a net profit of 2½ per cent., calculating the average working expenses in a provision shop at 10 per cent. on the turnover. Considering the losses arising from waste, overweights, etc., connected with the bacon trade in shops where there is much slicing, or where small cuts are sold, this is the smallest profit that should under any circumstances be tolerated.

"If competition be so keen that such a minimum profit cannot be

realised, then either cease selling bacon or give up the shop, because such business can only result in loss, —possibly disaster!

"To illustrate the seriousness of not carefully noting the loss in drying, if eleven boxes of bacon, weighing 5,500 pounds, be hung up for 7 days, and then re-weighed, it will be found that about 500 lbs., which would represent one complete box, have been lost in shrinkage.

"In rolled bacon the loss is proportionately more startling, for out of five boxes the loss in drying and boning would represent about one box."

ROLLED BACON.—"The loss in rolling and drying bacon," continues Mr. Rutherford, "varies according to the weather and the cure. The average loss from boning is 10 lbs. to 12 lbs. per cwt., drying 7 lbs. to 10 lbs. per cwt. Taking the mean of these calculations and estimating the loss at 20 lbs. per cwt., or calculating 92 lbs. when rolled at the box cost of 112 lbs., it works out as follows:—

Rolled and Dried.

Bacon costing in the Box—

30s. 6d.	" L. T." will cost	4d.	per lb.
34s. 6d.	"	4½d.	"
40s.	"	5¼d.	"
44s.	"	5¾d.	"
48s.	"	6¼d.	"
51s. 9d.	"	6¾d.	"
55s. 6d.	"	7¼d.	"
59s. 6d.	"	7¾d.	"
63s. 3d.	"	8¼d.	"

In the above no account has been taken of labour and twine, as they stand against the value of the bones.

"A simple way to quickly ascertain the cost of dry rolled bacon is to add 1-5th on to the cost of the box price. This will be found near enough for ordinary practical purposes.

"Smoked bacon costs 1s. 6d. per cwt. over dry price.

"C.I.F." terms is approximately 1s. 6d. on 50s. per cwt. over "L.T." or Liverpool terms-

"Box weights" is approximately 1s. on 50s. per cwt. over "L.T."

"The above calculations are based on a 4 per cent. Bank Rate and the maximum loss of 2 per cent."

Borax-cured, or rather borax-packed, bacon and hams have come much into vogue. Sometimes a pickle made of salt, borax, sugar, saltpetre and water is forced into the meat by a pump; sometimes the brine contains no borax, but borax is dusted over the bacon afterwards, and it should be remembered that borax only helps to preserve the meat after it has been cured with salt or brine, and that although it keeps the meat from becoming too salty, it is not so reliable, and will not keep so long as salt-packed.

The use of borax is, however, now general among American packers, and is applied at the rate of about 7lb. to a box of bacon. The meat can be cured and sold much sooner when borax is employed, but as it gives it a soapy appearance, it should be washed off with tepid water before retailing.

A very useful illustration of the various American Ham and Bacon Cuts is published (price 6d. or 7d.) at the office of *The Grocer*, Eastcheap Buildings, London.

Special Importers—George Wall & Co., Ltd., Liverpool and Manchester, Special Agents for the "Runic," "Wallflower," and "Walnut" brands. (See advt., p. 10.)

American Cheese.—The chief American cheese States are, in the order of their importance:—New York, Wisconsin, Ohio, Illinois, Vermont, Iowa, Pensylvania, and Michigan.

The State of New York turns out half the total, and the production of this State with that of Wisconsin represents more than two-thirds of the total.

New York make is the best, and Wisconsin is fair, but inferior. Ohio cheese is often branded as Wisconsin, and cheese from both these and other States as New York.

The cheese made yearly requires the milk of about a million cows, and the export is 60 to 80 million pounds.

Ever since the factory system has been in operation large quantities of superior quality have been exported to the United Kingdom, and these compare favourably with our best.

The average weight of red is 63lb., and white 69lb. each, and the composition of the better makes shows water 22·59 per cent.; casein and albumen, 37·20; fat, 35·41; and ash, 4·80.

The earlier importations, even at their best, were rank, steepy, soapy, and scarcely fit to eat, but now American cheese is generally of excellent quality, more regular and uniform in size than English cheese, also clean-looking.

It is, in fact, the chief foreign opponent of the British producer, is largely consumed by all classes, and has acquired that position by the active study of principles reduced to practice in the system of manufacture

The Americans owe their system chiefly to the teachings of Mr. Joseph Harding, of Marlsbury, a pioneer in dairy education, and especially of that type of cheese known as the Cheddar. His method was to set the milk at a temperature of 80° F in a milk tub which could be artificially heated. As soon as the curd broke, it and the whey were raised to 95° or 100° F, which hardened the curd and separated the whey. During the heating the curd was stirred by a blunt instrument, and when this was over, the whey was separated while sweet. The curd was then allowed to stand, to develop acid, and when drained from the whey and cooled, was broken and ground. Whilst being ground, it was mixed with salt, 1lb. to every 36 gallons of milk. The cheese was then put in a press, and in a day or two bandaged. Mr. Harding observed that new made Cheddars gave out moisture at the rate of 2lb. per ton every 24 hours, and he used this fact to hasten or retard evaporation in the curing-room, when the temperature was lower or higher. By thus regulating artificial temperature, he could produce the finest quality of Cheddar cheese ever made, and being at all times willing and anxious to impart his knowledge, his system was speedily copied in America. The first shipment made from U.S. was in 1831, and from Canada, 1851.

An inferior quality, however, of American cheese, known in commerce as *Cheesine*, is often imported made up of either lard, cotton-seed oils, or oleomargarine. A sort of artificial milk is said to be first made by shaking up "bosch butter" or animal fat with warm skim milk, and the cheese is then made in the ordinary way. It is of good flavour, and doubtless quite wholesome, but to sell it as ordinary cheese is to cheat; the cream having been removed and sold for other purposes.

June Cheese—"Late June Cheese"—is that produced from pure grass milk, and is also termed "full cream" cheese. "Early June cheese" often includes fodder-made cheese.

"*Filled Cheese*" is a term applied to cheese filled with a compound of lard, cotton-seed oil, stale butter, or other fats, usually surrounded by a shell or outer casing of genuine milk cheese, and has chiefly emanated from Ohio, Illinois, and Wisconsin. (See *Margarine Cheese.*)

September Cheese, being made from well-seasoned grass, will keep the year round, and so commands higher prices than June make. Unfortunately, there are parties who keep June cheese in cold storage below zero till September, and then sell it as September make. Such cheese matures very speedily on the change of temperature and will not keep long.

During the last ten years United States cheese has fallen much out of favour on account of the practices above referred to, and the extent to which base imitations of popular European varieties is carried on in that country. The manufacturers, however, assert that such counterfeits are merely "*made to order.*"

English cheese factors have their agents in America, who select their cheese from different factories. These selections are usually collected at a central warehouse, and there the special mark or brand is put on, so as to do away with all risk of the dealers or consumer in England learning at what factory or district the cheese is made. The importer, and not the manufacturer, thus becomes known.

Latterly it has been strongly suspected that much of the Canadian cheese exported to England is really from the United States, and is only sent via Canada to deceive.

Cheese shipments from Canada and the U.S. during year ending:—

April	30, 1895	3,201,000	Boxes.
,,	30, 1896	2,766,800	,,
,,	30, 1897	2,869,491	,,
,,	30, 1898	3,443,519	,,
,,	30, 1899	2,875,997	,,

Calculated in boxes of 70lb. each.

American Crackers.—Also known as *Soda Crackers* and *Extra Toast Biscuits.*

This kind of biscuit, now so popular both there and here in such numerous varieties and imitations, was first made in the United States by Mr. G. Wilson, of Philadelphia. They appear to be made of flour and water, with a little salt, bicarbonate of soda (say one or two drachms to each pound of flour), and cream of tartar, worked into a stiff dough, rolled thin and then cut into squares.

These biscuits have a peculiar glassy fracture, and seem to require a proper cracker oven. To give any detailed formula here might lead to disappointment and loss.

Missouri flour, however, is said to be the best for crackers, and indeed for most kinds of biscuits. The best flour for this business is made at the Conemill, St. Genevieve, Mo. The peculiar limestone rock of that district is said to impart peculiar properties to the wheat, and it is eagerly sought for by biscuit makers.

Amfuhr.—A second quality of Moselle wine, produced at Burg, on the Rhine.

Ammerschwir.—A rich and luscious straw-coloured wine, produced on the Upper Rhine.

Amontillado Wine (*a-mon-til-yah-do*).—One of the finest and dryest sorts of three-year-old Sherry wine. It has a very bitter taste, and the peculiarity

of its flavour is a mystery of nature not yet understood. It is light in body and colour, rather than dark and rich, but contains more solids and sugar than *Montillo*, and is spoilt if brandy be added to it. Amontillados and the other "Finos," while young, breed more *flor de vino* (cream of tartar) than any other types of sherry.

Ammonia (Carbonate of). — F. *Ammoniaque;* G. *Ammoniak;* It *Ammoniaca;* Sp. *Amoniaco.*

A semi-transparent, fibrous mass, having the pungent odour of ammonia, itself a transparent gas, formed by the union of one part of nitrogen and three parts of oxygen.

The carbonate is used largely by pastrycooks in making light puff pastry, and as it is entirely dissipated during the baking, no ill effect can arise from its use.

It is also used for smelling salts, and called *Sal Volatile.*

Household Ammonia is easily made by dissolving, say, 2 oz. yellow soap in three pints of warm water. Then add 1 oz. pearlashes, and when nearly cold add 5 fluid ounces of strong solution of ammonia. Keep it well corked.

A solution of *phosphate of ammonia*, obtained by mixing a pint of water with about 3 ozs. of phosphate, is said to be the safest way of protecting clothing, curtains, and other fabrics against fire, by steeping them in it, after washing, starching, etc.

Liquid Ammonia is also now prepared for bath and other household uses, and sold in bottles.

Amomi or **Ammi Seeds.**—Dan. *Amomfris;* Du. *Amomizad;* F. *Amomes;* Ger. *Amömlein;* Sp. *Amomo.*

These brown grains or seeds are from the fruit of a genus of plants of the natural order of *Scitamineæ*, flourishing in the East Indies. They are identical with Malaguetta Pepper, the latter name being that given in the 13th century to the seeds exported from Tripoli. The plant bears a kind of pod or berry resembling a grape, and this encloses the seeds, which are about the size of chick peas. They have a hot aromatic taste like cinnamon, cloves, or pepper, and when good are light-coloured, heavy, and well filled.

Several species of this order yield the Cardomoms and Grains of Paradise of commerce.

Amoy Teas.—Grown in Fokien tea district on the east of China, which used to be the greatest tea country in the world. The trade in these teas has, however, been decreasing several years of late, and instead of exporting some 500,000 half-chests a year, the production scarcely reaches one-tenth.

The cause is attributed to vile adulteration with other leaves, sweepings, and dirt resorted to by the growers in order to meet the demands of money lenders and merchants who advance them money on usurious terms.

Anchovies. —Da. *Anchovis;* Du. and Sw. *Ansjovis;* F. *Anchois;* Ger. *Anchojin, Anschoven;* It. *Sardon Acciughes;* Sp. and Port. *Anchovas;* Sw. *Anjovis.*

The anchovy is a small but delicious bony fish, variously named *Brevorted menhaden, Alosa menhaden,* and *Engraulus encrasicholus*, four to six inches long, resembling the sprat, pilchard, and sardine. The anchovy in spring abounds in the Mediterranean, and the finest are caught off the island of Gorgona, near Leghorn, in May, June, and July. The fish are attracted to the boats at night by lighted torches, and are scooped up in seine nets. They are afterwards gutted and decapitated (the head and liver being exceedingly bitter), and packed with rock salt in small kegs weighing about 5lbs. each, gross as nett, also in alternate layers of salt and fish in larger casks, which latter after arrival in this country are opened and the anchovies filled with brine, coloured with Prussian red, and put into smaller bottles to retail at 6d. or 1/- each.

Anchovies are also packed in oil, after being cured in salt, besides being made into pastes, essences, sauces, etc. These fish are often cooked for the table by boning and frying in oil or butter, seasoned with cayenne, and served on toast, or they may be laid on thin strips

of brown bread and butter. They are also often eaten raw, the small fish being generally selected. "*Appetit Sild*" is a Norwegian term for Boned Anchovies. Inferior fish, such as sprats, pilchards, and sardines, are often sold for anchovies, especially in Norway, where sprats are regularly treated as anchovies, although excellent qualities of real anchovies also arrive from both Norway and Sweden, usually flavoured with cumin.

The *Sauclet du Languedoc* and the *Cabassous de Provence* are also varieties of the same family, and are frequently put up and sold as Anchovies.

The Americans preserve a species of anchovies, which they call "*moss bunkers*," in oil, like French sardines.

The genuine anchovy may be easily distinguished by its large silvery scales, the pink salmon colour of its flesh, the head is sharp-pointed, the snout of its upper jaw extends considerably beyond its lower jaw, its body is thin, and its mouth is large, the back is round, not sharp, and has a bluish-brown colour, the tail is widely forked and slender, *the ventral fin is much nearer the head than the dorsal one*, and this is the best test of all.

Anchovy Butter.—Generally made by mixing one part of anchovies, boned and beaten to a paste, and two parts of ordinary butter, with a little spice as flavouring.

Large quantities of anchovies are shipped to this country from Lisbon in barrels of about 1 cwt. each, and are usually sold by weight, gross for nett.

Anchovy Essence. — The unadulterated article is of a dirty brown colour, and the reverse of the bright-looking red preparation usually met with. The brilliant appearance is entirely owing to the addition of *bole armenian* or other artificial colouring matter. Bole armenian is, however, a fairly innocent medium, and 1lb. will sufficiently colour a thousand pounds of essence, but as much as 10lbs. and even 15lbs. of common red earth, venetian red, and chalk have been added by unscrupulous and cheap makers. When pure, anchovy essence possesses a very fine flavour, but the fish should be kept about two years to ripen. A good essence may be made as follows:—Pound the anchovies, boil the bones, etc., in a small quantity of water, add the fish to the strained liquor, with salt, pepper, and flour. Colour, if desired, may be improved with powdered annatto or infusion of cochineal.

Special firms—Charles Cocks & Co., Reading, Berks.; Osborn & Co., wholesale manufacturers, Newington Green, London, N.

Anchovy Paste. — F. *Pâté d'Anchois.*

Prepared by cleaning, boning, and drying the fish, then pounding it and rubbing it through a sieve to remove any pieces of bone and everything of a gritty nature, seasoning with salt and pepper. It is usually potted and covered with pure melted butter to exclude the air, or the lid may be fastened down with plaster of Paris or by other means. Anchovy paste is used as a relish; if kept long it should be stored in the dark and closed from the air to preserve its freshness and colour.

Most makers introduce lard and a little flour or meal to give it consistency and to increase the bulk. The most harmless colouring is a little cochineal or bole armenian, which latter, although a natural earth, is much less objectionable than other vivid substances often employed.

A Speciality:—C. Osborn & Co. beg to call attention to their *Pâté d'Anchois*, a la Francaise, as being the finest article introduced under the name of Anchovy Paste for Export. (See Adv. p. 4.)

Anchovy Sauce. — F. *Sauce d'Anchois;* Ger. *Sardellen Sauce.*

The anchovy was the basis of the old Roman sauces, then called "Garum," but most of the so-called anchovy sauces of to-day are made from cheaper fish, and only the best firms make the genuine.

Marine zoologists in this country have been devoting much attention to the anchovy, and an investigation by the Marine Biological Institution at Plymouth is likely to lead to the establishment, or rather re-establishment, of a regular anchovy fishery on our Southern coasts.

There seems no reason why an attempt this way should not be made, since the fish is known to be a denizen of British waters, and is always to be found in certain districts at regular seasons of the year.

Angelica or **Archangelica.**—F. *Angélique;* Ger. *Angelkraut, angelikawurzel.*

A candied or crystallised sweetmeat, prepared from the stalks of the large and umbelliferous plant, *Archangelica officinalis,* found on the banks of rivers and wet ditches throughout Northern Europe. Some varieties are cultivated in swampy situations near London, but that grown in France is by far the best. Medicinally it is considered a valuable stimulant, anti-pestilential, and agreeable stomachic.

The upper green stalks and stems are cut into lengths, boiled in sugar, and then dried or candied in much the same way as candied peels. The French preservers display considerable artistic taste in forming the pliant strips into knots, fishes, and various other ornaments. They are very delicious, and often employed as a green decoration for cakes, etc.

The fresh roots also are fragrant, slightly bitter, pungent, and sweetish, forming agreeable aromatic sweetmeats. To preserve these roots they should be well dried and kept in closely-stoppered bottles. In olden times various fancy cordials and aromatic tonics were prepared from them.

In Norway the roots are sometimes used as bread, and in Lapland and Iceland the leaf stalks are eaten with butter and salt-like celery. Indeed, the two plants possess many of the same characteristics.

One species indigenous to British Honduras, and St. Helena, known as *Sium Helenium,* grows 6 or 8 feet high, and much resembles celery. The inner parts of the stem are commonly eaten raw by the natives, and are of a tender succulent quality. It is marketed in short tubes, much like bamboo stems, and is sold under the name of "Jellico."

Angelica juice is also used in the manufacture of gins and bitters, and it is the prevailing flavour in *Benedictine.* (Many fatal accidents occur from persons using the poisonous *hemlock,* which should be known by its round, smooth stems, with purple or black spots, and its dark green and shiny leaves, which when rubbed have a nasty mousy smell, not unlike the urine of cats.) Angelica is usually sold in a green state by herbalists in summer.

The Wild Angelica (*A. sylvestris*) is sometimes substituted for the true cultivated variety, but is much inferior both in taste and colour.

The French growth, extensively preserved at Niort, Deux-Sevres, and Clermont-Ferrand, is much larger, thicker, and more fleshy than the English, besides which the flavour is softer and pleasanter. The best is in tubular stalks about eighteen inches long, two inches in diameter, the succulent flesh in the tube being about a quarter of an inch thick, and will keep perfectly sound and good for several years.

Débris d'Angélique is sold at about half price of best.

Angola Coffee.—This comes from the Portuguese colony of that name. Not being systematically cultivated, there is no definite type, but it is usually of medium size, concave in form, light brown in colour, strong and pungent in flavour, but somewhat rough, and without much aroma.

Angostura Bitters. — Angostura Bark or Cusparia Bark is the aromatic and bitter bark of the plant *Galipea cusparia,* a native of Venezuela, and derives its name from the city of Angostura, now called Ciudad Bolivard. "Cusparia" is the vernacular name for the same species of bark in New Granada. This bark is exceedingly bitter, and the odour musty and disagreeable, but is very valuable as a febrifuge.

Angostura Bitters, as a liqueur, now made in Trinidad by Siegert, but originally at Angostura, contain, or should contain, the extract of angostura (*canella cinchona*), lemon peel and other aromatics. It is a valuable tonic in dyspepsia, dysentery, and diarrhœa, but

in 1804 a kind of false bark, containing strychnine, was imported, and led to serious results, and its reputation suffered accordingly.

Angostura Coffee. — A large, flabby, yellowish bean variety, shapely in form, but light and chaffy in substance, and always "quakery" when roasted, the liquor being thin and almost flavourless.

Aniline Dyes, or Coal Tar Colours. — F. *Couleurs d'aniline;* G. *Anilin-Farben;* It. *Colori d'anilina;* Sp. *Colores de anilina.*

The word aniline is from *anil*, the indigo plant, but these colours are distilled from various organic bodies, amongst others indigo, but now chiefly from benzole, one of the constituents of coal tar.

Aniline was originally produced from indigo by Uverdorben, a German chemist, in 1834; and in the same year another German, Runge, extracted it from coal tar; but it was not until 1856 that it was manufactured in quantity by Perkin, and three years later Verguin, a Frenchman, produced aniline-red (Magenta). After that followed dyes and colours innumerable—violet, blue, orange, yellow, green, black, etc., usually by the combination of the products of tar oil or of their constituents, the pure and brilliant shades of which have largely displaced the dyes formerly extracted from woods and other vegetable substances.

These beautiful and most effective stains or dyes, of which there are at least 254 distinct colours, with different names, are chiefly made in Germany, that country beating the whole world in price and quality. They are obtained by chemical combinations with tar, producing very brilliant results and particularly on textile fabrics; but whether in the form of liquids, powders, or crystals, should never be used in foods or beverages. Many of them may be comparatively harmless substances, but some are decidedly poisonous. Seven of them possess marked poisonous qualities, of these five are yellow or orange, and two are green. Their names are: (1) Martin's Yellow, known also as Naphthalene Yellow and Manchester Yellow; (2) Dinitrocresol, or Saffron Substitute; (3) Picric Acid; (4) Metanil Yellow; (5) Orange II., or Beta Naphthol Orange. To these may be added Aurantia, which is classed as suspicious. The two green poisonous colours are (1) Dinitroso-resorcinol, and (2) Naphthol Green B.

Syrup of Violets is often adulterated with or substituted by these artificial dyes. They are often employed by unscrupulous manufacturers of cheap jams, confectionery, butter, etc., whose only care is to please the eye, regardless of their pernicious effects on delicate people and young children, but the late Mr. Bell, Chemist to the Inland Revenue Laboratory, has declared their use to be both an adulteration and a very deleterious one.

Aniline powders should always be dissolved by pouring hot water over them, and stirring thoroughly. They should never be boiled. The solution is more effective if used before becoming quite cold.

Special Firm—M. E. Holdsworth, 3 Norfolk Street, Bradford.

Aniseed. —Da., Por., and Sw. *Anis;* Du. *Anijs;* F., Ger., and Sp. *Anis;* It. *Anice;* Mal. *Adis-manis.* (See also *Badian, Star Anise,* etc.)

The small, oblong, and aromatic seed of an umbelliferous plant, like fennel, called *Pimpinella anisum*, largely cultivated in Russia, Germany, China, Malta, and Spain, the Chinese being considered far the best. It has been tried in England, but our summer is not warm enough to bring it to perfection.

The seed, about the size of a pin's head, contains a bluish volatile oil, known as *Oil of Aniseed.* It is used medicinally as a carminative, warms the stomach, and relieves flatulency, particularly in infants. Aniseed also forms a well-known balsam, an aromatic flavouring adjunct for sweets and cordial liqueurs, and it is used to neutralise nasty tastes in drugs.

Water flavoured with aniseed oil and sweetened makes a cooling stimulant

much used in Italy. It is also used largely at Bordeaux and Amsterdam in the manufacture of Liqueurs.

This seed should be fresh, large, plump, colour greyish green, with a good smell and of sweetish spicy taste. It is very similar in external appearance to the poisonous hemlock seed which has occasionally been mistaken for aniseed.

There are several species of anise, viz., the Bitter or False Anise, commonly called *Cumin*, the Bastard Anise or *Carvic*, the Sweet Anise or *Schinus*, the French Anise or *Fennel*, and the Star Anise or *Badian*.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

Aniseed Cordial.—A thin French liqueur of weak spirit flavoured with coriander and sweet fennel-seed in addition to aniseed, and sweetened with clarified white sugar.

Anise Fruit or **Badian.**—This is a different thing to *aniseed*, and is the tanned and shining fruit or seed enclosed within the very hard and very thick little pods of an East Indian tree (*Illicium anisatum*). It is used for flavouring tea, liqueurs etc. The grey timber logs known as *anise wood* (so called on account of its scent) are largely used for turnery ware and inlaid work.

A pale yellow oil with the odour of the fruit and of aromatic sweetish taste is distilled in Europe from this fruit, but the best badian comes from China.

Anise Oil. — There are two sorts, one from the anise fruit (*Pimpinella anisum*) and one (*Ol badianæ*) obtained in China from the Star anise (*Illicium anisatum*).

Anisette (*an-iz-et'*) is the name given to a stronger, sweeter, and thicker compound liqueur than *Aniseed Cordial*, and is highly condensed. The seeds of the common anise, star anise or badian, umber, fennel, coriander, all enter into its composition, with cinnamon, nutmeg, etc., as flavouring. It is of rather sickly flavour, and although said to be very serviceable in warming the stomach and relieving flatulency, it is not so much esteemed as a dinner liqueur, but more as a medicine for children. The Dutch make is strongest, and contains the least sugar. It is retailed at about 4/6 a bottle.

Anisette de Bordeaux is a liqueur made in France by distilling fennel, anise, and coriander seeds. It is then fortified with brandy and sweetened with syrup.

The most popular in France is that of Marie Brizard (Bordeaux), which claims to be made according to the recipe of an old woman who lived there about two centuries ago.

Annatto (also spelt Anatto, Arnatto, and Annotto).—F. *Rocou;* Ger. and Rus. *Orlean;* It. *Ariana;* Port. *Oriana;* Sp. *Achiote;* Sw. *Orleana.*

A bright orange-red dye or colouring substance obtained from the pulp found in the seed-pod or capsule of the Arnotto tree, *Bixa orellana* of Linnæus, an evergreen shrub eight or ten feet high, and sometimes growing to some twenty feet high, bushy from the root and forming a single stem, very common in Ceylon, tropical America, Jamaica, and other parts of the West Indies, and has been successfully introduced into many tropical regions of the Old World, but it is chiefly prepared in Brazil and Cayenne. Its leaves are heart-shaped, dark green on upper side, and light green streaked with red veins on under side. Its flowers are either of a rich crimson colour or white, and grow at the end of the young branches in clusters. The fruit-pods also are heart-shaped, about an inch long, red coloured, and covered with stiff prickles, containing thirty to fifty small seeds like raisin stones, the seed, or *Achiote*, as it is called in America, being embedded in a reddish-yellow waxy pulp, which, after the pod is either rubbed or crushed in a tub of water, settles to the bottom. This sediment is then strained, boiled to a paste and dried to the stiffness of putty. In Cayenne, it is then formed into cakes or flags of bright yellow colour, firm and soft to the touch, and

weighing two or three pounds each, wrapped in banana leaves, and packed in casks for exportation. Sometimes the seeds, as taken from the pod, are gathered, simply dried, and exported in bags, especially from Jamaica. In Brazil, the paste is refined and made up into small rolls of 2 ozs. or 3 ozs. each, hard and brown outside, but of a beautiful yellow inside. The real colouring matter is a combination of *orellin* (yellow) and *bixin* (cinnabar red). It is not soluble in water, but is freely soluble in ether, alcohol, or volatile and fixed oils, giving them a brilliant orange colour. Alkaline solutions darken, and sulphuric acid turns it blue. Aniline colours are now used in place of annatto for many purposes.

Annatto, as met with in the English market, is generally mixed with carbonate and sulphate of lime, starch, flour, chalk, salt, red earths, turmeric, gypsum, or other cheap substances, but these must scarcely be termed adulterations, some mixture being requisite to adapt it to its various uses. Pure annatto should not contain more than six per cent. of ash. For quality the Ceylon product takes the lead. The organic adulterants may be easily detected by the microscope. Annattoes have been found adulterated with red lead, which is highly poisonous. Annatto is used largely by dyers, painters, varnish makers, and soap makers, and when good, forms the most popular colouring, odourless and tasteless, for butter, cheese (see *Edam cheese*), also for tingeing cream ices, etc.; ½ oz. to 1 oz. being sufficient for 1 cwt. cheese. The Spaniards put it in their chocolates and soups. *Liquid Annatto* or *Solution of Annatto* is easily made by boiling equal weights of flag annatto and pearl-ash with water, and diluting to the colour required. Some recommend 10 parts good annatto and 12 parts of pearl-ashes, with 78 parts of water. The South American Indians colour their bodies red with annatto. As a medicine it is slightly purgative and stomachic. London market prices for flag annatto vary from 4d. to 1/8 per lb.; seed, 3d. to 6d. per lb.

Anthracite (See also *Fuel*).—A black, brittle substance used as fuel. It occurs chiefly in transition formations between the strata of the clay-state and of the grey-wacke. It burns with a feebly luminous but smokeless flame, does not soften in the fire, but often crackles and decrepitates. It owes its superiority to other fuel to its cleanliness, hardness, and smokelessness. Used chiefly in lime-burning, brick-burning, also in salt works.

Anti-fat. — A widely advertised preparation, seems to be a fluid extract of the common seaweed, *Fucus vesiculosus*, known as sea-wrack, bladder-wrack, or lady's wreck. It is acknowledged to be very efficacious, owing either to the iodine the plant contains or to its gelatine neutralising the digestive fluids of other foods.

Anti-febrine.—A proprietary article lately introduced as the sovereignest thing for febrile affections.

It appears to consist of 75 per cent. of ordinary anti-febrine, 17·5 per cent. of bicarbonate of soda, and 7·5 per cent. of tartaric acid, but is offered at about six times the price of anti-febrine.

Anti-Ferment. —A useful preservative for cordials, etc. It is a strong aqueous solution of sodium salicylate, and contains a large proportion of acetic acid, but no boric acid.

Anti-Rust. — See *Vaseline*, *Polishes*, etc.

Antiseptics.—(From Latin, *anti*, against; *septos*, putrid; or *septikos*, putrescency).—A collective term for a crowd of preparations, simple and compound, which have the property of preventing or arresting the decomposition of foods, or of preventing fermentation and putrefaction. They do not entirely prevent decomposition, but rather permit stale goods to be made presentable. *Boric Acid*, *Formic Aldehyde*, or *Salicylic Acid*, *Alcohol*, *Sea Salt*, *Creosote*, and *Camphor* are all antiseptic. On the other hand, Disinfectants are supposed to destroy infecting spores. Antiseptics may, however, be considered to some extent as Disinfectants.

Of course there are many other Antiseptics, such as *Perchloride of Mercury*,

Carbolic Acid, *Chloride of Lime*, etc., but these, being exceedingly poisonous, are not to be admitted among food preservatives.

An objection to the use of Antiseptics is that they prevent the natural digestion of foods after they have entered the stomach, and refrigeration is considered the best method to adopt.

Anti-Sour.—A preparation for preserving aerated beverages and cordials. An ounce is sufficient for four gallons of syrup. Wholesale prices, 3/6 to 4/- per lb.

Antour or **Autour.**—A kind of bark brought from the Levant, resembling cinnamon in shape and colour, but is thicker and somewhat paler. It is used in preparing *Carmine*.

Ants' Eggs or **Ants' Brood.**—A natural and esteemed food for birds, poultry, fishes, etc. Price, in bales of 1 cwt., about 120/-.

Ants' Brood is an article of import in some of the northern countries, probably for making *formic acid;* dissolved in water, they serve the purpose of vinegar in Norway.

Apollinaris Water. — An alkaline and strongly effervescent mineral water derived from the Apollinaris Brunnen, a mineral spring in the valley of Ahr, in the Rhine province of Germany.

It is extremely rich in carbonic acid and very popular for table use.

The bottles and jars are all filled and sealed at the spring to prevent fraud.

Appalachian Tea. — Obtained in North America from the plants *Viburnum cassinodes* or *Prinos glaber*.

Apparatuses and Utensils of Trade. — See *Shop Fittings*.

Appetitsild. — A Norwegian preparation of boned and skinned anchovies put up in tins, wooden barrels, or kegs. It is not cooked or sterilised like salmon, lobster, or sardines, but is simply cured by salt and spices, much in the same way as herring or mackerel, and will keep good from season to season. Although generally packed in small tins, as being more convenient for table use, an air-tight package is not at all necessary. The blowing of the tins, so ominous in ordinary cooked foods, is, in the case of appetitsild, a good sign of ripeness.

Apples. — A. S. *Appel;* Dan. *Able;* Dut. *Appel;* F. *Pommes;* Ger. *Apfeln;* It. *Mele;* Port. *Maçaa;* Rus. *Gabloko;* Sp. *Manzanas;* Sw. *Aple;* W. *Afal*. (See also *American Apples*, *Green Fruits*, etc.)

The fruit of the *Pyrus malus*, or apple-tree, which is cultivated almost all over the temperate zone, succeeding best in the colder parts of that region.

Without going back to the calamities traditionally attributed to its first appearance in human history (for it is asserted that the apple of the Bible was really a *quince*), it may be stated that it reached Europe from the East, the mountains of Asia Minor, and it seems to have been distributed in Europe mainly by the Teutonic race. It was probably introduced into England by the Romans.

The small, wild, and sour crab, or austere apple is supposed to be the grandmother of all our English apples. The acid of apples is called *malic* acid.

There are some five thousand varieties and sub-varieties of apples, and these are increasing yearly. Dr. Hogg has attempted a scientific arrangement according to the structure of the stamens, tube, capels, and sepals. Apple-trees are propagated by seeds, layers, grafting, and budding. As a rule all rough-coated apples are good for eating and smooth ones for culinary purposes. The "black spots" seen on the outside of apples are due to the presence of a fungus, and impoverish the fruit. Early windfall apples, if exposed for sale in so immature a state as to be dangerous to health, are liable to seizure. In planting good varieties should be selected; also size, appearance, free-bearing quality, and good constitution. The trees should be planted in pyramid form and worked on a paradise stock. They require fertile soil and sheltered situations, although some varieties are more hardy than

others, and thrive best in cold or exposed situations.

The ordinary crop grown in Great Britain averages about 90,000 tons, and the value about £10 per ton. The best and earliest baking sorts are the *Calvilles, Codlings;* the best for autumn use are the *Rennets, Pearmains,* and *Greenings.* Perhaps the most profitable cooking varieties grown in England are the *Bismarck, Ecklinville, Dumelow's Seedling, Gascoyne's Scarlet, Golden Spire, Lord Suffield, Newton Wonder, Potts' Seedling, Tower of Glamis, Warner's King, Wellington, New Hawthorndean,* and *Lane's Prince Albert;* the latter being the longest keeper.

The best for table use are *Orange Pippins, Golden* and *Ribston Pippins, Russets, Duchess of Oldenburg* (an early variety), *Devonshire Quarrenden*—King of *Pippins* (nice and soft when fully ripe; flesh nearly white, but with yellowish tint), *Kempster Pippin* (an orange or red-streaked variety with yellow flesh), *Worcester Pearmain* (a bright red coloured variety with beautiful white flesh), *Wykin Pippins,* and *Court of Wick;* but *Ribston Pippins,* renowned for flavour, are unfortunately becoming extinct in England, owing to the disease called "canker." The *Cox's Orange Pippin,* of orange or red-streaked colour, has a sort of Ribston flavour, aromatic and vinous, with firm flesh, and very juicy. The *Calville Blanche* is of large size, shape flat or corrugated, with broad and uneven edges which end at apex of fruit. *Court Pendu Plat*—This is a very flat-looking apple.

Russets are of very superior flavour; but being mostly dull of colour, the public require educating to appreciate them.

It is a common practice in farmers' orchards to allow grass to grow around the young trees, but it has been proved that this practice reduces the amount of the growth of the trees to one-eighth of that usual where the soil is kept open. There are also lots of old orchards in this country filled with worn-out fruit trees, many of them varieties which are of no value, while there are plenty of splendid varieties to replace them, but which it seems nobody's interest to plant and cultivate. The best kind for boiling to pulp for jam-making are the *Wellingtons* or *Goffs.*

Of *crab-apples* those from Siberia are the best; they reach England during September and October.

Highly-coloured apples are ordinarily soft and woolly.

French apples are usually very nice and mellow to look at, but generally too sweet, pithy, insipid, and juiceless. The crop is about 1½ millions yearly, and average value about £5 a ton; and large quantities are used for cider.

In Japan a kind of dwarf apples, about the size of peas, are cultivated on trees growing only about four inches high. It is a mistake to believe the early bloomers are early ripeners. Those kinds that keep the longest ripen the last. Apples are said to keep best and longest if stored in a cold atmosphere, say 32°F., merely requiring to be kept from frost.

No straw, hay, paper, etc., should be used, for it is apt to turn moist and mouldy and impart mustiness.

A good plan is to store them in a dry airy cellar, packed in alternate layers, with clean dry sand, in barrels. They also keep well on latticed shelves in a dry cool atmosphere, and choice fruit should be laid singly. The fruit room should not be shut up too closely before the apples have become moderately dry. They are often spoiled on shipboard by heat. Perhaps the most careful way to pack dessert apples for inland travel is to wrap each in paper, and then nest them in dried moss or wood wool.

When apple trees are heavily cropped, a third or even half may be gathered and sent to early season markets, and bring good prices, and those left on the trees then grow much finer than if all had been left to ripen. All wind-fallen or bruised apples should be kept by themselves and marketed separately.

Kitchen apples should always be thrown into cold water as soon as peeled and cut, to keep them white. If they should become discoloured a little lemon juice will make them right again. Over two million barrels and cases of foreign

apples, costing about a million sterling, and mostly of excellent quality, are imported yearly, chiefly from United States (see *American Apples*), Canada, and Cape Colony; but also from France, Australia, and New Zealand.

Tasmanian apples (mostly *Ribstons, New York Pippins, Bismarcks, Sturmer Pippins,* and *Barmains*) arrive in bushel boxes, holding 36lbs. to 40lbs. each, and we now receive from one to two hundred thousand boxes of these juicy sorts at a time when other supplies are either scarce or comparatively inferior.

The success of the apple trade of the colony is largely due to Dr. Benjafield, who went thither about nine years ago, and is now a large grower and exporter.

Thirty years ago there were very few beyond those grown in England, except some fancy kinds from France, and some of very inferior quality from Holland and Germany; but soon after that time New York began to send Newtown pippins, followed by other varieties; a few years afterwards Canada followed, and then Nova Scotia, until the supply from these sources last winter was 1,217,767 barrels.

With the advent of cool chambers they are now successfully brought from California, Tasmania, and South Australia, so that we are never without a full supply of fresh ripe fruit. The Australian, ripening as they do at Christmas-time, are very acceptable here as other supplies get short. The quantity from these three centres, all coming in cool chambers, now exceeds 300,000 cases.

Notwithstanding these foreign and colonial importations, many English farmers and landowners are ever ready to contend that there is no profit in orchards. Others say it is a result of our land system, which makes it nobody's interest to plant and cultivate fruit trees in this country.

The four greatest fruit-producing counties are Devon, Hereford, Somerset, and Worcester. Devon has the largest acreage under orchards, but it has made little or no progress of late years, and there are hundreds of orchards a disgrace to those who own or rent them. Not only is the fruit gathered and packed without care, but it is sent to market without regard to season. Good-keeping apples that should not be marketed till April or May are sold at any price, and consumed in the autumn.

The apples imported in 1896 were 6,177,192 bushels; declared value, £1,582,471.

Canned apples also are imported in gallon cans, which are packed six or twelve in a wooden case. Costermongers owe their name to the vending of the old Costard or Custard apples. Apple-tree wood is hard and heavy, and is much used by turners—mostly for making shoe-lasts, weavers' shuttles, and in machinery. It lasts a long time if kept out of water.

In cooking apples the skin may be easily slipped off by first pouring scalding water on them. Apples will cook in boiling water at a temperature of 212°F., and will bake at 225°F.

Early kinds of apples are invariably best when eaten direct from the trees, as they soon lose their freshness; but late apples are the most profitable to growers and speculators.

Apples and Apple Rings (*Dried* or *Evaporated*).—F. *Pommes Tapées.*

Both whole and ringed evaporated or dried apples are coming more and more into general use, and with similar fruits may, in the early future, considerably curtail the raisin and currant trade.

The Americans have, during the last twenty years, become such adepts in the art as to be able to convert every pound of fruit into a marketable commodity (see also "*Canned Fruits*"); and this, to a certain extent, makes the grower independent of seasons, situations, glut of markets, etc., for if the prices for fresh fruit are too low he may set to and evaporate or dry it and keep it for better prices.

In the drying process the apples are first pared, and if intended for rings, cored and sliced, these operations being rapidly performed by a little machine named the "Electra." The apples are then placed in water in which a little salt has been dissolved so as to prevent discoloration. They are also submitted to

the fumes of sulphur for a short time to fix the colour.

The fruit is next placed on a wooden tray with a fine wire bottom, which, in turn, is fitted into the drying machine, just above the furnace, where it remains about five minutes. Another tray is then filled, and takes the place of the first, which is thus raised higher in the machine; and so the trays take the place of each other until four of them are fitted into the machine. As soon as the fruit is sufficiently desiccated, it is removed and placed to cool before being packed in the ordinary way. The time occupied in thus drying apples is from two to four hours.

Plums and certain other fruits are usually dried at three operations, but apples are best done at once.

They make capital tarts and puddings after being first washed and then soaked in clean boiling water with a little sugar for a short time before being used.

A vast quantity of these are prepared in America. In some cases it is the custom to sort the fruit, and sell the best in a fresh state, and only dry the inferior or damaged portion. The best are of light texture, and arrive in cases of 25lbs. and 50lbs. nett weight; carriage and freight to Liverpool about 1/3 per 50lbs. Prices, 30/- to 40/- per cwt. Those of brown colour are considered old and inferior, and average 20/- to 30/- per cwt. A bushel of green apples produces 30lbs. of meat and 20lbs. of parings, core and refuse, and will yield about 6lbs. of dried apples and 4lbs. of dried refuse. The latter is sold for jelly-making. There have been absurd reports about American dried apples being poisonous on account of being dried on zinc wire grates, by which process the acid of the apple comes in contact with the zinc, but the amount of zinc absorbed is exceedingly small, and any danger to health groundless, yet the sale of such fruit is not allowed in Germany. Over twenty million pounds of dried apples are now exported by the United States every year, and Canada has also entered the field with excellent results.

Apples are also dried in France, especially in Touraine, and sold under the name of "*Pommes tapées*," but large quantities are imported from America for cider making.

In the Rhine districts apples (and pears) are commonly cut in pieces and strung on pack thread. They are then hung up to dry, and serve as vegetables to eat with roast meat, or with pancakes through the winter.

With persons of sedentary occupations the use of fruit is becoming a recognised necessity, and the trade in evaporated apples is well worth the attention of all retailers in large towns, and particularly in the manufacturing districts where fruit trees are scarce. Care should, however, be taken to see that the fruit has been properly dried. Some of the dried apples are but imperfectly cured, the manufacturers evidently looking more to weight than to perfect drying. Such fruit is apt to go mouldy soon and become useless. Sometimes old stocks of dried apples are steamed to give them a fresh appearance, but this renders them liable to turn sour in a short time. (See also "*Evaporated Fruit.*")

Apple Butter is made in America, by boiling six gallons of cider down to *one*.

Apple Champagne. — See *Temperance Drinks.*

Apple Jelly.—Take 20lbs. strong apple pulp, 1 gallon of water, 1 oz. powdered citric acid. Put the pulp and water into the pan, and bring them to a sharp boil; turn the whole into flannel bags, and strain the whole of the juice through. Return the juice to the pan, and to each gallon add eight pounds of Dutch crushed sugar; stir them well until the sugar is melted; when the syrup boils remove any scum which rises with a skimmer; continue the boiling until the jelly hangs to the skimmer in thick flakes; cool, and fill into clear glass jars or bottles.

Much of the apple jelly sold in America is made from the cores and parings, mixed with glucose.

Apple Wine. — The best is made from the purest and best cider.

To every four gallons of cider add 10lbs. of sugar. Put these proportions into a clean cask till about three parts full; leave it in a cool cellar or other place for two days without a bung. Then bung it, but leave a small aperture so that the gas of the fermentation may escape. Immediately fermentation ceases drive in the bung and vent peg tightly. It should then remain a year in store undisturbed.

Most of the apple wine met with is not, however, of the above origin, but usually consists merely of aerated water and sugar flavoured with the fruit essence.

Apricots. — Da. and Sw. *Apricos;* F. *Abricots;* Ger. *Aprikosen;* It. *Albicoccos;* Port. *Damascos;* Sp. *Albaricoques.*

The old English word was "Apricock," from the Latin word *præcox*, or early ripe. They are the fruit of the *Prunus armeniaca*, an African tree fifteen to thirty feet high. About twenty varieties grow wild in India, and several of them are cultivated in the South of England (especially in Kent and Surrey, on standard trees), also in France, Italy, and Turkey. The flowers, pinkish-white, precede the leaves. The trees will grow almost anywhere, but the least frost in February or March will kill the flowers and destroy all chances of fruiting. The fruit, which nearly equals the peach, is roundish in form, downy, yellow, or orange-coloured, and ruddy on the side next to the sun, and the flesh is yellow, but has a stone like a plum, pointed at one end and perforated so as to admit a pin.

Apricots keep fresh only a very short time, and are seldom preserved in this country. They were first brought into Europe by Alexander the Great, and first grown in England by a priest named Worl, in the time of Henry VIII. The fruit is less acid than most stone fruits. For culinary purposes it is used both green and ripe, and preserved in both these states; also candied, when ripe; and sometimes dried as a sweetmeat. The kernels are valuable and very like sweet almonds. Apricots are extensively grown in Turkey, Italy, and France, whence they are exported both in a dried and candied state.

Clermont-Ferrand is noted for its conserves and compotes; of English growths, the finest are the *Moorpark* and the *Breda*, but in France the most popular are the *Nancy* and *Triel* varieties.

Immense quantities of apricots, £20,000 or £30,000 yearly, are grown in Damascus, and form one of the principal exports, either dried whole or in paste. A black pigment, similar to Indian-ink, is prepared from burnt apricot stones, and a large weight of these latter is exported from Syria to Europe every year. Ship-loads arrive at Marseilles, where they are ground to oil for soap making. *Apricot kernels* are also a marketable commodity, and fetch about 36/- per cwt. *Tinned apricots* in syrup mostly come from the United States, and especially from California, where this fruit grows to perfection. They are packed in 2½lb. cans, price about 11/- a doz.

Fresh apricots for market are usually gathered as soon as well coloured and before they get soft. They are carefully packed in small shallow boxes, just deep enough to hold one layer, and with the sides and ends lined with lace-edged paper, standing up about half an inch so as to fold over the fruit and form a fringe.

Paper shavings, wood wool, or dry, clean soft moss is used on the bottom to raise the fruits to an even level, and some blue or pink tissue-paper is placed between the moss and the fruit, so as to leave the upper surface bare when the box is opened, without disturbing the fruit. A sheet of clean white paper being placed over the fruit, the fringe turned down, and fitting evenly and tightly without crushing the fruit, the lid is affixed lightly with one, or at most two, tacks at each end.

Apricots for preserving should be evenly coloured, but not soft, when

gathered. Soft apricots travel badly, and only keep sound three or four days.

Apricot Jam, Marmalade, Pulp, etc. — The jam is now chiefly made from the tinned apricots or pulp from France, Spain, the Cape, Australia, and California. The former variety, particularly those grown in the neighbourhood of Bordeaux and in the valley of the Rhone, are considered of the finest flavour, but the Spanish varieties possess the richest colour. The gelatinous properties of each are about equal, so the quantity of sugar required for each is the same. A good jam is made of 20lbs. pulp, 15lbs. crushed sugar, and 8lbs. glucose, but if the apricots are very ripe no sugar is needed. Some makers use twice this quantity of glucose, and add a dozen pounds of apple pulp. The foreign fresh pulp is usually to be had in 10lb. tins, at about 20/- per cwt., from London dry fruit merchants. This re-boiled up and jarred sells well and profitably. The kernel or almond is usually taken from the fruit stone, skinned and split and added to the jam or marmalade.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Aqua Fortis. — A name in old chemistry for *Nitric Acid*.

Aqua Vitæ.—Literally the "Water of Life." A Latin term often applied to brandy, or a favourite ardent or unflavoured spirit of any kind. In Scotland it is whisky, in Ireland usquebaugh (whisky), in Holland geneva, in France *eau de vie* (brandy).

Aqua Vitæ was a term first given by the Genoese to the alcohol distilled from grain.

Arabian Tea.—Obtained in Arabia from the plant *Catha edulis*, natural order Celastraceæ. The name sometimes used for Abyssinian or Kaat tea, and occasionally for Algerian tea.

Arabic Gum or **Gum Acacia.**—Arab. *Samagh arabee;* Du. *Arabische gom;* F. *Gomme arabique;* G. *Arabische gummi;* It. and Port. *Gomma arabica.*

The name of the most valuable class of gums which contain *arabin* and exude spontaneously in a liquid state from various kinds of the Acacia tree, such as Kordofan, Turkey, Senegal, Talka, Cape Morocco, or Barbary. The world's supply may be said to come from the Soudan, the chief market being Khartoum. Taken on barges to Cairo in bales of 500lbs., it is shipped to London, Marseilles, New York, etc., to the extent of some 18,000 bales a year.

It hardens by exposure to the air, and is largely employed in medicines to hold in suspension insoluble drugs, also in giving lustre to crape and silks, and for making the best qualities of gumdrops, jujubes, etc.

The various gums known as Gum Arabic differ very much, and not only do the gums from different countries differ, but those from one country vary considerably according to the nature of the season. It is said the largest quantities are obtained in the hottest seasons and from sickly trees.

The best Arabic Gum is that obtained from the African *Acacia Vera*. It is of whitish yellow colour, transparent, very brittle, often cracked on the surface, and frequently met with in a broken or powdery condition, the result of its long land carriage in Egypt. No gum comes from Arabia now, so that all sorts of things nowadays are sold under the name of gum arabic, and it is growing more and more difficult to obtain the genuine free from adulteration. Dextrine is largely used as a "cheapener," and the powdered gum is frequently additioned with absolutely worthless substances. The price being a guide, the buyer should not feel hurt if he discovers that the so-called gum Arabic is an Australian gum resin closely resembling the real article, but the latest substitute carries the thing a little too far. It is said that a mixture of sugar candy, milk, and soda water-glass is sold in lumps and powder, and is a perfect imitation of gum Arabic.

Special Firms—M. E. Holdsworth, 3 Norfolk Street, Bradford; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Arachide or **Arachis Nuts.** — See *Ground Nuts.*

Arachis or **Ground Nut Oil.** — A fine bland oil, pale yellow or greenish yellow in colour, obtained from Arachis or Ground Nuts, which yield 20 to 40 per cent., equal in quality to olive oil—which indeed it often represents, and is also extensively used in soap-making. It has a faint nut-like odour and a bland nutty taste, specific gravity 0·916 to 0·918. It becomes turbid at 37·4°F., and solidifies at 23°F.

Large quantities are prepared at Marseilles, Bordeaux, and Nantes, also in London. But more is made in Germany than anywhere else, Hamburg, Mannheim, and Heibrunn turning out an immense amount.

New works for the expressure of this useful oil are being opened up in several other towns, Trieste, Antwerp, Liverpool, etc.

The nuts are first cleaned, then decorticated and winnowed. They are next crushed, put into bags, and subjected to cold pressure, and finally the expressed oil is refined by passing through filter bags. A bushel of nuts pressed cold will yield a gallon of almost colourless oil, and a second quality of darker, if heated. The prices vary from 19/- per cwt. for Madras pale to 44/- for Rufisque.—Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Arakan Rice (also spelt Aracan and Arracan).—A low-priced rice imported from the Arakan Hill range, a long and narrow strip of territory about 400 miles long by 15 to 80 wide, in Lower Burma, in the Bay of Bengal.

Araki. — An Egyptian liquor prepared from grapes. (See *Arrack.*)

Archangel Ox-Tongues. — Ox-tongues from Archangel, the chief commercial city and province in the North of Russia and Siberia, on the White Sea, which is only clear of ice in July, August, and September. Wholesale prices, 12/- to 18/- a dozen. In buying these tongues care should be taken that they are real ox-tongues—not tongues of old cows, horses, etc.

Archil. — See *Orchella Weed.*

Areca Nuts or **Betel Nuts.**— (See also *Betel.*)—F. *Noix d'arec.*

These are the fruit of a tall, straight, and slender species of palm tree, known as Pinang, and the *Areca catechu*, or Cabbage Palm, which grows thirty to forty feet high in Malabar, Straits Settlements, Philippines, Ceylon, and Sumatra, whence thousands of tons of the nuts are exported yearly to China and other countries. A single tree yields 200 to 800 nuts. In India it is said that 100 million people chew them every day.

The areca nut is of orange colour, pear or egg-shaped, about the size of a walnut, very hard and smooth outside, but rough and hairy inside; and the kernel is about as big as a nutmeg, to which it bears a strong resemblance inwardly as well as outwardly.

They are usually chewed by the natives after preparation with chalk or lime and the leaves of the Betel Pepper (*Piper betle*) hence often called *Betel Nuts.*

The fresh nuts have intoxicating properties, and produce giddiness; in fact, some trees possess these properties to an unusual extent, and even retain them when dry; but the red nuts of commerce have undergone a process of baking and heat which diminishes their intoxicating property. The charcoal is used as tooth-powder. Present value of the nuts on London market about 12/- to 20/- per cwt.

Arge Beer. — See *Beers.*

Argentina Cheese and Butter. —Argentina in South America is essentially a grazing country, but until about 20 years ago, cheese and butter of home manufacture were almost unknown there, and the inhabitants had to depend on foreign importations.

This is now partly changed, and the Republic has become an exporting country, to the extent (1896) of 490 tons of butter and 61 tons of cheese, and the business seems likely to extend rapidly.

The custom prevails in Argentina of allowing the calf to run with its mother in the open pastures, and cows require

to be tamed before they will submit to daily milking.

There are two large dairy farms milking 1,200 and 1,500 cows per day, besides receiving large quantities of milk from outside farms. They turn out ¾ to 1 ton of excellent butter per day, and employ steam milkers and the most improved apparatus and machinery. Eggs also can there be bought retail in November at 6d. and 7d. per dozen.

Argol (also spelt Orgal and Argall). —Du. *Wynsteen;* F. *Tartre;* G. *Weinstein;* It. *Spa;* Lat. *Potassium Bitartrate;* Port. *Tataro;* Rus. *Winnui kamen;* W. *Gwin-gên.*

A hard crust of unrefined or *Crude Tartar*, which forms on the insides of wine casks, vats, and bottles, from grape-juice, white, reddish, or greyish, according to the colour of the grapes. That obtained from white wine is *white argol*, and that from red wine is *red argol*. It consists of tartrate of lime, potass, and earthy matter. When dissolved, purified, and again deposited, it is called *Cream (or Crystals) of Tartar*. It is largely imported in thick, hard, shiny lumps from France, Spain, Portugal, and Italy, but the latter, and especially that coming from Bologna, is best.

Argol is used extensively by dyers in preparing stuffs to take the required colours, and forms the basis of the ordinary *Cream of Tartar* and *Tartaric Acid* of commerce. It should be thick, hard, bright, and not too earthy; the white is preferred to the red on this account.

Armenian Bole. — A pale red earthy mineral, or silicate of aluminium, found chiefly in Armenia, but a similar substance is also found in some other parts of Europe. There is, however, no such thing as true Armenian bole in this country, and has not been for the last 150 years. What passes here under that name is a fabrication.

It contains a quantity of red oxide of iron, and is now extensively prepared by grinding together a mixture of whiting, red oxide of iron, and red ochre in nearly equal proportions. An inferior article, made of a mixture of Venetian red and chalk, is often sold in imitation of this ferruginous substance.

Several savage tribes in South America eat *bole* to allay the pangs of hunger, and the Javanese eat small cakes of it, called "tanaampo," to make them grow thin.

It is used largely in tooth powders, also in colouring articles of food, such as anchovy essences and pastes, tomato sauces and conserves.

Arnatto. —See *Annatto.*

Aromatic Cachous.—F. *Cachous aromatises.*

Mouth lozenges for chewing after smoking, to sweeten the breath; originally composed chiefly of catechu and sugar, flavoured and perfumed with strong aromatics, but nowadays the catechu is frequently omitted, and they are prepared in two ways:—

1. 3 oz. extract of liquorice, 40 drops of clove oil, and 10 drops oil of cassia, mixed and made into pills of 1 or 2 grains each, and then neatly silvered.

2. 2 oz. extract of liquorice, 1 oz. sugar, 1 oz. vanilla, 30 drops oil of peppermint, mixed with mucilage and divided.

Aromatic Vinegar. — F. *Vinaigre de quatre voleurs;* Lat. *Aceticum aromaticum.*

A pleasant and volatile excitant generally put on sponge and fixed in vinaigrettes or smelling bottles. It may be prepared from either acetic acid or alcohol, perfumed with certain strong scents or essential oils, such as camphor, oils of cinnamon, cloves, lavender, rosemary, bergamot, neroli; sometimes the dried heads of wormwood, sage, mint, rue, garlic, are also employed, a little spirit being necessary to extract the perfume and make it keep better. It is also known as *Marseilles Vinegar, Vinegar of four thieves,* and *Camphorated Acetic Acid.* It owes one of these names to the story that four thieves preserved themselves by its use from contagion while plundering dead bodies during the plague of Marseilles. A drop

or two of this odoriferous liquid overpowers, but does not really destroy, bad smells. It is very corrosive, so should not come in contact with the skin or clothes, and, being extremely volatile, should be kept closely corked. This vinegar is very good for fainting fits and headaches. It is also sold liquid in small phials.

Arracachas. — The tuberous roots of an umbelliferous plant, botanically identified as *Arracacia esculenta*, which is native to the Northern Andes. It was introduced into this country about 1846, as a substitute for the potato, but the English summer seemed too short for it, and it did not succeed, although it is largely cultivated and eaten in Venezuela, New Granada, etc., and is naturalised in Jamaica, also in the East Indies.

Arrack or **Rack.** — Da. *Arrack;* F. *Arac;* G., Du., and Sw. *Arrak;* It. *Arack;* Rus. and Sp. *Arak.*

A generic name of Oriental origin for spirituous liquors of all kinds, generally colourless, procured either by distillation of palm wine, sap of date shoots, or a fermented infusion of rice, and sometimes made from ordinary fermented grape juice. When well made it is clear, transparent, with a slight straw colour, but in England is only used to flavour "punch."

Goa and *Colombo arracks* are made from the sap, "toddy," or fermented juice of the cocoanut palm (*cocos nucifera*), and procured by incisions, especially by the Cingalese, who have long regarded it as their native drink. There is much illicit distillation, but the Ceylon Government derives considerable revenue from the use of this intoxicant.

Batavia, Java, and Jamaica are made from molasses and rice, with a little toddy. The famous Batavian product is prepared by Chinese from rice, slightly flavoured with cinnamon and anise, and closely resembles the best rum. North Indian is made from molasses only.

Algerian Araki.—The Arabs of Algeria manufacture a kind of spirit which they call *Araki*, from dried figs.

Tungusian arrack is made by the Tartars of Tungusia from sour mare's milk, fermented and then distilled twice or thrice between two earthen vessels closely stopped, the liquor escaping through a small wooden pipe.

Batavian arrack is considered best, then Madras, and that of China, if old, fully equals any other. A factitious kind, sometimes called *Vauxhall Nectar*, is made in this country by dissolving 23 grains of flowers of benzoin (benzoic acid) in one quart of good pale Jamaica rum.

In the East the consumption of arrack is very large, and it is one of the principal products of Ceylon.

Arripa Spirit.—See *Cashew Nuts.*

Arrowroot. — Da. *Salep;* Du. *Pijlkruid;* G. *Pfeilwurz;* Sp. *Maranta.*

A dry, powdery, and nutritive starch, used as a food; made from the pith of the roots of any of the plants of the type *Maranta.* The genuine is *Maranta arundinacea*, a native of South America, but now grown largely in the West Indies, Bermuda, and Port Natal, also in East Indies, under the name of *Maranta indica*, and from *Cwicuma angustifolia.* The arrowroot now grown in Jamacia is said to be almost, if not quite, equal to that of Bermuda. It is cultivated in much the same way as potatoes. The ground being ploughed, harrowed, and laid out in drills about 6 inches deep and 3 feet apart. In these drills the roots are set about 8 inches apart, ploughed over, and harrowed. Bermuda arrowroot owes its superiority mainly to the extreme care and cleanliness used in the different processes of manufacture. (See *Bermuda Arrowroot.*) Other qualities come in large quantities from East Indies and Natal in Africa, each importation taking the name of the place whence it comes. It is said to owe its name of "arrow-root" to the Indians using it to absorb the poison and cure wounds inflicted by poisoned arrows. The plant is a perennial herb, easily propagated by parting the roots. It grows two or three feet high, with branching stems, broad

pointed leaves, and small white flowers. It contains a large amount of farina, and, when pure, forms an agreeable and nutritious food for children and infants.

These fleshy roots when a year old are about a foot long, and as thick as one's finger. They are dug up, washed, peeled, grated or crushed between rollers, and strained through a sieve and the fibrous parts thrown out. The pulp is then washed repeatedly, the milky top liquor left to settle, and the water afterwards poured off. The white starchy sediment is placed in cloths to dry, then boxed or filled into barrels lined with paper fastened on with arrowroot paste, and exported. Adulteration by potato or tapioca, flour, sago, *Tous les mois*, and other fecula is easily detected by the microscope. *Potato Starch*, or *English Arrowroot*, may be distinguished by the greater size of the particles, their coarser and more distinct rings, and their more glistening appearance. *Sago flour* may also be detected by its truncated extremity, and by its irregular and tuberculated surface. Arrowroot is also adulterated with rice starch, and with the common starch of wheat flour.

Natal Arrowroot.—For very many years arrowroot has been cultivated on a small scale in the vicinity of Durban. The Buttery family commenced the culture of arrowroot about 1860, and, as may be supposed, the process adopted in the early days was of the most primitive description. While to-day the root is crushed in a mill driven by a four-horse-power hot-air engine capable of turning out a ton of arrowroot flour a day, the whole business at first was done by passing the roots between a pair of rollers, turned by the ever-necessary kaffir. Later, horse-power was substituted for natives, and to-day the whole mill is driven by an engine which pumps up the water supply from the Umgeni, while it works the crushing mill. Mr. William Buttery cultivates about twenty-five acres of arrowroot annually, and considers three-quarters of a ton of prepared arrowroot a fair average return to expect from each acre. For this prepared arrowroot he receives 3d. a pound wholesale, which represents not more than a penny profit on each pound sold. And as this penny, owing to the introduction of maizena, cornflour, Mellin's food, and a host of other similar articles into the market, is a diminishing quantity, readers will well understand why the cultivation of arrowroot in Natal is confined to about two farms, and is on so small a scale. Although Mr. Buttery's mill is capable of turning out a ton a day of the prepared article, as a matter of fact he finds it useless to produce more than about twenty tons of arrowroot per annum, and this may be easily understood when it is known that the total annual consumption of arrowroot in Natal is only three tons, and that Johannesburg with its enormous population only takes a little more than half a ton annually; the rest has to be exported to England, and, with the keen competition it meets in this country, it only realises a moderate price. Mr. Buttery raises arrowroot much on the same lines as a crop of potatoes. The bulb is planted in rows about eighteen inches apart, and fertilised with kraal manure. From the land the roots when ripe are carted to the mill, and after being first thoroughly washed are submitted to the crushing process. A constant stream of water plays upon the rollers as the roots pass between them, and it is this water which, passing through a great number of sieves, each one finer than the last, contains the arrowroot proper. From the crushing mill and sieving trays it runs in to a number of large vats, and is there allowed to remain undisturbed until the arrowroot has precipitated itself, when the water is run off through the sides of the vats. From the bottoms of the vats the arrowroot is then collected with spades and put into fresh vats, where it is thoroughly mixed and washed with filtered water, and allowed again to settle, after which the water is once more run off. The arrowroot is at the bottom of this vat in a block twelve inches thick. This block is found to have a thin coating of sand and gritty material on its lower side, pure, clean arrowroot in the centre, and a slightly discoloured sur-

face on top. The upper and lower surfaces are scraped off, and the centre, having been dried and bleached in the sun for about four days, is crushed by a slight blow from the hand, when it assumes the shape and appearance common to the ordinary nursery article, which most of us have consumed.

When good, arrowroot is a light opaque white powder, insipid and inodorous, and will keep many years in a dry place. When it is rubbed between the fingers it produces a slight, crackling noise, something like new snow being pressed into a snowball, and when mixed with boiling water it swells up into a consistent jelly. Arrowroot is less apt to become sour during digestion than any other farinaceous food, hence its use for the sick and delicate. When pure, arrowroot is perfectly soluble in cold water, but if adulterated a starchy sediment results. There should be no froth when boiled.

East Indian Arrowroot or *Curcuma Starch* is obtained from *Curcuma angustifolia*, or narrow-leaved turmeric. *British* or *English Arrowroot* is the starch obtained from the potato, as already stated.

Otaheite Arrowroot or "*Pia*" is obtained from the tubers of *Tacca pinnatifida*, and is also known as *Otaheite Salep*, *Tacca Starch*, and *South Sea*, *Madagascar*, or *Tahiti Arrowroot*.

This is a perennial herbaceous plant, with a tuberous root. As a source of arrowroot the plant is of great value. The tubers when fresh resemble new potatoes, and contain a great deal of starch. Tacca arrowroot is preferable to any other in cases of dysentery and diarrhœa.

Portland Arrowroot is from the underground tubers of *Arum maculatum*, or wake-robin.

Brazilian Arrowroot is merely Cassava starch or tapioca-meal from *Manihot utilissima*, known also by the native names of "*Moussache*" (French) and "*Cipipa*."

Florida Arrowroot is obtained from the root of a wild plant resembling the soapweed.

In commerce the word "arrowroot" is now often loosely used as a generic term to indicate any white, tasteless, and edible starch, or fecula; but the Adulteration Act really limits the name "*arrowroot*" to the pure pith of the marantas.

Arrowroot is imported in tin cases, barrels, or boxes, carefully closed up, but is often repacked in smaller boxes and packets. Bermuda, the dearest, is mostly imported in original casks of 100lbs.; St. Vincent, in 200lb. casks; Natal, in cases of 125lbs., and in 7lb. and 14lb. tins. This Natal root (although a variety of *Maranta arundinacea*), first imported in 1853, is only very inferior, usual price 2d. to 3d. per lb.; while Bermuda is worth 1/- to 1/6 per lb.

Gardner's Patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Arrowroot Importers—Morris & Jones, Sir Thomas Street, Liverpool; Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Arsenical Soaps.—Some of these are saponaceous preparations for use in stuffing birds and small animals, to preserve skins from natural decay and from the attacks of insects.

They consist of soap mixed with a little arsenious acid or commercial arsenic. There is, however, no standard, and some of these soaps sold for toilet purposes contain no arsenic whatever. As outward applications for the skin, arsenious powders, soaps, etc., have long been popular among fashionable ladies for producing temporarily an increased brilliancy of the complexion, but if arsenic is present they can now only be sold by registered chemists (see "Poisons Act"), and if the soaps contain no arsenic the purchaser is prejudiced by not getting what is asked for.

Artichokes. — Du. *Artisjok*; F. *Artichauts*; Ger. *Artischoken*; It. *Carciofano*.

A corruption of the Armenian word *ardischauki*. The plant is not a dis-

tinct species but a derivative of *Cynara Cardunculus* or *Cardoon*, and is classed as *Cynara Scolymus*, closely resembling a large thistle-head, hence the term "Globe" artichoke. The Cardoon grows wild, but the artichoke is not found anywhere in a wild state. Each head consists of (1) the *leaves*, (2) the tender inside called *choke*, and (3) the *bottom* of each scale or solid white part, called by the French "*Fonds d'Artichauts*." These thick fleshy bases or "Fonds," with the pappus of the innermost florets, are the most toothsome portions, and are dried and also preserved in tins. The tender heads, gathered before the expansion of the flowers, are boiled and eaten with oil, butter, or gravy, and seasoned with salt and pepper. They are also sometimes dried for use in winter.

The plant is of Greek origin, a native of Asia, and both the Greeks and the Romans called it *Cynara*. It may also be called a maritime plant, for it loves proximity to the ocean, and was introduced into England about 1570. Its roots are perennial, its stems annual, and it is usually propagated by suckers. There are two popular varieties: (1) the *Conical* or *French*, "*Artichaut Vert de Laon*," which is of a milky green colour, with the scales spreading; (2) the English "*Crown*" or "*Globe*" *Artichoke*, which has its scales tinged with purple curved inwards, and closely folding over each other. *Drumhead* is the best. Those grown in Naples and Campania are considered the largest, tenderest, and best flavoured, also the most fruitful; then come the French. Spanish artichokes grow dark purple, tall, and upright, with the buds hidden from view. Sometimes they are nearly black, but the further north they are grown, in rainy, foggy climates, the violet colour entirely disappears, and is replaced by green or grey-green. It grows on an erect flower stem, two or three feet high, is considered a great dainty, and frequently eaten raw. Indeed, all parts of the early plant are pleasant eating—roots, leaf-stalks, stems, and flower heads. The better varieties are the least prickly. The roots are said to be somewhat purgative. In cultivation it requires great care, and it does not appear to grow well in this country. Artichokes are better after being gathered two or three days, and the heads are usually cut with a stalk and a neighbouring leaf, before the purple flowers expand. They are in season in July, August, and September. In France two crops are raised, one from spring buds in May and the other in September, but the spring growth only is eaten raw. To eat an artichoke gracefully is a rather rare accomplishment. Knives and forks are useless, and not only are the fingers soiled, but a heap of debris left on the plate is often disagreeably suggestive of a midden heap. (See also *Cardoons* and *Jerusalem Artichokes*, etc.)

Artificial Manures. — See *Fertilisers*.

Arva or **Kava.** — See *Ava*.

Asbestos (also known as *Amiantus*, *Amianuthus*, and *Mountain* or *Earth Flax*).—F. *Amiante*; G. *Asbest*; It. and Sp. *Amianto*.

This is a variety of hornblende. It is a soft, fibrous, yet crystalline and incombustible, metallic substance, often used for spreading over the burners of gas stoves in order to form incandescent radiation. This wonderfully silky earth-flax is mined in Italy, Canada, and in several of the United States. It is also found in various parts of Arcadia and Europe and in Scotland and Cornwall, but Italy and the province of Quebec are the only sources supplying commerce. The ancient Greeks used to weave it into an indestructible cloth.

The name "Asbestos" is itself derived from a Greek word signifying incombustible, or inconsumable; and "Amianthus" is also from a Greek word meaning unstained, or undefiled.

It has been called a mineralogical vegetable, and is certainly one of the most marvellous productions of inorganic nature.

There are several varieties. They contain a considerable percentage of silica and magnesia in their composition,

and are of various colours, whitish, greyish, greenish, brownish, and black. The flexible and elastic fibres of asbestos being quite incombustible, renders it very useful for lamp wick, paper, firemen's clothing, ropes, and packing for steam joints. It is also recommended for roofing buildings. In 1861 the roofs of Kingsford's Oswego starch factory were covered with asbestos, which is still in good condition. The wealthy Romans ages ago used it as a shroud in which to fold their dead previous to placing them on the funeral pyre, in order that the clothes might retain the ashes of the corpse. Pliny relates that he has seen soiled napkins made of this substance thrown into the fire, and better cleaned by it than by washing.

When required for the making of cloth, lamp-wick, etc., the crude substance is first soaked for a long time in warm water, and afterwards opened and divided, in order to separate the earthy parts which are whitish, like chalk, and serve to bind the fibrous parts together. This operation is repeated six or seven times, with fresh water, still opening and squeezing the mineral, till all the loose particles are washed out. Then the flax-like parts are laid out on a sieve to dry. When thus cleansed it is carded gently, and then reeled, being kept, at this stage, moistened with oil.

Ashes.—An old trade term for the common wood ashes or other alkaline matter obtained by burning wood, seaweed, and in lime or otherwise; used formerly by housewives to soften water. (See *Potash*, *Pearlash*, etc.)

Asparagus or **Sperage.** — Da. *Asparges;* Du. *Aspersie;* F. *Asperges;* Ger. *Spargeln;* It. *Sparago;* Port. *Aspargo;* Rus. *Sparsa;* Sp. *Esparrago.* This well-known and succulent vegetable, *Asparagus officinalis*, often vulgarly miscalled "grass" or "sparrow-grass," is a perennial root and has annual stalks, which are cut off when they are six or more inches above the ground for culinary purposes. There are two kinds of asparagus—green and the bluish-red or violet; the former is much the better flavoured, but the latter, being more showy and larger, is preferred by gardeners, who vie with each other in producing monster heads. Some kinds are armed with strong prickles. Asparagus is raised from seed, and grows best in a rich, fresh, sandy soil. Large quantities are grown in the beautiful vale of Evesham in Worcestershire, also at Deptford and Mortlake in Surrey, where hundreds of acres are devoted to its cultivation. Most of the sticks cultivated in France and Holland are blanched nearly their whole length, and for export are packed in cases of two dozen square tins, 2lbs. to 5lbs. each, and in long tins containing from twelve to sixty sticks in each. Argenteuil, near Paris, is famous for this vegetable, and immense quantities are grown in that locality. The choicest quality, *Pointes d'Asperges*, are packed in 1lb. tins. Broken sticks are generally packed in 1lb. tins for soups, etc.

Like tinned peas, tinned asparagus is very liable to contamination with the lead contained in common kinds of tin. A single dose of this mineral poison taken into the system may not be fatal, but taken frequently serious effects have resulted.

Asparagus is not of much value as a food, but very delicate and delicious in character, also easily digested, but it imparts a very disagreeable odour in the urine of some persons. It seems strange that English farmers do not grow and tin it, as well as market it in bunches. It is very popular in France, and the grocers there sell large quantities, done up in bunches of a kilogramme (2¼lbs.) each. No other vegetable retains its flavour so well after preserving.

It is often substituted by or mixed with the young stalks of artichoke, alisander, cardoon, rampion, sea-kale, and burdock (*Articum Lappa*), that well-known plant from which children often gather the burrs to throw at each other for the fun of seeing them stick on their clothes or hair.

Very excellent asparagus now comes from Bouldon Island, California, where

the soil and climate seem admirably suited to its cultivation. Years ago it was discovered that the overflow and tule lands along the coast and river islands in the Central Western part of the State were specially suitable for the culture on a large scale. Both climate and rich soil united to produce crops in quality and quantity unsurpassed in any other part of the world. It is easy to can, "handles" well, and is not easily bruised or defaced; requires the simplest of preparation and cooking, and keeps its fresh appearance. In 1888 only about 120,000 tins of 2½lbs. were sold during the season, but in 1898 about two million tins were advantageously disposed of, and large new asparagus farms are still being started.

The beds are not cut after June 10th, and are planted so that new areas come into bearing every year. Great care seems to be taken in the selection, for the quality is very high, and each tin contains spears of grass alike in size, tenderness, and flavour, besides being uniform in weight. The best is the "peeled white." A shilling tin is sufficient for three or four persons, and can scarcely be distinguished at table from fresh asparagus.

Asphalt. — A mineral pitch from Trinidad, France, and Switzerland. (See *Pitch*, *Manjak*, etc.)

A vast and inexhaustible deposit remains practically untouched in Venezuela, but one lake, that of Guanoco, in the State of Bermudez, is now being operated by an American company.

Aspic and Aspic Jelly. — Ger. *Gewurz-Sulze.*

Aspic is a savoury dish, composed of game, fish, hard-boiled eggs, etc. Sometimes it is made from calves' feet, a knuckle of veal, ham, onions, carrots, and savoury herbs, flavoured with sherry or tarragon vinegar. *Aspic Jelly* is a savoury jelly of an amber colour extracted from the succulence of meat or from gelatine, and is used as an exterior moulding for decorating or ornamenting cold game, hams, tongues, raised pies, galantines, poultry, fish, etc. The jelly being of a light transparent nature allows the article which it covers to be seen through it.

Assam Tea. — See *Indian Tea.*

Assarabacca or Cephalic Snuff. —A preparation of assarabacca leaves mixed with scented snuff, and considered very good for clearing the head.

Asses' Milk. — Very sweet and easily digested. Often ordered for delicate children and invalids, because it contains only a very little of that indigestible milk constituent known as *casein*, and also less than one per cent. of cream or fat, whereas cows' milk contains twelve to twenty-four per cent. of fat, and human milk about three per cent.

Assmannshauser Wine. — Produced in Germany on the banks of the Rhine about three miles from Rudesheim. The quantity is small, but the quality is the best of the red varieties of Hock, and it was famed as far back as 1108. Good vintages fetch £5 to £10 per aum (about 41 gals.).

Asti Wine — One of the best qualities of sparkling wine produced in Italy, and called after the northern province of Asti.

Astral Oil. — See *Kerosene.*

Atkinson's Infant Preservative. —Appears to consist of carbonate of magnesia 6 drachms, white sugar 2¼ oz., oil of aniseed 20 drops, sal volatile 2½ fluid drachms, laudanum 1 drachm, syrup of saffron 1 oz.; with caraway water added to make up a pint.

The use of such drugs has been severely condemned by many medical authorities, coroners, etc.

Atora Beef Suet. — See *Hugon's Refined Beef Suet.*

Attar of Roses. — See *Otto of Roses.*

Aubergine. — See *Egg-plant.*

Australasian Butter.—The growth of the butter exports from the Australian colonies has been quite remarkable. In 1889 the exports to Great Britain

amounted to about £6,000; in 1890, to £35,000; in 1891, to £106,000; in 1892, to £265,000; and in 1893, to £547,000. During 1894 the imports reached over 11,000 tons, chiefly from Victoria, *viâ* Melbourne.

The butters generally arrive here in square boxes of 56lbs. net. They should be consumed in a few days after leaving cold storage or the flavour suffers. The disagreeable flavour noticeable in some of them is attributable to the fact that colonial salt has too often a bad mineral taste, and that this imparts to the butter the unpleasant flavour. Colonial dairymen are, however, beginning to use English salt—at all events for butter to be sent here. There are several factories in operation which buy their milk at sixpence or sevenpence a gallon, and the Government is doing its best to promote the business. The colony of Queensland has now become a regular exporter of butter to Great Britain. This butter has competed on fairly favourable terms with the produce from Victoria, New Zealand, and other colonies. It is well liked but sometimes lacks the uniformity of quality so important in the British market. However, with lower railway rates in the colonies and lower freights to this country, there are possibilities for great extension of the trade in these butters. The selling of the finest brands of Australian and New Zealand butters that come into England is now mainly in the hands of Geo. Wall & Co., Ltd., Liverpool and Manchester.

Australian Moss. — This has been introduced for the same uses as Irish, Ceylon, and other mosses, but has not been very generally adopted. It is prepared by soaking half an ounce of the moss in water for an hour or two; the water is then poured away and the moss boiled in a quart of fresh water till dissolved. It is finally strained through a hair sieve, sweetened, and flavoured to taste.

Australian Tea. — Also called *Tasmanian* or *New Zealand Tea.* These are mere substitutes for tea, and consist of infusions made from various species of tea-trees (ti-trees) of the myrtle order growing in the above countries, sometimes as shrubs, 1 to 12 feet high, but often as trees 40 to 80 feet high.

Custom-house returns show that the inhabitants of Australia and New Zealand consume per head more of genuine imported tea than any other people outside China.

Australian Tinned Mutton.—F. *Mouton;* G. *Hammelfleisch.*

Most of the tinned mutton comes from Australia, where sheep are very plentiful and cheap; it is said there are thirty sheep to each inhabitant, while in England there is scarcely one. The prejudice existing in this country, especially among the working classes, against Australian mutton, although not so prevalent now as it was a few years back, is, however, very absurd. It should be remembered that the first sheep in Australia were sent there from the finest English breeds in 1809—to feed convicts, it is true, but that was not the fault of the sheep. Others argue that the grass is of poor quality because the soil has not been properly tilled, and that the result is the mutton is not so satisfying unless a man eats about one-third as much again of it as of English mutton; but the sheep feed in Australia on natural grasses and in the open air, and, as a consequence, their flesh has a flavour and strength superior to that of the artificially fed animals of this country—and far superior to the scraps and remnants of inferior or diseased animal food sold by unscrupulous farmers and butchers in all our large towns. In Australia there is little temptation to tin bad stuff. Every year thousands and sometimes millions of sheep are boiled down for their tallow only, which realises about 4/- a head, and even the best raw meat costs only about 1d. per lb., but the tinning costs 2d. to 6d. per tin, according to size. A 2lb. tin of this mutton may be said to be equal to 3lbs. of raw butchers' meat. In comparing the economy of tinned mutton with butchers' fresh mutton, the relation of bone to the meat is important. The average weight of the bone in a leg of mutton is 1lb., a shoulder of 7lbs. also

contains about 1lb. bone, and as the bone is not eatable, it adds 1d. or 1½d. per lb. to the cost of the meat.

How prepared.—The tins are filled with about 2¼lbs., 4½lbs., or 6lbs. 10 ozs. of raw mutton without bone. After the mutton is placed in the tin the top is soldered on, and a small hole left in the centre. The tins are next placed on a gridiron in a bath of salt and water, called the chloride of calcium bath; and the bath is heated to a temperature of 220°, afterwards to 230°, and finally to 260°, the time occupied being about three hours. This last is a temperature of 48° hotter than boiling water, and is said to be necessary to remove all the air and life germs; every little cell containing air and water is broken up, and the steam and air escape at the small hole, which is suddenly closed with the soldering iron, all the elements of decomposition being thus removed. The tins are put aside to cool, when the external pressure of the atmosphere often forces the top into a concave or battered shape, but the tins are never reopened until the meat is required for the table. A portion of the flavour escapes with the steam, and most of the *osmazome*, upon which the flavour of the meat depends, has been separated by the boiling, but, while the flavour of the mutton is somewhat injured, the flavour of the jelly is increased.

Short Weights.—The *Melbourne Argus* gives a hint to English consumers: "Complaints have reached us from home that tins of Australian meat are sometimes not exactly up to weight, and some are as much over weight as others are under. It must be at once admitted that Victoria meat preservers find it difficult, if not impossible, to achieve perfect uniformity in the weight of their tins. The same weight of uncooked meat, put into cans of exactly the same dimensions, will sometimes turn out, when ready for the market, some few ounces above or below 6lbs., or 4lbs., or 2lbs., as the case may be. The manufacturing practice is to put 6lbs. 10 ozs. of meat into the 6lb. tins; 4lbs. 7 ozs into the 4lb. tins, and 2lbs. 4½ ozs. into the 2lb. tins, in order to provide against the loss of weight which occurs during the cooking process, and this generally is ample, the tins when finished proving rather over than under the intended weight. Some manufacturers let the over-weight tins go for the weight they were intended to be, and sell those of less weight, be the deficiency ever so slight, as if ¼lb. short.

"Others charge for excesses as well as allow for deficiencies. On one point the European consumer may rest assured—the Australian meat preserver never intentionally sends out his tins deficient in weight. He has nothing to gain and much to lose by such a practice. An ounce or two of mutton is nothing to him, whereas to permit his manufacture to fall into discredit would be utter ruin."

A considerable quantity of tinned mutton is also now put up in the United States.

According to a statement in the *Adelaide Observer* (1895), the total number of sheep in the world is estimated to amount to 555 millions, and nearly one-third are of the fine woolled "Merino" breed.

Of these 555 millions,	Millions.

For tinned mutton, apply to Morris & Jones, 13, 15, and 17, Sir Thomas Street, Liverpool (also proprietors of the "Southdown" brand).

Australian Wines. — The first grape vine in Australia was planted at

Castle Hill, near Sydney, in 1791, by Colonel de la Campe, a French emigre. The first grape vine near Parramatta, a few miles from Sydney, and famous for its orangeries, was planted in 1801. After the fall of Napoleon in 1815, Mr. John Macarthur, a spirited colonist, while in Europe, obtained a number of cuttings of the finer varieties of vine, but the London nurseryman to whom they were entrusted for despatch to Sydney, substituted others of an inferior kind. The trick was not discovered until several years afterward, the soil and climate of the colony being in the meantime blamed for the failure of the experiment. In 1825 cuttings of the Muscat and Madeira varieties were sent to Sydney and thrived splendidly. Other cuttings followed, but the British Government refused to grant passages to Continental vine dressers, and it was not until 1844 that such men found their way into the colony. Thenceforward the progress of vine cultivation was rapid, and with its increasing spread the production of wine became a recognised industry. In 1861 there were in New South Wales, Queensland, South Australia, Victoria, and Western Australia, 7,009 acres under vine cultivation; in 1896 the area had become increased to 58,642 acres, the product being 5,606,035 gallons of wine, 7,901 gallons of brandy, 63,665,280lbs. of table grapes, and 2,145,360lbs. of raisins. The grapes grown in New South Wales are equal in size and flavour to the finest grown in Continental Europe, but both their cultivation and the production of wine from them remain imperfectly developed as a whole. In 1897 the area under wine cultivation in the colony was 8,061 acres, producing 794,256 gallons of wine, 7,134 gallons of brandy, and 6,462,400lbs. of table grapes. The raisin manufacture is still one of the industries of the future in New South Wales. In 1893, with 462 acres less under cultivation than in 1897, the quantity of wine produced was 931,542 gallons. Most of the vineyards are of limited extent, but several are of large size. They are scattered over the whole of the colony, save on the more elevated tablelands and in the sub-tropical regions. There are over 2,000 vignerons in the colony, the most successful being Italians, Germans, and Frenchmen, or individuals having some practical knowledge of vine cultivation as practised in Europe. The colony offers an unlimited field for enterprise in this direction, there being many thousands of acres eminently adapted for vine cultivation remaining unutilised. It has been stated by a leading authority that New South Wales is more favourably situated for raisin production than is any of the other colonies, and that when the industry has become introduced and firmly established a large intercolonial and export trade may reasonably be anticipated. Of the 16,695,560 gallons of wine imported into Great Britain in 1896, only 6,394 gallons were from New South Wales, most of that produced in the colony being locally consumed. Such is the abundance of grapes, mostly the black varieties, in the colony, that during the season they are retailed at 1d. per lb. in Sydney, the finest muscatels bringing from 3d. to 6d. per lb. In the vicinity of the vineyards they are cheaper still.

The increase of vines in the different colonies in 1892 was:—Victoria, 26,443; South Australia, 15,418; New South Wales, 8,264; Queensland, 1,908; West Australia, 1,218—total, 53,251. Victoria now produces nearly half the wine made in Australia. In South Australia a large number of Germans are employed in the industry of wine making, but the best Australian products are still scarcely equal to the second class of French wines. The best which Australia produces is one called *Cwarra*, which much resembles a second-rate Rhenish wine.

Other Australian kinds are:—

Tintara (described elsewhere).

Muscat of Alexandria, a white wine.

Hocks, from the (1) Chasselas Grapes, (2) Auldana Reissling, and (3) Porphyry.

Sparkling Verdeilho Champagne, *Burgundies* from Hermitage, Golden Fleece, and White Burgundy.

Gouais.

Carbinet, a soft wine, like Burgundy.

Mataro.

ALKANET (see page 34).

ANISE (see page 47).

ARROWROOT PLANT (see page 57).

ARTICHOKE (see page 59).

Sauvignon.

Kaludah, an elegant dinner wine.

Singleton Red, or White *Hermitage*, noted for its refinement.

Tokay Imperatrice.

Verdeilho, of a delicate aroma and full body; colour, partridge-eye; with 20 to 30 per cent. alcohol.

Frontignac, a thin, white wine, with a kind of elderberry body.

Malbec, made from the claret grape, and contains about 23 per cent. proof spirit.

White Adelaide, an exquisitely pure wine from Riessling grapes.

Red Adelaide, a kind of Burgundy, very hot, but of mild flavour.

Tavoora, a kind of port with about 27 per cent. alcohol.

Chasselas, a poor and acid variety.

Highercombe, like Sauterne and strongly scented.

Wattlesville is acidulous and of no particular quality, the cheaper kinds being mousy and vinegary.

In 1892 South Australia produced about a million gallons, and exported about 325,000 gallons.

The production and export of wine for 1897-8 are interesting at the present time. The balance reserved for home equals 1¼ gallons per head of total population. The British imports of wine equal 14,000,000 gallons altogether.

	Production. Gals.	*Export. Gals.*

Victoria	2,750,000	346,030
Western Australia	120,000	156
	5,225,553	917,268

Thousands of acres of vines are being planted in Australia, looking to the London Market as an outlet for the wine in future years.

Austrian Wines.—Some of these are very good, but not very widely known.

The principal kinds produced are:—Steinberg, Voslauer, Auspruch, Tokay, Menos, Buda or Ofen, Carlowitz, Œdenburger, Muscat, Szamarodi, Erlauer, and Giberwein.

Ava, Arva, Kava, or **Yava.**—A favourite and intoxicating beverage with the inhabitants of the Samoan, Friendly, Fiji, and other islands in the Polynesian group.

It is derived from the roots of the plant *Macro-piper methysticum*, which is closely allied to the pepper family.

In some places the natives merely chew the root, which has aromatic and pungent qualities, add water to the result, and this, by fermentation and straining, produces intoxicating beverage.

In South-Eastern Asia the leaves of the plant are chewed with *bêtel*.

In the Colonial and Indian Exhibition, 1886, a spirit was retailed at the refreshment bars which was distilled from the roots of the Kava plant. It was sold under the name of *Kava Schnapps*, or *Yangona*.

Avena Flakes or **Flaked Oats.**—*Avena* is the Latin name of the oat genus of plants, hence Avena Flakes is simply a fancy term for crushed, rolled, or flattened oats.

Avignon Berries.—See *Yellow Berries*.

Avocado or **Alligator Pears.**—(sometimes called *Aguacute* or *Midshipman's Butter*).—The fruit of *Laurus Persea gratissima*, grown in tropical America, in Florida, and in some of the Atlantic Islands. In Madeira, where large quantities are grown, the tree attains a height of 20 to 30 feet, and forms a tree of tall, slender growth, with smooth green laurel-like leaves. The fruit, which is shaped like a large pear, grows in clusters, the number of fruit in a cluster varying from three to five; when ripe, they assume a dark purplish-green colour, and each fruit contains a large globular seed, around which, and connected to the very thin skin, is the pulp or edible portion, which, in some of the French colonies, is known as "*Vegetable Butter*."

The local name for the fruit in Madeira is "*Peara da Manteiga*" (butter-pear). The pulp has the consistency of butter, with a delicate nutty flavour. It is commonly eaten as a salad, seasoned with pepper, salt and sometimes a little vinegar, or the juice of a fresh lime. Others prefer to use it as a dessert fruit, with a little sugar. The fruits are in season from middle of September to end of February, and some are exported to London. They are gathered before quite ripe, and expected to mature afterwards. In Grenada these pears are always eaten in a raw state, with bread and butter or other things, according to taste. It is said that cats are very partial to them. In the West Indies, where it is much esteemed, the taste is rather oily and pastey, but it is considered an excellent fruit, and a fancy for it is soon acquired.

Awamori.—A strong spirit made in Japan from rice.

Axle Grease.—Made in several ways:—(1) Water, 1 gallon; soda, ⅓ pound; palm oil, 10 pounds. Mix by heat, and stir till nearly cold. (2) Water, rape oil, of each 1 gallon; soda, ⅓ pound; palm oil, ¾ pound. (3) Water, 1 gallon; tallow, 3 pounds; palm oil, 6 pounds; soda, ½ pound. Heat to 210° F., and stir until cool. (4) Tallow, 8 pounds; palm oil, 10 pounds; plumbago, 1 pound. Makes a good lubricator for waggon axles.

Ayapana Tea. — Consists of the leaves of *Eupatorium triplinerve*, or better known, perhaps, by its older name, *E. ayapana*. The plant is a native of tropical America, where it has long been used, particularly in Brazil, as a sort of panacea, or domestic remedy for everything.

This tea is very popular in the Mauritius, Java, Ceylon, India, and other tropical and sub-tropical countries wherever it has been introduced, and is considered very good as a stomachic tonic in indigestion.

Ayer's Pills.—Sold in long wooden boxes, each containing twenty-five pills, composed of pepper, colocynth, gamboge, gutti, and aloes, and covered with sugar and starch.

Ayer's Hair Vigor.—A solution of 0·6 per cent. of lead nitrate.

B

Baba. — G. *Polnischer Kuchen*. A sweet cake made with yeast and raisins.

Backstein Cheese.—A Continental make, containing water 37·4, fatty matter 30·6, casein 28·5, and salts 3·5.

Bacon. — (See also *Bath Chaps, Brawn, Hams, Lard, Pigs, Pork, Sausages, Rolled Bacon, Sugar Cured Bacon, etc.*)—Da. *Flesk;* Du. *Spek;* F. *Lard;* Ger. *Speck;* It. and Sp. *Lardo;* Pol. *Slonnia;* Port. *Toucinho;* Rus. *Solo;* Sw. *Fläsk;* W. *Baccun, Cig moch.*

Bacon is the sides, belly, and forelegs of the pig, cured and dried.

In England, the counties of Cumberland, Yorkshire, Hampshire, Berkshire, Somersetshire, and Wiltshire have long been noted for excellent bacon; and in Scotland, the counties of Wigtown, Dumfries, and Kirkcudbright. Ireland also cures and exports large quantities of splendid quality, especially of "*rolled*" *bacon* in bales; and importations of good Danish bacon have increased very much these last few years. But the largest quantity, the poorest quality, and the lowest priced comes from the United States. The cost of feeding in the U.S. and Canada (chiefly Indian corn) is very much less than in England, where, although there is no regular system, pigs are mainly fed on barley-meal, boiled potatoes, and separated milk. Bacon from maize-fed pigs containing much more *olein* than English dairy-fed has therefore a lower melting point and is much more wasteful in cooking (see *American Bacon*). Bacon curing in England is mostly done in winter. A moderate temperature is

best. If too hot and muggy, the meat spoils before the pickle has time to act on it; if too cold, the meat sets too stiff to allow the salt to penetrate. The curing may be done by rubbing well the hams and sides of the pig with a mixture of salt and saltpetre—say one part of saltpetre with fifty of bay salt. Some people also use as much soda as saltpetre, and the soda will correct acidity, but impairs the flavour of the meat. Others use a mixture of 4lbs. salt, 1lb. sugar, and 2¼ ozs. saltpetre. The sugar imparts a nice flavour, prevents hardness, and is a good antiseptic. A good rubbing is considered sufficient for the outer or skinny sides, but rubbing the fleshy side makes the surface too hard. It is then laid in a large trough, tub, or other suitable vessel, but so that the liquor may drain away, for, if permitted to soak into the bacon, it imparts a strong rusty or sea-pork flavour, very objectionable to most persons. The parts of the pig are laid in the vessel with the skin side down, and the inner, upper, or fleshy part is carefully covered with the dry-salt mixture, which should be changed every three days, or the salt will give a nasty taste. After lying 8 or 10 days in salt, the bacon is hung up in a dry and airy position to drip, dry, and harden, after which it will keep good any reasonable length of time in a proper situation. It has recently been stated that a sprinkling of hops in the brine when bacon and hams are put in pickle adds greatly to the flavour of both, and enables them to be kept an indefinite period. Smoked hams and bacon are best cured in smouldering oak sawdust, which imparts a very fine flavour, but the meat should remain in pickle about four weeks previously. Oversmoking brings on reastiness, but this is usually prevented by first dusting the meat liberally with peameal and oatmeal. (See "*Smoked Meats.*") Salt cured bacon should not be exposed too long to the air, or it may turn more or less rancid or rusty. It may be easily kept good and sweet by being placed in a box covered six inches deep with clean dry woodashes, and after placing the bacon in, adding another layer of the ashes on the top.

Irish and Danish are treated much in the same mid-cure method. The bacon, instead of the heavy salting and long hard-drying in vogue up to a few years ago, is only kept in the cellar about 10 days, and is just sufficiently cured to have a nice mild flavour without too much salt.

Bacon is also liable to the attacks of a small fly, the larvæ of which are called *jumpers*, or *hoppers*. To prevent the waste it is common to dust the fleshy parts over with a preservative composed of ten parts of flour, six parts of ground pepper, and six parts of powdered borax, well mixed together, and to tie the bacon in bags, or cover it in dry bran. It used to be a common practice to whitewash the flesh sides of bacon as a preventive of reastiness and fly-blowing. The modes of cutting up, curing, and using the several joints vary in different counties and districts. Sometimes the ribs are taken out before curing the sides, but this is a bad plan and allows the underlying meat to be afterwards impregnated with salt and air, and spoiling its taste. The ribs are not of much value when taken out, but of great service if left in, by forming a protection to the inside meat. Of "cuts" we have the *Cumberland* cut with the ribs and foreham left in. This cut sells well, and makes no waste. The Cumberland pig is killed and cured in the cold months of the year, and hung six or nine months in rooms for the purpose until wanted. It has, therefore, to be made very salty. *Wiltshire* cut is cured with both hams and the ribs left in, but the blade bone is taken out of the shoulder.

Auto-cured Bacon.—This is a new process, an automatic vacuum one, the brine by this method being forced into the meat in an incredibly short space of time, causing the bacon, which may have formed a living pig in the morning, to be perfectly cured bacon in the evening. (See "*Wiltshire Bacon.*")

Devonshire Method of Curing.—Draw away all the slime and blood from two hams by rubbing them well with salt for two days before they are put into the

pickle. Drain them, lay them in a pan, and pour over them, boiling hot, the following ingredients:—2lbs. of treacle, 2 ozs. of saltpetre, 1lb. of common salt, and 1 pint of good vinegar; turn and baste them every day for a month, then drain and smoke. Time to salt, one month.

"Sixes" is a term commonly used in baled bacon trade, and means that a bale contains six smaller sides to make up an equal weight of one with four larger or heavier sides. Good bacon has a thin rind, bright and red colour, and agreeable smell; the fat is firm, and of reddish tinge; the lean is tender, and while raw sticks to the bone. When the fat is yellowish it is rusty, or going so. Bacon exposed to strong light, as at shop doors, or in window, etc., loses colour and flavour very quickly. It also lends itself largely to evaporation, and the parings, scrapings, etc., necessary to keep a nice show are apt to result in serious loss unless carefully managed. As to fixing retail prices and weighing out, it is a necessary precaution for the provision hand to cut up a side now and then, weigh and reckon up exactly to see what he realises. It will be an excellent check as to the amount of profit or loss he is making. Bacon should be prepared from young and well-fed animals; it is then a very wholesome and palatable food; contains less water and loses less in cooking. Bacon forms a notable exception to most flesh meats in being more digestible when cured than when fresh. The best way to cook it perhaps is to toast or broil it in rashers in front of the fire; if fried in a pan it is stronger in flavour and less wholesome.

Altogether, Great Britain imports about £10,000,000 worth of bacon and hams yearly. Roughly, a quarter of the money goes to Denmark, nearly half to the U.S., and about one-fourteenth to Canada. (See also *American* and *Danish Bacon, etc.*) The terms "Wiltshire Cut" bacon, "York Cut" hams, "Cumberland Cut" bacon, etc., being well understood by traders, are considered permissible in wholesale quotations as denoting that the hams or sides have been cut or dressed according to the fashion usual in such counties; but for retailers to apply such terms to fractions of the meat is calculated to deceive consumers, and is, therefore, considered an offence under the Merchandise Marks' Act. English bacon-curers in buying and paying for pigs by weight usually claim 4lbs. per pig as waste, shrinkage, or difference which occurs in "cooling" or between killing and salting.

Special Firms.—Hillier's Bacon Curing Co., Ltd. (Wiltshire), First Prize Medal Brand, Newmarket, near Stroud. Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool. R. Rutherford & Co. (Canadian Bacon), 112 Whitechapel, Liverpool. George Wall & Co., Ltd., Provision Merchants, Liverpool and Manchester: Sole Agents for the celebrated "Royal Dane" and the "E.S.M." brands of Danish bacon; also the "Runic," "Wallflower," and "Walnut" brands of American Bacon; telegrams: Walsalls, Liverpool (see advt., p. 10.). Thomas Wilson & Co. (Irish Bacon), 3 Hood Street, Liverpool.

Badian or **Badiane.** — An Indian species of star anise; the fruit of a tree which grows in China, and identical with the European star anise fruit. The Chinese often use the Badian to give their tea an aromatic taste. (See *Anise*, p. 66).

Bael Fruit.—A popular product of Ceylon.

Bagasse. —A name for the crushed or exhausted sugar canes after the juice has been extracted. The same name is given in some countries to the *marc* of grape skins and olive refuse, after they have yielded their juice.

Bags. —F. *Sacs;* Ger. *Sacken.*

A great number of articles in commerce are sold by the bag, which means no more than that the bag, being made of a determined size, is supposed to contain a certain weight, which is generally taken in the gross, and without weighing, for the sake of expedition.

A bag of hops is from 2½ to 3 cwts.; of almonds, 3 cwts.; of aniseed, from 3 to 4 cwts.; of pepper, 1¾ to 3 cwts.;

rice, 1½ cwts.; cleaned, 2 cwts.; nuts, 178lbs. when new, or 154lbs. if old.

The dimensions of most kinds of foreign bags in use are:—

Australians	...	about 28 × 44 inches.
Bombays	...	,, 27 × 44 ,,
Chilians	... ...	,, 28 × 44 ,,
Calcuttas	..	,, 29 × 40 ,,
Beets	... ...	,, 24 × 45 ,,
La Platas	...	,, 22 × 40 ,,
,,	...	,, 24 × 40 ,,
Sugars	... ...	,, 26 × 44 ,,

Americans, made of cotton, are of 7 and 10 stone capacity; also made of jute, of 10 and 20 stone capacity.

Any of the above may be purchased in large quantities (new or second-hand) at Liverpool or any of our large ports.

Baillie's Pills. — See also *Patent Medicines.*

These seem to be composed of aloes extract, colocynth compound extract, Castile soap, and oil of cloves.

Bair Fruits. — The large egg-shaped fruit of the umbrella-topped Bair-tree (*Zizyphus*), very common about Delhi and other parts of India.

Baking Powders. — See also *Easteleine.*

These are substitutes for yeast in raising bread, or to save butter and lard in making cakes, etc. They are all mixtures of acid and alkali, which, on the addition of water, enter into chemical reaction and evolve carbonic acid gas. Hence they are commonly a mixture of tartaric acid, or cream of tartar, and bi-carbonate of soda; and to keep these dry or prevent their coming in contact and acting on each other before wanted for use, and also to cheapen the mixture, either arrowroot, potato flour, maize flour, or rice flour is generally added. Baking powders should be as nearly as possible neutral, and the ideal quantities of soda and acid to aim at are bicarbonate of soda 8½ parts and tartaric acid 7½ parts. Excess of alkali will also darken the pastry. An extra good baking powder might be made of 8lbs. bi-carbonate of soda, 5lbs. cream of tartar, and 2lbs. tartaric acid. The ingredients should be dried thoroughly before mixing, crushed fine, and passed through a sieve, and the baking powder be kept in closed vessels from the air as much as possible, and in a dry place. In drying tartaric acid and cream of tartar care must be taken to do it very slowly, and at a very low temperature, or too great heat will turn them a dark colour. A quarter of a pound of above is mixed by well sifting it with 12lbs. of flour before the milk and water is added, and then made up quickly and baked. The water liberating the carbonic acid gas, and puffing up the dough, the baking should be done before it all escapes. Acid sulphate of potash is sometimes used as a substitute for tartaric acid in cheap qualities of baking powders.

Weight for weight cream of tartar is not really any cheaper for baking powders than tartaric acid; for the latter having a much stronger neutralising power on the bicarbonate, it goes farther. Cream of tartar is used because it is more slowly soluble, and so causes the more gradual evolution of carbonic acid, which gives a greater porosity and lightness to the mass of dough.

BORWICK'S seems to contain a liberal proportion of maize-flour.

GOODALL'S appears to be a compound of two parts of rice-flour with one part of a mixture of tartaric acid and bi-carbonate of soda.

DELFORT'S resembles a mixture of 5 ozs. carbonate of soda; 1 oz. bi-carbonate of ammonia; 10 ozs. of *alum;* and 8 ozs. arrowroot.

HOSFORD'S (American) is a powder supplied in two packets. One contains an acid phosphate of lime and magnesia, mixed with flour; and the other bi-carbonate of soda with a little chloride of potash.

Best baking powders generally consist of tartaric acid, bicarbonate of soda, and rice flour. Here are a few recipes:—

(1.) A fair average quality would be 6 parts tartaric acid, 8 bicarbonate soda, 1 carb. ammonia, and 12 ground rice.

(2.) 6 parts tartaric acid, 8 bi-carbonate soda, 16 rice flour.

(3.) 20 parts tartaric acid, 27lbs. bicarb. soda, and 53 ground rice.

(4.) 8lbs. tartaric acid, 10lbs. bicarb. soda, 12lbs. rice flour.

(5.) For home use mix ¼lbs. carb. soda with 2½ ozs. tartaric acid or 1lb. cream of tartar, and 3lbs. rice flour; keep in a bottle well corked and dry.

(6.) 9 parts bicarb. soda, 8 parts tartaric acid, 10 parts rice flour.

(7.) 2¾ parts bicarb. soda, ⅓ part bicarb. of ammonia, 4 parts arrowroot.

(8.) 56 parts bicarb. soda, 28 parts tartaric acid, 112 parts potato starch, ⅓ part finely powdered turmeric.

(9.) 112lbs. ground rice, 50lbs. bicarbonate of soda 37½lbs. tartaric acid, and 2½lbs. table salt.

(10.) *A cheap one.*—20lbs. acid phosphate of lime (calcium), 29lbs. bicarbonate of soda, 30lbs. powdered starch; or,

(11.) 28lbs. of rice flour, 1lb. tartaric acid, 2lbs. carbonate of soda, and 2lbs. of finely-ground salt.

(12.) Sir H. Thompson recommends: 2 parts tartaric acid, 3 parts bicarb. soda, and 3 parts arrowroot, mixed and bottled.

(13.) A superior quality.—18 parts cream of tartar, 8 parts carb. soda, and 6 parts ground rice.

The only difficult matter, simple as it seems, in making baking powders is the thorough mixing of the chemicals. It is the main secret. Any one can easily put the ingredients together in the proportion desired, but very few know how to mix them properly, and fewer still know that it is necessary to mix them a long time before using. No baking powder is fit to use until the soda and cream of tartar or tartaric acid are so intimately mixed that there is not a particle of one without a particle of the other. The mixture must be a thorough chemical combination. This is why home-made baking powders, badly mixed and newly made, are disappointing and the commercial article praised.

The baking powders sold nowadays appear to be remarkably free from deleterious ingredients; the only doubtful substance met with being *alum*, employed instead of tartaric acid; and, as the majority of doctors and chemists consider it injurious, it should not be used. Anyone now (1900) selling baking powder containing alum or other injurious ingredient is liable to be fined. (See Food and Drug Act of 1899, Sec. 6; in conjunction with Sec. 3 of the 1875 Act.)

Baking powders may be made up of any materials the manufacturer pleases, so long as there is nothing injurious to health; but, from the foregoing, it will be noticed that tartaric acid and carbonate of soda constitute the chemical base, and that the correct proportions are 6 parts of the former to 8 of the latter, the amount of ground rice, rice flour, etc., may be added to any reasonable extent.

To detect alum: Put two teaspoonfuls of the powder in a glass of cold water. If it does not bubble or simmer it contains alum, and that prevents it.

Gardner's patent "*Rapid*" *Sifter and Mixer*, freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

John May, 114 *Church Street, Croydon*, packs, in various sizes, a baking powder of improved and reliable quality. (See advt. end of book.) It can also be supplied with customer's own name by an arrangement according to the system strongly advocated by Mr. Alderman Ireland, J.P., at the Grocers' Conference, 1899, as a preventative against "cutting." (See extracts from his speech, post free, from John May.)

Other Special Manufacturers.—W. H. Dawson, 66 Finsbury Pavement, London, E.C.—works, Great Yarmouth; The Easteleine Company, Newbury, Berks (see advt., end of book); Morris & Jones, 13 to 19 Sir Thomas Street; R. H. Poole, 126 Witton Street, Northwich, Cheshire; C. Windschuegl & Co. (ingredients for), 1 Leadenhall Street, London, E.C.

Balachong, Balachoug, or **Garum**—A paste or condiment of pounded or bruised small fish, used as a relish; a kind of *Caviare*, almost a necessary of

life with the Malays, Siamese, Burmese, and Cochin-Chinese, who use large quantities of it as a seasoning with their everyday food. The Greeks and Romans called it *Garum*. There are several kinds, but that most in use is made of a species of small shrimp, which is found in enormous numbers on the borders of the sea in that part of the world. The fish is salted and pounded in a mortar, then made up in small packets, and distributed all over the country. Inferior sorts are made of all kinds of small fish, such as prawns, sardines, etc.

Though fetid and offensive to strangers its preparation and distribution give rise to an extensive traffic throughout the East.

Balloon Yeast.—The trade name for one of purest and best yeasts made. Bakers who have not tried it should write to the Irish Distillery Co., Ltd., Connswater, Belfast.

Bamboo.—A kind of giant grass, from most of the tropical countries.

Balata Gum. — See *Naseberries.*

Bambarra Nuts. — See *Ground-nuts.*

Bananas or **Paradise Figs.**—(See also *Plantains.*)—F. *Bananes;* Sw. *Bananastrod.*

They are an important fruit of the banana tree, *Musa paradisidca*, a native of the East Indies. It is a developed *tropical lily*, now flourishing along with other relatives of the *Plantain* (*M. sapientum*) tribe throughout the tropical and sub-tropical regions of the world, and even does well in English hothouses. It is not really a *tree*, but an herbaceous plant of arboreal proportions, and closely resembles the fig tree; the soft spongy stem, although rising 15 feet to 20 feet high, being made up by the union or sheathing of its leaves as they grow. The leaves, of a beautiful emerald green, are from 3 feet to 6 feet long, and 2 feet to 3 feet broad; a kind of grass cloth is often made of them. When the leaves are at full, a large drooping flower-spike shoots out from their midst, and flowers of a rich pink colour appear; the upper or male flowers soon die, and exhibit no fruit, but the lower or female flowers rapidly change into a bunch of oblong shaped fruit. This is about nine months after planting, and for several weeks a certain number of bunches may be gathered almost every week. A "bunch" means the thick stem, around which may hang seven to ten "rings" of fruit in corkscrew fashion. The size, shape, and number of fruit in a bunch vary considerably; a very large bunch may weigh 100lbs. and consist of some 250 fruit, each fruit 4 inches to 12 inches long, by 1 inch to 1¾ inches in diameter, and finger-like or crescent shaped; but the bunches are generally under 50lbs., and perhaps average about 25lbs. each. This handsome and, to the negro, almost invaluable plant is probably the most prolific that grows. It forms one of the principal sources of food for the lower classes in tropical countries, and its productive powers are prodigious. It is said to produce 44 times more by weight than potatoes, and 133 times more than wheat. A single acre may yield 175,000lbs. yearly. No wonder Humboldt said nothing in the world would grow so much food to the acre as the banana. The fresh core yields about 40 per cent. of dry meal, and the ripe fruit is said to contain about 27 per cent. of solid matter. The nutritive value, however, is only minute, being about equal to that of the potato, and slightly inferior to rice.

Indeed, the chemical make-up of bananas and potatoes is strikingly similar, as will be seen from the following table:—

	Bananas	*Potatoe*
Water	75·71	75·77
Carbonaceous matter...	20·13	20·70
Albuminoids	1·71	1·79
Woody fibre	1·74	·75
Ash	·71	·97

If only a cheap practical process could be discovered for manufacturing banana flour, guaranteed against spoiling, an immense impetus to the industry would speedily result.

The young shoots and tops of the stems of the plant yield a juice used as an

astringent, and are also boiled and eaten as a vegetable, and the spongy pith of the stem also, when boiled, forms a nutritious food of a starchy character. In fact, soups, porridge, puddings, bread, cakes, biscuits, preserves, and mock apple sauce are all regularly made from bananas. They contain less water and more nitrogenous matter than most fresh fruits, and if preserved with vinegar, and afterwards pressed and fermented, they furnish a spirituous drink like cider or wine. They may also be converted into yeast.

In India they are only used when ripe, either as raw fruit or cooked in fritters. About 20,000 acres are devoted to banana culture in Jamaica by the smaller cultivators, and the exports from that island amount to some £500,000 a year, nearly all going to the United States. They are considered the best of keepers. The plants also serve as shades for other products. One kind of banana grown in the West Indies and Cuba has a red skin when ripe, but these are nearly all exported from Baracoa to New York.

The Hawaiian Islanders export largely to Canada, as well as to the United States. Large quantities are now being grown, and exported from the New Hebrides to Sydney.

One banana plantation in Cuba covers an area of over fifty square miles, and employs some 3,500 hands, but the luscious, bright, yellow bananas from Jamaica are much preferred to the large red growths of Cuba.

Considered along with the *Plantain* family, the varieties are very numerous, exceeding 150, and their gradations almost imperceptible. In fact, there are almost as many kinds of bananas and plantains as of apples, varying from a foot long to 3 inches or 4 inches, while some have a thickness almost equal to small musk lemons. The more mealy and sugarless kinds are called *Plantains*, and are often very large. These are never eaten raw except when ripe, but when unripe they are boiled and eaten as vegetables, sometimes fried in slices and often made into preserves.

The unripe fruit also is often dried in the oven, and may then be kept for a long time without spoiling. It is usually carried about in this state by travellers and natives, to be eaten in the manner of bread. The chemical reason why the unripe fruit is chosen for this purpose is that, while unripe the fruit is full of starch, and when dried resembles bread.

Bananas have generally spots on the stems with dark purple stripes, and the fruits are smaller and less curved than the plantain. The banana is also much finer and delicate to the taste, and is generally eaten raw. Many strange animals, insects, and reptiles come in banana bunches; snakes a yard long, tarantulas, and spiders of various species have been found in them. A plantation will bear all the year round. In Central America the fruit sells at about 1/- per bunch, whilst the plant itself would be worth ten times that amount to a soap factory, paper mill, or coffee bag manufacturer. The fibre, which extends the whole length of the plant, is capable of being divided into threads of silky fineness, and, with merely drying, is commonly used for shoe-strings, ropes, etc.

The leaf, with its stalk of the toughest and finest threads, serves the native women as an umbrella during the rainy season, also as a carpet to sit upon, or a bed to sleep on. It is curious how these valuable properties of this textile material have been so long overlooked by our manufacturers. Famine is unknown in banana countries.

When ripe, the skin is either red or of a bright yellow colour, but the bunches are mostly picked when green and hung up in a cool place. When the rind, which comes off easily, is removed, there is found a soft pulp like that of a fine pear, or even more luscious to some palates. But the fruit should be *ripe*.

The banana as a fashionable food in England makes comparatively slow progress. As commonly seen, it is rather an unattractive-looking article, and to some people is positively objectionable for its "candle-flavoured-with-weak-

pine-apple" taste. It was only about 1874 that they began to be sold in England, and came from Madeira.

As a medicine, it dispels constipation in children, and for adults has good effects in cases of acute indigestion. Bilious people are advised to eat the banana the first thing in the morning; but for all this, people in this country do not fly to it as a day commencer. So many things, such as salts, etc., have an early morning reputation.

Not everybody knows how to choose bunches of bananas. Look at the thick end of the branch on which they hang—if it be black the fruit will be black in a day or two, and will ripen too fast and rot. In one day they will be musty and scarcely fit to eat. But if the branch be green the bananas will ripen slowly and lusciously, and be of a good flavour. If all the stem be green the bananas will keep a long time, but if half or three parts of the stem be black it shows that its time is shortening. The biggest and handsomest are generally chosen by ignorant purchasers, but the smaller are the sweetest and juiciest, the tiny "Fig" banana being the best of all. The rind should be thin, and there should be no ridges or corners to it, the larger the ridges the coarser the fruit. All bananas contain starch while green, which upon ripening changes into sugar. They are therefore best when just turning yellow but still streaked with green. This handsome and valuable plant is rarely found wild, although some have been found in Ceylon, Cochin China, and the Philippines; these, of course, have seeds, but are much inferior to the long and seedless cultivated varieties. The banana, however, requires very little cultivation, all that is necessary being to remove the suckers, and plant these at convenient distances. They grow rapidly, and in ten or eleven months bear fruit, and afterwards continue to yield crops every six months for many years.

In Dutch Guiana banana trees are planted as a shade to the young cocoa trees, but as soon as these latter can bear the sun the banana is removed.

Two varieties of banana are generally grown in Madeira, viz., the dwarf and the "silver."

The dwarf (*banana aña*), or Chinese banana, is the kind mostly exported from there, the fruit being much larger and the bunches much heavier than the "silver" variety. The latter, however, is of a beautiful bright golden-yellow colour without any of the dark brown patches which usually disfigure the "dwarf" when ripe, is also much more delicate in flavour, although only half the size, but it is seldom exported.

Those who have once tasted the silver variety seldom use the dwarf, except for cooking.

Madeira bananas are mostly grown on the south side of the island. The season lasts all the year round, although the fruit is at its best from July to December; but the largest export is in winter, when fresh fruit is scarce in England.

Usually cut and packed while the fruit is green, it sustains very little damage in transit, and ripens by degrees.

Packed in large rough wooden crates, holding a dozen or more bunches, between each of which straw is placed to keep them firm and prevent their rubbing one against another. Another method is to pack in baskets made of a coarse native broom, one bunch in each basket, with straw or bracken leaves placed round them to ensure safety in transit.

The island of Grand Canary, however, probably supplies the most to this country, although one day further from England, and certainly occupies the first place as regards cultivation. The crop is ready 18 months after planting; there are usually 1,000 to 1,200 plants to the acre, and over 150 bananas to the plant with two harvests a year.

The exporting merchant commonly secures by contract the yearly crops of several growers, taking all fruits over a certain size.

In 1891 the price was about 1/10 per bunch, and in 1892 only 1/6, but the demand having increased, much higher rates now prevail.

The exporter cuts, packs, and removes the fruit as he pleases, usually wrapping the bunches in wood shavings and banana leaves, and packing in baskets.

When it is considered that each bunch contains 150 to 300 fruits or "fingers," and that many are retailed in England at a penny each, there seems a fair margin of profit for somebody.

When very green the bananas should be hung up in a warm room a day or two to ripen.

Grocers often miss profits by the way they display these fruit. They often deter purchasers by showing the worst sides of the bunches; for the average buyer is not attracted to bad-looking fruit by an idea that it is better than it looks. The best plan is to take the bunch, cut from it all the small and bad fingers, and place these in a separate heap to sell cheap. Then cut off the moderately good stock, and turn these best side up for sale at a better price. This leaves all the prime fruit, which will fetch a high price. Customers should always be allowed such a choice, and each may thus be satisfied.

Importers and Merchants.—J. Agate, 25 Wellington Street, Covent Garden, London, W.C.; Elder Dempster & Co., 20 Old Haymarket, Liverpool, and 46 Long Acre, London.

Banana Essence. — Usually made up of equal parts of butyric ether and amyl-acetic ether, dissolved in about 5 parts of alcohol.

Banana Flour or **Plantain Meal.** —A very nice flour for confectioners' use, and easily digested. It is made by desiccating the bananas or plantain fruits after depriving them of their sheath and then reducing them to powder. Mr. Stanley, the African explorer, highly recommends its use. It is used as ordinary flour for custards, puddings, blancmange, and is very nutritious as a food for infants and invalids.

Special Importers.—The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Banbury Cakes. — Banbury was famous for its cheese and cakes as early as 1586 (see First Edition of "Camden's Brittania"). The modern cakes are chiefly composed of a mince called "Banbury meat" enclosed in rich pastry, and then baked. They are usually cut either into oval or oblong form, almost pointed at each end, and are eaten cold. They were highly popular in the days of Ben Jonson (see his play "Bartholomew Fair"), and it is recorded that the first inventor was a man named White, who was such a strict Puritan that he "hung his cat on a Monday for killing a mouse on a Sunday." These cakes are now very similar to Eccles Cakes.

Take 1½lbs. of flour, 7 well-beaten eggs, 1 teaspoonful of volatile salts dissolved in milk, 1½lbs. of fine sifted sugar, 1½lbs. of currants. Mix the eggs with the sugar and whisk well together, then add the other ingredients, mould, and after brushing them over with the froth of eggs or other substitute, bake well on a flat tin in a hot oven.

Banbury Cheese. — A very rich dry sort with a thick rind, made at Banbury, in North Oxfordshire.

Bandoline.—Also known as *Fixature* or *Eau Collante*, etc. A kind of pomade consisting of any of the simple vegetable mucilages, combined with a little spirit to preserve it, and with a little perfume to render it more agreeable. It is often made by dissolving in following proportions, say 1½ ozs. pale gum-arabic in 3 fluid ozs. of pure water, and adding 2 fluid ozs. of rose-water. Some are made by boiling Iceland or Irish moss in water, then straining and perfuming the fluid; or by boiling for five minutes a tablespoonful of flax seed in 1¾ pints of water. They are all used for stiffening the hair, and fixing curls as desired.

Baneberries. — The berries of the Herb Christopher (*Actæ spicata*), a kind of crowfoot, native of the north-west of Yorkshire, where it grows wild. The berries are poisonous, but with alum they yield a dye similar to that of cochineal.

Bangalore Apples. — A small but very nice Indian variety about the size of billiard balls, and excellent when stewed.

Bannock Cakes. — In Scotland and the northern counties of England, *Bannocks* are thick flat round cakes made either of oat, rye, barley, or pea meal, baked on an iron plate over the fire, or on the hot hearth.

Barbary Sugar.—The finest sugar, which was formerly supposed to be brought from Barbary, before the trade of the West Indies was fully established.

Barbary Tea.—This consists of the leaves of the common box-thorn genus (*Lycium barbarum*), spiny shrubs, also known as the Barbary tea-plant and Duke of Argyll's tea-tree, etc.

It is said to yield an excellent beverage.

Barbe de Capucin. — See *Salad plants.*

Barbera Wine. — One of the most esteemed red wines of Italy.

Barberries. — The barberry or *Thorny-box* tree is a hardy perennial shrub, and is common in woods and hedges all over Great Britain. It flowers in May or June, and when in bloom it emits a powerful odour.

The fruit, *Berberis vulgaris*, which ripens in bunches in September or October, is very acid and of astringent nature, but the juice when diluted with water is very grateful to the taste—cooling, and of great benefit to patients suffering from fever.

There are several varieties—the red-berried (with stones), the black sweet, the purple, and the white. The seedless, *B. vulgaris asperma*, is mostly preferred for preserving purposes.

Formerly, barberries were held in great esteem by those acquainted with their virtues. The leaves, in salad, are applied for the same purpose as sorrel, and the fruit makes an excellent pickle, as well as a marmalade, jam, and jelly. Barberry Drops or French Drops, as they used to be called, also Barberry Comfits, made of sugar, flour, and gum, were far more commonly known years ago than they are now.

Barcelona Nuts.—(See also *Nuts.*) —The best and the most important variety of the common hazel nut, cultivated chiefly in Spain, where some whole districts are covered with nut trees, *Corylus avelland*, var. *Barcelonica.* They appear to be synonymous with our *Cob-nuts*—the husks shorter than the nuts. When gathered they are carefully dried in kilns and sifted into different sizes before exportation. Although popularly called *Barcelonas*, they are nearly all shipped from Tarragona, a more southerly port; upwards of 200,000 bushels are imported into England yearly. A bag of Barcelona nuts weighs about 128lbs. or 168lbs. barrel measure. They are usually cheapest to buy in England about the month of October, the new crop nearly always arriving in time for Halloweve (October 31st), which in many districts is the principal, if not the only, time there is a brisk demand; but if fresh nuts are late in arriving or are very dear, they are sometimes mixed with or substituted by old nuts, also with an inferior kind of nut, and this discourages the consumption. Spanish nuts are now imported in barrel-sacks, and the price is about 24/- per barrel-sack.

Importers.—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Barclay's Pills. — The Rev. D. Barclay's Antibilious Pills are said to be made from the following:—2 dr. extract of colocynth; 2½ dr. soap of jalap; 3 dr. extract of guaiacum wood; 8 grains tartar emetic; and 4 drops each of oil of juniper, carraway, and rosemary. The whole well mixed and divided into 4-grain pills.

Barilla. — (See *Soda.*)—The name of an impure soda, as imported from Spain and the Levant.

Barley. —F. *Orge;* Ger. *Gerstengraupen;* D. *Rijg;* It. *Orzo;* Sp. *Cebado;* L. *Ordeum;* W. *Haidd, Barlys.*

A hardy cereal, *Hordeum*, which extends over a wider climatic range than any of the other sorts of grain, and is perhaps the most ancient of the cultivated seed foods. It is grown extensively in the Midland and Northern counties of England and in Scotland, particularly

in the Lothians. Of late years large quantities have been imported from the Black Sea and other foreign countries, but these are much inferior for domestic purposes to the fine English and Scotch growths. Very little barley is grown in America, but in Spain and Italy two crops are obtained in one year. In England barley is used to fatten cattle, pigs, and poultry, or converted into malt for making beer, ale, porter, and British spirits; or partly deprived of its husky covering by a rasping or paring process in a mill, and so made into human food as *Scotch*, *Pot*, or *Hulled barley*, or when steamed, dried, and further rounded, and polished in the mill, *Pearl barley*—the latter itself being sometimes ground into a fine powder and called *Patent barley*.

There are several species of barley, but, like certain other plants that have been long in cultivation and been so altered thereby, it is not known what was the original wild form. *Hordeum vulgare* has around the rachis the grain in *four* rows. The *H. hexastichum*, or *six*-rowed, is the *bear* or *bigg*, grown as a winter crop in the North of Scotland; and *H. distichum* in *two* rows, which is the kind most commonly cultivated for malting. The lower part of the ear in the varieties ranked under *H. vulgare* is, however, often six-rowed, and only the upper part four-rowed, for in rich soils a tendency to resume the *six*-rowed is often noticed. A kind with naked seeds, called *Siberian barley* (*H. Coeleste*), is cultivated in some parts, but falls from the straw too freely and is wasteful. In England and Scotland barley generally follows turnips as a spring crop, but in Ireland it is usually sown as a winter crop. The word barley is from the old English *Boerlie*, which is from the Anglo-Saxon *Bere*.

About ten million quarters are grown in the United Kingdom, and about eight millions more imported yearly, Russia sending about five millions and Turkey two millions.

A bushel of barley weighs 50 to 54lbs., and an acre produces 28 to 40 bushels.

A barley-corn is a corn or single grain of barley, the third part of an inch; hence originated our measures of length.

Apply to Keen Robinson & Co. (manufacturers of *Robinson's Patent Barley*, in packets and tins), Garlick Hill, London, E.C.

Barley-bree.—A liquor made in Scotland from barley.

Barley-meal.—Is the grain ground whole. It is darker in colour but lighter in body than wheatmeal, and in 100 parts it has 79 of starch, 6 of gluten, 7 of saccharine matter, and 8 of husk.

It is cheaper, lighter in body, and more easily digested, but not so nourishing as that made of wheat. Barley-meal in the time of Charles I. almost entirely took the place of wheat as the food of the common people, especially in the north of England; and in some parts of Northern Europe it is still largely used in bread-making, and, mixed with a little *corn-flour*, it yields a very nice white bread.

Wheat-flour is often mixed with *barley-flour*, the latter being supposed to counteract the constipating effects of the former.

Barley-meal is sometimes adulterated with oat husks, apparently to increase the bulk.

Barley Sugar.—F. *Sucre d'Orge*.

A brittle confection of sugar, boiled rapidly and drawn into long yellow strips, more or less transparent and generally flavoured with lemon.

Originally it used to be extracted from an acid decoction of barley or barley-water, but this is rarely attended to nowadays.

The best white sugar, often mixed with glucose, is in the ordinary manner dissolved, boiled, and skimmed to the "hard crack," then poured ¼ inch thick on a slab, coloured yellow with saffron water, and while warm cut in strips ½ inch wide and curled by holding one end in each hand and twisting it reverse ways.

Barley-Water.—A mucilaginous decoction of Pearl or Scotch barley, and is considered a soft, lubricating, and invigorating drink—especially for invalids.

Take 2 oz. of pearl barley, wash it well, and boil for 10 minutes in a little water to clear it; when drained, put to it five pints of boiling water, and let it boil till reduced to one-half. Then strain for use.

Barley Wine. — G. *Malten-Weine.* A new wine, representing port, made from highly-fermented barley. First discovered by Pasteur, but first manufactured by Mr. Hansen, a Danish scientist; and now made and exploited by a factory at Wandsbek, near Hamburg. The barley is malted and carried to the point of fermentation, when lactic acid and vinous ferments are introduced into it, and it is then treated by sundry variations of temperature. When fermentation is completed, the new wine is put into huge vats and then into casks, where it is subjected to artificial maturing, by being raised to a high temperature. Barley wine is noted for its large percentage of alcohol, derived entirely from fermentation and not from added alcohol.

Barm.—See *Yeast.*

Barsac Wine.—A white French wine, known as one of the *Sauternes*, produced in the Bordeaux district.

Bartlett Pears. — A very popular growth of pears in the United States, originally known in England as *Williams's*, and in France as *Bon Chrétien.*

Barytes (pr. *bright' tees*). — F. *Barytes;* G. *Schwerspath;* Sp. *Barita.* The native sulphate of barium; a common name for the mineral *barite* or *heavy spar.* This ponderous earth is mined, ground in a mill, and often used to adulterate white lead, to weight paper, etc.

For prices, etc., apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Basil or **Sweet Basil.** — F. *Basilic;* It. *Basilico.*

This garden herb (*O. basilicum*) is a native of the East Indies. It is highly aromatic, its perfume greatly resembling that of cloves. Not much used in England, but in France its leaves are in great favour with cooks for flavouring soups, salads, etc.

There are several other kinds of basil, all natives of warm climates, but only the *sweet* variety is valued.

Bass Brooms.—The bass broom, made from the well-known fibre of the *Piassaba* plant from Brazil, *Leopoldinia piasaba* (Para bass), and *Attalea funifera* (Bahia bass), commonly called "bent," was discovered in a manner that may be interesting. (This must not be confused with the Russian bass, from which bass, or bast, mats are made; that is from the inner bark of trees, and is largely used by gardeners for covering seed beds, also by furniture packers.) The *bass broom* industry has only grown up during the present century. Bent was formerly used as dunnage or stowage. Large quantities were frequently thrown upon the quays at Liverpool, and there remained, as the coarse grass was supposed to be of no further use. One morning a brushmaker, who was rather out of sorts through some indulgence in the cup that inebriates, strolled along the quay in the vain endeavour to get rid of a violent headache. For the purpose of whiling away the time he picked up a few pieces of the fibre, and after handling it for a moment, it occurred to him that it might be utilised for the coarser kind of brushes. He took some of the "bent" home and made a brush of it, which was of a class that was eminently suited to rough work. Being joined in the work by another man, for a time they realised large profits; but it soon became known that "bent" had a commercial value, and a price was placed upon it. Mr. Robottom afterwards travelled to many large towns in Europe and Amercia, buying and selling the article, and so introduced the bass broom industry into many countries. The Danes in Copenhagen were the first to go heavily into the making of these brooms, and in London the business was first taken up by a Mr. Hanks, in Kent Street, now Tabard Street. (See also *Brooms, Brushes,* etc.)

Bastards.—See *Cucumbers.*

Bastard Sugar. — A coarse kind of crusted loaf sugar, made from the syrups and other refuse of refined sugar, or from the impure or damaged sugar resulting from the heat and chemicals used, particularly from the impure crust which forms on the upper surface of the pans, and known as pan-sugar.

Baster's Soojee. — A kind of semolina; said to be a mixture of ordinary wheat-flour and sugar.

Batatas.—See *Sweet Potatoes.*

Bath or **Bristol Bricks.** — F. *Briques à couteaux;* W. *Bricsen felen.* (Also known as *Brick-dust.*)

These are friable artificial stones of yellow colour, composed of a fine calcareous or silicious sand or slime deposited in the River Parret, near Bridgwater, in Somersetshire, and within an area of about three miles, where the salt water meets the fresh.

The slimy mud is collected and dried, then ground and worked up with water in pug mills, then hand moulded into bricks, redried in the sun, and burnt in a kiln; finally, when cooled, each brick is rubbed somewhat smooth on a stone by women. They are mostly prepared at Bridgwater and are used for cleaning and polishing metallic utensils, knives, etc. *Flanders brick* is a similar article, but Bath *stone* is quite different, and used for building purposes.

Bath Chaps.—Small pigs' cheeks, chops, chaps, or jowls, cured or smoked for cooking whole. The two upper jaws, being separated into triangular forms, are retailed at 3d. to 4d. per lb. The two lower jaws also separated, being more meaty, and containing the tongue, are retailed at 7d. to 9d. per lb.

Cooks often spoil these; tell them to lay the "chap" in a pail of cold water, skin downwards, and let it remain one night. Scrub the chap with a small brush to cleanse it; put it into plenty of cold water to boil, make it come to a boil quickly, and then draw the pan aside to simmer two or three hours. Then skin and garnish with any boiled green vegetable.

Bath Cheese.—A noted kind of soft, creamy cheese.

Bath Oliver Biscuits.—Dr. Oliver, M.D., Bath, who died in 1764, was the inventor of these. Prior to his death he called to him his favourite coachman and said: "My good Atkins, I wish to put you in the way of making a livelihood when I am gone. I give you the recipe to make my biscuits; I give you a supply of ten sacks of finest wheaten flour and £100." Atkins took a small shop in Green Street, Bath. There he established himself as the sole proprietor and maker of Oliver's biscuits. He made a large fortune out of the biscuits, and was succeeded by Norris, Carter, Munday, Ashman, and James Fortt; the business is still carried on by the last-named, on the same premises in which these excellent biscuits have been made for the past 136 years. There are now several *imitation* Oliver biscuits made by other firms in Bath and elsewhere, but the "ORIGINAL" Bath Oliver Biscuits can only be obtained of James Fortt, 13 Green Street, Bath. They require very great care in their manufacture, and should be crisp, of a fine texture. With either wine or cheese, they make a delicate diet, are easily digested, and sell well in all high-class neighbourhoods. (See advt. at end of book.)

Bath Pipe, Lozenges, etc.—Consist of a paste made in the following proportions:—1 oz. of gum arabic, 1½ oz. of extract of liquorice, and 1lb. of white sugar, dissolved in warm water.

Batons. — A French word for sticks, such as "Chocolate Batons"—*i.e.*, chocolate sticks, etc.

Bavarian Beer. — See *Lager Beer.*

Bavarian Cheese. — These very much resemble Swiss makes, and are often sold as such.

Bay Leaves. — The leaves of a species of laurel, *Laurus nobilis,* or sweet-bay tree, generally a mere bush with large, tough, and shiny green leaves, which have a sweetish-bitter and aromatic taste, and a fragrant aromatic odour.

They are said to be narcotic and stimulant, and are used as a flavouring ingredient in many culinary processes; also in medicine and confectionery. Often found adhering to the sticks of Spanish liquorice, partly to prevent the sticks uniting to each other, but chiefly to preserve them from the ravages of small white destructive grubs or maggots, which are apt to bore full of holes the hardest liquorice juice. They are also packed among figs for the like purpose. In ancient times laurel or bay leaves were used to form wreaths or garlands to adorn the brows of victors. The term "bay," which is also applied to the plant, appears to be derived from the Latin *Bacca*, a berry, and the fruits are commonly known as *Bay berries*. (See also *Christmas*.)

Bay Rum or **Bay Water.**—(The druggists usually spell this word "*Rhum.*") It is a spirituous perfume, like Eau de Cologne, and is used as a highly-valued head-wash, pleasant, cooling, and cleansing, promoting also the growth of the hair, darkening the colour, and preventing *dandriff*.

The genuine article is prepared only in the West Indies and Venezuela from the oil of myrcia, distilled from the leaves of the *Laurus acris*, or wild clove tree, and not from *Laurus nobilis*, as often supposed.

In Dominica it is manufactured from the dried leaves of *Pimenta acris* by distillation, and in a very simple manner. The leaves are picked from the trees, dried, placed in the retort—which is then filled with water—and subjected to the process of distillation. The vapour is then condensed in the usual way, and forms what is known as "bay-oil," a very small quantity of which is required for each puncheon of rum. The manufacture of bay-rum is carried on at the northern end of Grenada, and proves a very lucrative business to those engaged in it, as the plants are plentiful in the district. The following is an estimate of rum, etc., required:—

	£	s.	d.
1 pun. rum—100 gals. about 18 to 19 proof, say, at 2/- per gal.	10	0	0
Empty puncheon	1	0	0
1½-pint bot. bay-oil pure to a pun. of rum	0	16	8
	11	16	8

The rum must be of the strength of 18 to 19 proof or the oil will not amalgamate properly. The *Pimenta acris* (more commonly, *Myrcia acris*) is the tree known in Jamaica as the wild cinnamon.

Inferior articles are sometimes prepared from the oil of bay, but these are very deficient in fragrance.

A very fair Bay Rum may, however, be produced as follows:—¾ oz. oil of bay, ¼ oz. oil of orange, 3 pts. of alcohol, 3 pts. of water, and a little precipitated Phos. Calcium. Mix the oils and alcohol, add the calcium and shake, then add water and shake thoroughly and filter. Colour with 90 proof rectified Jamaica Rum, or with a little caramel.

Bay-rum is also used as a refreshing perfume in faintness, or to sprinkle about sick-rooms.

Bay Salt or **Sea Salt.**—See also *Salt* and *Rock Salt*.

The salt obtained from sea-water by evaporation.

In hot climates this is done by the heat of the sun, the water being first retained in shallow square pools or "brine-pits" dug for the purpose. The crystals of this kind of salt are of more perfect form than in any other; also purer, from the greater slowness of the process.

Most of the salt in France is obtained in this way, and particularly on the coast between the Loire and the Gironde estuaries, also on the Mediterranean coast, but there are mines as well; the towns of *Salins*, and *Sous-les-Saunier* in the Jura Department, taking their names from salt mines.

The finest salt is colourless and transparent, with a specific gravity of about 1·125. Considerable quantities are imported into the United Kingdom from Portugal.

In the State of Colima, Mexico, there is an immense shallow lagoon called the *Laguna de Cuyntlan*, which stretches 20

miles inland from Manzanillo, on the Pacific coast. During the rainy season this lagoon is full of water, covering a large extent of low muddy ground. In the dry season hundreds of acres dry up, and are then found covered with a crust of fine salt crystals. The ground, earth, and salt together, to a depth of an inch or two, is scraped in heaps by men, women, and children, who carry it to a filter constructed of different layers of brushwood, branches of trees, etc., four to six feet thick, on the top of which the mass of salt and earth is thrown. Water is then poured over it to dissolve the salt, and it flows slowly down into a deep trench below the filter, while the earthy matter remains in the brushwork. The purified brine is then taken and poured into shallow basins, four to six inches deep, constructed of common mortar for evaporation by the tropical sun, and during this process the white crystals first appear on the top surface, but finally sink to the bottom. The crystallisation having been completed, the dry white salt is scraped together and put into sacks for market. Thousands of labourers are employed on this salt field during some three months, say, April to July.

Bean Curd. — See *Torfu* and *Soy*.

Beans. — Da. *Böuner;* Du. *Boonem;* F. *Fèves;* Ger. *Bohnem;* It. *Fave;* Port. *Favas;* Rus. *Boobii;* Sp. *Nabu, Habas;* Sw. *Bönor;* W. *Ffa.*

These well-known pulse (*Vicia faba*), largely cultivated both in fields and gardens, are to the farmer of peculiar importance, inasmuch as they grow best on strong, clayey lands, which would otherwise often lie fallow. There are at least twenty-five species of beans, seven of which are natives of Britain. Of the Windsor, Field, or Broad Beans may be noted: The early *Mazagan*, from a Portuguese settlement of that name on the coast of Africa, and whence the best seed is obtained; the *Long Pod*, very popular for its usefulness and fertility; the *Windsor*, *Green Windsor*, are highly esteemed for table use. The *white* or *red blossomed Dwarf fan*, or cluster-bean, is an early kind, but mostly grown for curiosity; *dwarf* red is a very early kind and highly productive, but perhaps the smallest kind grown. Beans grow admirably in Egypt, where their blossoms are much more odoriferous than in Europe. (Haricot Beans, Scarlet Runners, *French* or *Kidney Beans* are described under their own name.) The outer skin or covering with which the inner lobes of beans are enveloped is very tough and indigestible, and should not be eaten by delicate persons or those of sedentary habits; beans and peas at all times being apt to produce flatulence, indigestion, and heartburn. To shell beans easily, pour upon the pods a quantity of scalding water, and the beans will slip very easily from the pod.

Florida Velvet Beans.—These are a new and very prolific and vigorous variety, which give in leaf, vine, and fruit, from four to five tons to the acre and from twenty to thirty bushels of shelled beans. Animals enjoy both the leaves and the dried bean. The plant also makes a very handsome trellis climber, but requires rich soil and a climate rather warmer than most parts of England.

Bearberries.— Latin *Uva-Ursi*, from Uva (berry) and Ursas (bear). These red berries are the fruit of a species of the Erica family. They grow in bunches, and have been supposed to have been either a food for bears, or, being found in wild mountainous districts, the name may simply indicate the plant had the same habitation as the bear. Both the berries and leaves have valuable astringent properties used in medicine.

Beaufins. —See *Norfolk Biffins* or *Dried apples.*

Beaune Wine. — This takes its name from the town of Beaune (Cote d'Or), in the Burgundy district. The Beaune Hospital, which owns some excellent vine lands, sells its wine by auction, and the price obtained serves as a basis during the year for all other wine growers in the neighbourhood. (See *Burgundy.*)

Bechamel Sauce.—A white sauce of French origin, made chiefly from

arrowroot, cream or milk, eggs, etc., for use with fowl and similar white meats.

Beche de Mer Soup. — See *Trepang*.

Bedda Nuts.—A trade name for the fruit of *Terminalia bellerica*.

Beech Nut Oil. — F. *Huile de Faine*.

Obtained chiefly in France from beech nuts, *Fagus sylvatica*, after they have been shelled and pounded. The refuse after expressure of the oil is used as fuel. Beech oil is used for food and also for burning. In plentiful years a large quantity of this oil is made in Southern Germany. The nuts contain only about 22 per cent. of oil, yet the ease with which they are obtained, and the fact that the only expense is the pressing, have recently made its production a favourite industry.

The nuts themselves are sometimes roasted and eaten like chestnuts, also powdered and mixed with other meal for making into bread.

Beecham's Pills.—See also *Patent Medicines*.

Many examinations of these have shown their composition to be aloes and ginger, mixed with a little soap.

How the proprietor makes out that a 1½d. box is "worth a guinea" is a mystery. The ingredients might be bought for a penny.

Beef a la Mode.—F. *Bœuf à la mode*; G. *Gedämpfte Ochsenrippe*.

A sort of thick gravy soup or "*bouilli*." Proper "*Bœuf à la mode*" is not a mere rich stew such as is sold daily under that name in London cook-shops.

It should be prepared by *slowly simmering* meat for a long time. This is the essential point, and the gravy ought to be red in colour, rather gelatinous in consistence, and full of the agreeable flavour and nutritive matter of both meat and vegetables, which is the distinctive mark of the dish.

Take of rump, sirloin, shin, or rib of beef, say about 12lbs. Lard it through with 10 or 12 long pieces of fat bacon; put it into an earthen pan with calf's foot, 4 onions, 2 carrots (sliced), a bunch of parsley, 2 bay leaves, 2 sprigs of thyme, 2 cloves, ½ teaspoonful of pepper, 1 do. of salt, 4 wineglasses of sherry, 4 do. of water, and 1lb. of streaky bacon (cut into small squares); place on the cover; make it airtight round the edges with a little flour paste, and expose it in a moderate oven for about four hours. Dish up with the vegetables and bacon placed tastefully round it, the gravy (skimmed) being poured over all. Or it may be eaten cold, in which case the pan should not be opened until the whole is quite cold (*Soyer*).

Beef Chilled. — The annual consumption of flesh meat in England is about 87lbs. per head of population, and about 27lbs. of this comes from abroad. The fresh (chilled) beef exported from the United States amounts to about 300 million pounds a year, and many enterprising grocers with advanced "store" proclivities are now assisting in its distribution.

"Chilled" meat is very different from frozen meat, for it is never frozen. The principal firms engaged in the chilled meat trade are located at Chicago, where they have extensive works and the most elaborate plant and appliances for carrying on the business. The cattle are purchased from practically every State, and sent to Chicago. Then those which are selected to cross the Atlantic alive are forwarded to New York and Boston for shipment, while the others, the well-matured animals, are consigned to the slaughter-house. They are killed, and the beef is packed and conveyed in cold stores by special train to New York and Boston, where it is transferred to some of the best and fastest liners afloat. These vessels are provided with exceptional facilities for carrying the meat. In less than a fortnight from the day the animals are killed the beef is offered for sale in the English markets. It is richer than the flesh of the animals killed at Birkenhead and Deptford, because it suffers no deterioration during the voyage, and keeping it in the chilled state has the effect of making it tender and improving

the flavour and quality. Indeed, in this respect it is said to compare very favourably with English meat, which is rarely hung long enough to perfect it for the dinner-table. Chilled meat may be recognised by its colour, which is hardly so bright as in English meat. This is due to the fact that it has been kept longer, but when placed side by side with a joint of English meat hung in the larder for a few days, the difference is scarcely apparent. At first the British public looked askance at the foreign meat, but it gradually forced its way into popular favour, and now between 20,000 and 30,000 quarters of chilled beef are sold in England every week. The sales in the wholesale market vary considerably.

The price generally rules about the same as for English beef, but it has been slightly higher. The wholesale price of chilled beef at the present time ranges from 3d. to 4d. per lb. for fore-quarters, and from 5d. to 6d. per lb. for hind-quarters; while the retail price varies between 3d. and 7d. per lb. for joints from the fore-quarters, and 4d. to 10d. per lb. for cuts from the hind-quarters.

The great Chicago packing houses get a great deal more money from the by-products incidental to the killing of a steer than the meat sells for. On the average the meat and its compounds bring 40 dollars, while the by-products bring in at wholesale 55 dollars. The latter sum is roughly made up as follows:—Hide, horns, hoofs, and hair, 25 dollars; fats, blood, sinews, and bones, 15 dollars; miscellaneous and other wastes, 15 dollars.

It is only in the large and well-appointed slaughter-houses that the full value of the animals dealt with can be realised, and there become factories for a great many products, besides finding the proper and most profitable markets for each of the raw products into which they separate the animals. Nothing is allowed to go to waste, and ten years ago one of the largest butchers in the city declared that the Chicago packers were paying the entire cost of slaughtering cattle out of what the butchers here were paying to have carted away. Hides, horns, hoofs, and hair have had their markets for many years, and their value increases steadily. This is particularly true of horns, for the practice of dehorning cattle has become so general that in one great Chicago packing house it was found during a two-year count that the returns only showed one horn to every three bullocks. Horns are now worth about 150 dollars a ton. The hides go to the tanner, the hair for mixing in mortar. The tails do not go with the hides. Down at the tip is some long hair, and this is said to be turned into curled hair for upholstering.

If the hoofs are pure white they have a peculiar value. They are sent to China for jewellery making. Those which are striped, black or damaged, go into the kettle to be boiled for glue, and the residue made into hoof meal, a valuable fertiliser. In fact, everything which is not used for other purposes is at last turned into some form of fertiliser, even to the tankage water in which the coarsest of the refuse is boiled to extract its fats. The coarse bones are either carbonised and sold for sugar refiners' use or turned into fertilisers, and the blood is mostly dried and turned into another aid to agriculture. Some of the blood is sold in liquid form to sugar refiners, but not a great deal. The white bones, suitable for knife handles and such purposes, bring from 70 dollars to 90 dollars a ton, and go mostly to Germany.

The main parts of the animal as they are sent to market are all carefully trimmed, but there is no piece of good meat but has its market. Tongues and tails are regular articles of commerce, and even the meat from the cheeks is added to the supply for sausages, and the lips are cut off and pickled. Each character of fat is separated from the others, and finally these are marketed in the various forms of neat's foot oil, oleo oil, tallow and stearine and oleo-margarine. Before the horns are sold the pith is extracted from them, and the finest grade of gelatine is obtained from the pith.

The sinews are all separated, to be used for glue stock; the bladders are sold for holding snuff, and the greater part of the intestines are used for sausage casings. Parts of these have, however, a special use and value, and are sold separately to be made into goldbeaters' skin. The lining of the windpipe is also of particular value, being used for a fancy sausage casing, and also as a lining for pipes through which beer is passed in breweries. Beef extracts, pepsine, and many other things are made in some of the biggest houses.

A new use has recently been discovered for the contents of the paunch, which until lately had to be thrown away. It has been discovered that a good quality of cardboard can be made of it, and it is now being saved for that purpose. Of course, the large receipts from these by-products are not all profit, but there is a manufacturer's profit made out of each one of them which aggregates a handsome sum, and all of this helps to keep down the price of the fresh meats to the consumer.

Beef Essences. — See also *Meat Extracts*, *Juices*, etc.

The principle on which these are prepared may be illustrated as follows:— Place 1lb. beef chopped small and ½ pint of water in a bottle, which they only half fill; agitate them violently for half an hour; then empty on a sieve, and receive the liquid in a jug; next, boil the undissolved portion in a pint of water for twenty minutes and strain; mix this liquor with that from the jug and evaporate to the consistence of a thin syrup, adding spice, salt, etc., to taste, and pour while hot into dry bottles, jars, or tins, which must be hermetically closed, and stowed in a cool place; or finely minced lean beef is placed in water heated to 60°C. and well stirred for ten minutes, a large portion of the albumen and albuminoids, together with some of the extractives, pass into solution, whilst the myosin and much of the gelatine is left unchanged. The result is different if boiling water be used, coagulation and fixation of the albumen of the muscle taking place, the latter becoming hardened. If the boiling be prolonged for several hours, gelatine, extractives, and salts pass into solution, leaving behind the insoluble myosin and albumen. It will, therefore, be seen that a proteid or albuminous beef-tea fairly rich in nitrogen can be prepared by infusing beef below the coagulating point of albumen, but, on the other hand, boiling the beef merely yields a solution of the extractives, accompanied by some gelatine.

Most of the preparations are, however, of comparatively little value as foods, but are rather to be regarded as flavouring and stimulating substances. Many poor persons in times of sickness are misled by the term "Essence," or Extract, and imagine they are buying a strengthening food, but the hard-earned money is often wasted and the sick person starved.

What is wanted is a genuine liquid beef of pleasant flavour, which can be guaranteed to contain the whole of the proteids.

The extravagant and impossible claims put forward by some makers are simply ridiculous in face of the fact that the most concentrated meat cannot represent more than five times its weight of lean muscle.

One of the most popular and expensive foods yields on examination ·12 per cent. of albumen, 57 per cent. of solids, boric acid being used as a preservative. It appears to be merely compounded of a meat extract and a little added albumen. As a nutrient this article is really of no value, for an entire bottle only contains *one grain* of albumen.

Another food of the same class is merely a "doctored" blood, the corpuscles being evident under the microscope, whilst on heating a thick coagulum is formed. One hundred parts give 35 of solids, of which 12·7 are found to be coagulable matter composed of a mixture of albumen and hæmatin. This preparation is evidently made by whipping ox-blood to remove fibrin and then merely adding salt and boric acid as preservatives. However, being rich in serum albumen, it is not a bad nutrient.

Special Manufacturers.—Armour & Co., Chicago, U.S.A. (London address: 8 and 9 King Street, West Smithfield, London, E.C.), manufacturers of *Extract of Beef* (solid) and "Vigoral" (liquid). Both these are prepared from pure beef and largely used in soup making, bouillon, and general cookery. See also "*Bovril*" and *Liebig's Extract of Meat.*

Beef Marrow Soap. — A soap made of caustic soda lye and beef marrow heated until it becomes soluble in water, and then diluted with boiling water and brine.

Beef (Potted).—The ordinary kinds sold at pork shops, etc., are generally made of two parts Australian or American meat, with one part of any scrap meat. The latter is first boiled until well cooked, when the former is put in the boiler with it for a few minutes. A pound of gelatine is next dissolved in a quart of the liquor in which the meat has been boiled, and after the gelatine has dissolved, the whole of the meat, gelatine, with ground pepper, cloves, cayenne, salt, &c., as seasoning, is chopped as fine as possible, and sometimes coloured with red earths, &c. It is afterwards pressed into cold moulds.

Beef (Spiced). — Spiced beef is merely salted beef, when spices, usually black pepper and allspice, have been added to the salt, &c., used in curing it.

Beef Suet.—See *Hugon's* "*Atora*" *Refined Beef Suet.*

Beef Tea Cartridges. — Sold in 6d. boxes, five in a box, for travellers. One cartridge makes one cup.

Beef (Tinned). — F. *Viande en conserve*; G. *Buchsen fleische*; Sp. & Port. *Carne en conserva.* (See also *Tinned Meats.*)

Most of the tinned beef sold in the shops comes from the United States, and in 1896 nearly 39 million pounds were imported from that country.

The number of cattle slain in America, chiefly at Chicago and Kansas, each year for salting and canning is about 200,000, mostly raised in Wyoming, Montana, North Dakota and other States, west of the Mississippi, which also supply England yearly with over 300,000 live cattle three to four years old, as well as about 100,000 tons of fresh (chilled) beef.

Mode of Preparation:—All bone and gristle is removed; 2lb. of raw beef is required to yield 1lb. of tinned meat. It is first partially cooked in baths, then in suitable pieces transferred to tins of 2, 7, and 14lb. weight. These are next wheeled to another set of baths, in which they remain two to seven hours, and are gradually cooked without any supposed loss of natural juice or aroma. Air escapes through a puncture in the lid, which is at once soldered up on removal from the bath. The cans are afterwards scrubbed and cleansed from grease in a machine and finally labelled by girls.

In comparing the value of cooked beef with the prices of fresh beef sold by butchers, it should be remembered that in a sirloin of beef weighing 40lb. there are 5lb. of bone; in the wing rib about 25 per cent. of bone. A sample of tinned corned beef analysed by Mr. Wignor gave the following results:—Water, 64·9; albuminoids, 24·44; fat, 6·71; saline matters, 4·76. When it is considered that tinned meat has no bone, that it contains less water and more fat and albuminoids than fresh meat, it is clearly a cheaper article of nourishment than ordinary butchers' meat.

Wholesale Firms.—Morris & Jones, 13, 15, and 17 Sir Thomas Street, Liverpool. (Also proprietors of the "Shorthorn" brand.)

Beers.—F. *Bière*; Ger. *Bier*; It. *Cerevesa*; Port. *Cerveja*; Sp. *Cerveza*; W. *Bir, Diod, Cwrw.* (See also *Ale, Porter, Non-alcoholic Beers*; and *Bottled Beers.*)

The varieties of beer are very numerous. The alcoholic classes are professedly brewed from barley and hops

maize, rice, and "invert sugar," or glucose being now freely used. In fact, modern beers are best described as fermented saccharine infusions, to which any wholesome bitter principle has been added. This bitter principle is professedly obtained from hops, but it is often from quassia, and sometimes from calumba chirata, gentian, wormwood, &c. Nearly 60 million bushels of malt and corn, and 100,000 tons of sugar are used yearly in the United Kingdom for beer, while the licence and other duties on beer amount to over £10,000,000 a year. Some beers are made from roots, and others parts of various plants, as ginger, spruce-sap, beet, molasses, &c. There are, however, only three principal alcoholic types of fabrication—the English, Bavarian, and Belgian. The beers of England, as of France, and for the most part of Germany, become sour by the contact of air; but this defect is absent from Bavarian beers. (Lager, Pilsener, Piwarrie, Mum, Quass, Spruce, and Ginger beers, as also ale, porter, stout, &c., are separately described in their alphabetical order.)

Gratzer beer is brewed from wheat malt in Austria.

Schenk is a Bavarian draught beer usually drunk in winter.

Bock Beer and *Salvator* are both dark, heavy kinds of stout, very popular in Bavaria.

Kaiserlautern is the name of a famous beverage in Rhenish Bavaria.

There are over forty kinds of beer made in Belgium, mostly rather tart; the white, sparkling beers of Louvain, in South Brabant, are perhaps the most esteemed, the winter brew being termed *Faro*, the summer *Lambic*. They are both made with unmalted wheat and barley malt. They contain about five per cent. of alcohol and only three per cent. of malt extract. The hardness arises from the large quantity of lactic acid which they contain. The Faro is prepared from the strong Lambic and a small beer called *Mars*.

Uitzet is made in Flanders, *Arge* in Antwerp, and *Port Saisons* in the Walloons. *Hougaerde* and *Diest* come next in repute. The brown beers of *Malines* and the *Saison* of Liege are also considered fair. *Leipzig Goose* and *Berlin White Beer* are both very refreshing drinks in summer, but, like all German beers, they are far less potent than English.

English ale and porter ordinarily contain 5 to 10 per cent. of alcohol (Burton 6 per cent., Scotch ale 9 to 10 per cent.), but Lager Beers only about 4 per cent. However, on the Continent, want of strength is usually made up in quantity. The annual consumption in the United Kingdom, per head of the population, is 30 gallons of beer, 1 of spirits, and nearly half a gallon of wine. In Germany, beer, 52½; in France, beer 5, wine 29½. The public analysts of England say that no "noxious substances" have been found in beer for over 20 years, but as beer may be prepared with any substitute for malt, and any substitute for hops, it would be difficult to say what is adulteration and what is not.

Excess of salt is often met with, though analysts differ among themselves as to the quantity admissible. The Board of Inland Revenue does not appear to interfere with substitutes which are harmless, such as quassia, glucose, saccharine, and there is no restriction as to the quantity of salt that may be added; but the use of *cocculus indicus*, which is a poisonous intoxicant, should certainly be prevented. There is no doubt that one-third of the beer manufactured in this country is made from the substitutes mentioned, and it is a pity that a man who desires a glass of malt liquor should be served with these vamped-up chemical concoctions. With spirits it is much the same.

Bees-wax.—Ger. *Wachs*; F. *Cire d'abeilles*; It. and Sp. *Cera*; Rus. *Work*.

The purified comb of the honey bee, prepared by melting the comb in boiling water after the honey has been removed; the melted wax is then strained, and cast into cakes, which have a pale yellow colour and a pleasant odour.

White bees-wax is formed by exposing the yellow wax in thin slices to light, air, and moisture, and then re-melting and forming it into cakes.

It used to be thought the bees obtained their wax from a few specific plants, but it has since been found to be nothing more than the voluntary excretion of the insect, like perspiration from the human body, and that bees can make it when fed on honey and sugar alone.

The wax of one species of bee common in Patagonia, Terra del Fuego, and other parts of southern South America, and the adjacent islands, is of a dark blue colour, and is said to be highly poisonous—more so than arsenic.

A large quantity is prepared in England, and also imported from abroad. The British is the best, and generally of a pale yellowish-brown colour, and of a pleasant odour; the foreign being mostly of a pale dirty colour, and often containing dead bees, dirt, &c. That from Gambia is perhaps the worst.

The best, of course, is *pure* bees-wax, as made by the bees and then highly refined. A second quality consists of 4 parts bees-wax and 1 each of white wax and resin. A third quality is made of 9 parts each of bees-wax and white wax, 2 parts of stearine, and 4 of resin.

It is, moreover, often adulterated with ceresin or paraffin, especially *Mogador* and *Japan Wax*, and if with less than about six per cent. it cannot be detected with certainty by any of the ordinary methods.

An enormous quantity comes from North America and Chili, but sometimes weighted with large stones of 7lb. to 14lb., and it is generally adulterated with either paraffin, collophony, resin, stearic acid, carnauba wax, or spermaceti; American frequently contains as much as 80 per cent. of paraffin wax. Black earthy matter also is occasionally moulded into cakes and cleverly coated with yellow wax, whilst other samples contain chrome yellow, yellow ochre, hæmatite, mineral wax, and only a little bees-wax. Paraffin, however, is the chief adulterant, and the white flat saucer wax is almost invariably adulterated with it. The fact is partly accounted for by the practice of bee-keepers putting into their hives comb foundations for the bees to build upon, these being ordinarily made of paraffin wax. When the bees-wax from such hives is melted down it may thus contain 10 per cent. of paraffin.

There has been much argument as to whether bees-wax is really a food or drug, so as to be covered by the Food and Drug Act. Decisions seem to point to the fact that when taken inwardly it is not really used as a medicine, but as a vehicle only, and not as possessing of itself any healing or medicinal properties. Judges also have remarked that no one who wanted to use bees-wax for medicinal purposes would think of purchasing it at a grocer's shop. It is, however, safest to sell such wax merely as white or yellow wax, and not as "bees-wax," unless sure that it is pure.

Special Firms.—Kimpton Brothers, 36 and 37 Mincing Lane, London, E.C.; John Parkes & Co., Priory Works, Warwick; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Beet.—F. *Bêtterave;* Ger. *Runkelrübe;* Port. *Betteraba;* Sp. *Remolacha;* W. *Betysen.* (See also *Mangold Wurzel*, etc.)

A sweet succulent plant of the genus *Beta vulgari*, of the order *Chenopodiaceæ*, and native of the sea-shore.

Four species are cultivated:—The common red beet; the mangel, or mangold wurzel (a large coarse kind, for

cattle only); the chard; and the slender-rooted sea-beet, cultivated for its leaves only.

There are many varieties of each species, some with carrot-like roots and others turnip-shaped. The small red *Beta rubra* are considered very wholesome for table use, contain about 80 per cent. of water and 10 per cent. sugar, and are often sliced in salads or boiled as a vegetable, but are considered best when baked.

The sugar-beet, *Beta ciela*, is a large white and very sweet variety, often called "*Silesian beet*." Its leaves are also used like spinach, and are frequently employed to adulterate tobacco, indeed, every part of the vegetable is utilised in one way or another. The pulp, after the juice has been expressed for sugar, is largely fed to cattle and found to be very nourishing. The leaves and stalks, when fresh, increase a cow's milk and enrich it; when dry, they afford excellent winter food. In fact, it has recently been discovered that beets, independent of the juice expressed for sugar-making, supply more abundant nourishment than any other forage ordinarily cultivated on the same kind of land. Sugar is a most important element of animal, as well as human food, and the starch of the beet is changed to sugar in the digestive process.

In France in 1881 it required 17 tons of beet-root to produce a ton of sugar, but in 1890 only 8½ tons.

Germany now cultivates about a million acres, which yield about 13 tons to the acre. About 13 million tons of the roots are submitted to manufacture, and yield some 1¾ million tons of sugar, or 12 per cent.

France grows only about half the quantity, and the roots practically yield only about 10½ per cent. of sugar.

Now that Spain has lost her interests in Cuba, she also is growing beet-roots extensively for sugar.

The *chard* is a small beet, chiefly cultivated in France and Germany for its leaves, which are used for human food in the agricultural districts.

Beets keep best in dry sand and are always seasonable.

Beet Sugar. — As early as 1747, Marggraf, a Prussian chemist, discovered that sugar could be extracted from the white Silesian beet-root, but a factory was not established till 1776. In 1799 one was started in Austria by F. K. Archard, a pupil of Marggraf, but the 2 or 3 per cent. of sugar that could be extracted by the methods then in use did not pay. The more extensive cultivation of the plant was, however, greatly encouraged by Napoleon I., during the war with England (1806), when cane sugar could not be got into France, and the percentage obtainable was doubled. In Great Britain it was not till after the Crimean war, when West Indian Muscovado sold at 65s. per cwt. in the Glasgow markets, that the saccharine potentialities of beet sugar attracted refiners in this country. In 1860 the total production on the Continent was only 400,000 tons, of which France contributed 146,000 tons; Germany, 125,000; Austria, 55,000; Holland and Belgium, 74,000. In 1884 the imports of beet exceeded those of cane, till now about three-fourths of the sugar consumed in England is beet-root sugar, and as it is all made abroad we pay Germany, France, Austria, Belgium, and Holland about fifteen millions a year for it.

In 1894-95 Germany produced 1,192,011 tons; Austria, 1,044,500 tons; and France, 745,100; and Belgium, about 265,000 tons. It is chiefly made from the *white* beet-root (*Beta ciela*), which is first washed and rasped, or grated by hand or machinery.

The wet pulp is then folded up in a number of coarse flannel cloths in the form of a square cake, and put upon an iron plate; another plate is then put on the top, then another cake of pulp, and so on until there are fifty, sixty, or seventy cakes piled one above the other. The whole mass is then subjected to a gradual pressure in a powerful hydraulic machine till finally a very great pressure is brought to bear on it, and 80 to 85 per cent. of juice is extracted. By the diffusion process, which is based on the

physical phenomena of endosmose and exosmose, 94 to 95 per cent. may be obtained. The roots, previously cut into small bits, are immersed in water, and the interchange between the water and the sweet juice of the beet begins at once, through the intermediary porous partition represented by the cells of the beet substance, which separates the water from the juice contained in the cells. This method has a great advantage over that of pressure, which detaches part of the fibrous texture of the beet and renders the juice more or less impure. Moreover, the pulp from diffusion contains more organic matter than that obtained from pressure, and is much more valuable as food for cattle on account of its greater nutritiveness.

The juice is somewhat dark coloured, and is not fit to eat till clarified, or as it is technically termed *defecated*, by elaborate processes of boiling in lime, skimming, filtering, etc. It is afterwards refined similar to cane sugar, and made equal in appearance to the finest kinds of "moist" or "lump" cane sugar. The use of animal charcoal in the manufacture of raw beet-root sugar is now becoming quite exceptional, and even in the refining process its use is falling off; but it is usually heavily blued to improve the colour. Some of the foreign made beet sugars imported into this country have been found to contain large percentages of *carbonate of lime*, hard flinty white crystals, wilfully left in, or added to the sugar to cheapen it. Of course it is quite legitimate to use lime in refining sugar, but to sell it to grocers, etc., thus loaded with this carbonated and insoluble substance, is grossly fraudulent.

The largest beets are not the best, for they often contain much poorer juice than smaller ones, and it is the juice which contains the sugar. Some roots contain 20 per cent. of sugar, others scarcely six.

The average total percentage of saccharine in German beet is now 15 to 16, while in France it is just over 14, or, say, 7lbs. of sugar from 100lbs. of beet. Of course the whole of it is not extracted. A few trials have been made in England and Ireland to grow sugar beets, but nothing seems to have become of them so far. Many think the palmy days of beet are over, and that cane sugar will soon regain its position.

The chemical composition of beet sugar is often argued to be identical with cane, but whether it is so in use is very doubtful. For confectioners, bakers, jam and British wine manufacturers, etc., beet sugar is certainly not desirable. It is not capable of high crystallisation; it assumes a redness under heat and imparts a dull dark colour to pastry and other light fancy goods, and it is of inferior sweetness, besides having the unpleasant flavour and taste known as "hogo."

Beetle Powders, etc.—(See also *Insect Powders*.)—For destroying black-beetles, cockroaches, etc.

(1) Mix well together a teacupful of fresh flour, a teaspoonful of white castor sugar, and enough red lead to make the whole of a light pink colour. Lay the powder every night in their runs on sheets of paper, say a tablespoonful on each sheet, and remove during the daytime to a safe place out of the reach of children.

(2) Mix plaster of Paris and oatmeal together, dry, and place where the beetles congregate. They eat the mixture greedily, and it is certain death to them.

(3) Lay wafers made up of red lead, flour, and sugar, equal parts.

(4) Mix equal parts of Persian Insect Powder and powdered Levantic wormseed. Scatter about the places which the cockroaches frequent.

(5) Mix arsenic solution with honey, boiled potatoes, bread, or treacle.

(6) Spread fresh cucumber peel every night on the floor where the beetles are wont to congregate; they are very fond of the juice, which, however, is a deadly poison to them.

(7) Put unslaked lime in their holes, or on the floor; or (8) use powdered hellebore in like manner.

(9) Wheat flour, 2 parts; powdered borax, 1; unslaked lime, 1; and

powdered sugar, 4; mix thoroughly and keep dry. Place on papers about infested localities.

(10) Mix a little treacle with beer in a deep dish; place a few sticks at the side so that the beetles may walk up and fall in.

(11) 10 parts powdered borax and 5 parts of precipitated carbonate of baryta.

(12) Take of cocoa in powder, 4 parts; starch, 8 parts; borax, 36 parts. Mix thoroughly. To be scattered on the floor in places where the beetles congregate.

Beetles caught alive in traps, etc., are easily killed by throwing them into hot water, but the habit of throwing water into ash-pits under the fire greatly encourages them.

Bell Pepper. — See *Capsicums.*

Benafouli Rice. — A very fine variety grown in Bengal, and which is said to be more easily digested than ordinary qualities, and emits a very agreeable aroma in cooking.

Bencoolen Tea.—See *Malay Tea.*

Bendi-Kai. — See *Gumbo* and *Okra.*

Benedictine. — See also *Liqueurs.* A liqueur or cordial closely resembling *Chartreuse*, but dating from the 14th century. Its predominating flavour is that of angelica. It was originally prepared by the Benedictine Monks at the Abbey of Fecamp, in Normandy, hence its name; and it is said that the principal inventor was the Abbe Antoine, also that he was made a cardinal for his pains, although the story is not perfectly authentic.

What is certain, however, is that Francis I. held the elixir in high respect, and protested that it acted as an antidote to all his ailments, which was perhaps only his way of saying that it warmed up the cockles of his heart when he was in low spirits. Before the Revolution of 1789 it was one of the most fashionable liqueurs of the day, but at that time it encountered a powerful rival in the *Liqueur d'Hondaye*, of which mention is made in the chronicles of the period. But this did not live long, and Benedictine once more became the vogue. The Revolution drove out the monks, and destroyed their abbey, and with them the secret of the composition of their liqueur was lost for many years.

Its ingredients baffled analyses, and the only hypothesis tenable concerning this cordial was that angelica and some mysterious plants growing on the "falaises" or cliffs of the Norman coast entered into its composition. In 1863, however, M. Legrand, an intelligent and enterprising inhabitant of Fecamp, whose name now appears on every label, managed to get hold of the archives of the ancient monastery, and after studying them found out the precious secret. At least so he said, and there is no reason to doubt his word. He began to distil the nectar, and with so much success that two years later a company was started under his direction for the manufacture of it on a large scale. The old abbey was rebuilt, and the distillery adjoining it was organised in the most scientific manner.

The bottles or flagons like those used for other monastic liquors are made of black glass and of carboy shape, but with a longer tapering neck, and encased in fine wicker work, are still labelled with the sign of the Greek cross, and the letters "D.O.M." (*Dei omnipotenti* (or *optimo*) *maximo*—To God Almighty very great and powerful). The Jesuits mark their product also with a cross, consecrated with the four letters, A.M.D.G. (*ad majorem Dei gloriam*—For God's greatest glory). The venerable abbey (which had been restored in the style of the Renaissance mixed with Gothic and the Roman), also the factory, were all accidentally burnt down in January, 1892, but the celebrated liqueur is now produced at a large new factory, and the annual output is about a million bottles. About 30 per cent. of the concoction is consumed in Finland by some 100,000 people, who make it their national cordial for all times, suitable or unsuit-

able, and despite its high price often drink it out of tumblers.

Benedictine is retailed in England at about 7/6 a flagon.

Bengal Chutney or **Chitni.**—See also *Chutneys.* This is a kind of Indian Chutney in paste or pulp form. It is usually prepared very hot by the addition of chillies, etc., and is then called *Bengal Hot Chutney. Bengal Club Chutney* is of only medium hotness and fairly sweet.

The following is considered a good average recipe for this favourite condiment:—Chillies, 1½lbs.; unripe mangoes or apples, 1lb.; red tamarinds, 2lbs.; sugar candy, 1lb.; fresh ginger root, 1½lbs.; garlic, ¾lb. to 1½lbs.; sultana raisins, 1½lbs.; fine salt, 1lb.; and about 3½ quarts strong vinegar.

Soak the chillies for about an hour, then grind all with a stone and muller to a paste or pulp.

Benicarlos Wine. — A dark red variety of considerable strength produced from the vineland surrounding Benicarlo, in Valencia, Eastern Spain. This wine is extensively used for blending with other red kinds, especially Bordeaux.

Many of the cheap Ports are also manufactured from Benicarlos Wine, and some 250,000 casks are said to be exported annually for this purpose, a great portion of it going to Cette, in France.

Benne or **Bene Oil.**—See *Gingelly* or *Sesame Oil.*

Bennin Pepper. — See *Cubeb Pepper.*

Ben-oil or **Behen Oil.** — Lat. *Oleum Balatinum.*

This has no connection with the above *oil of Benne* or gingeli seed, but is the expressed oil of the *ben-nut*, the winged seed of the horseradish tree, *Moringa pterygosperma*, which resembles the willow. This bland and inodorous and colourless oil is remarkable for its agreeable flavour and for remaining many years without going rancid. At a temperature near freezing point it deposits its solid fats, and the remaining liquid portion is used in extracting the perfumes of flowers, and by watchmakers for the lubrication of delicate machinery; also as hair-oil, owing to its power of retaining odours it is highly valued by perfumers. It is also used in preparing Macassar oil, and sometimes as salad oil.

The best ben-oil, however, is said to be derived from the seeds of *Moringa aptera* of Abyssinia and Arabia.

Benzine or **Benzol.**—F. *Benzine;* G. *Benzil;* It. and Sp. *Benzina.*

These are colourless volatile liquids, usually distilled from light coal-tar naphtha, or gas tar oil, and consisting chiefly of *benzol* C6 H6, specific gravity about 0·85. Also procured from benzoic acid and slaked lime. *Benzine Collas* is a high-priced and much-advertised French make, the firm pretending that Collas was the inventor of benzine, but there seems no real difference between this and other cheaper makes. These preparations are extensively employed for the removal of spots of grease, paint, etc., from woven fabrics, and are quick solvents for gutta-percha, indiarubber, paints, varnishes, etc.; in fact, benzine dissolves all the oils, resins, gum-resins, varnishes, and fats, and is therefore very useful. It is much the same thing as *petroleum spirit.* To distinguish coal-tar benzol from petroleum benzol, add a crystal of iodine to a few drops of the benzol; it will give the former a violet-red, and the latter a raspberry red colour.

Benzoline. — Port. and Sp. *Benzolina*—(Also known as *Petroleum Spirit, Petroleum Ether,* etc.).

A colourless, very volatile, and highly inflammable liquid obtained from American rock oil or petroleum, and often consisting of a mixture of the lower members of the paraffin or marsh-gas series of hydrocarbons. Boiling point 122° to 140°F. Specific gravity 0·670 to 0·700. Largely used as a lubricant for motor machines.

If used for burning purposes, care should be taken to use a sponge lamp so as to ensure the vapour (which is extremely inflammable) being well diluted with fresh air when burnt. A licence under the Petroleum Acts is required for its storage.

Bergamot Essence. — This pear-like perfume may be made either from the essential oil of Bergamot and methylated spirit, say eight parts of 95 per cent. alcohol to one part of oil of Bergamot, mixed and coloured with tincture of grass; or, better still, by grating the gold-coloured rinds of Bergamot oranges, then squeezing out the juice of the rind and filtering it.

Bergamot Oil.—An essential oil obtained from the flowers or rinds of the Bergamot orange (*Citrus bargamium*), so called from the city of Bergamo, Lombardy, in the North of Italy, where the tree first grew. But the oil is now only produced in Reggio, at the extreme South of Italy, and is mostly exported through Messina.

Both the flowers and the rinds of the Bergamot orange yield this fragrant oil, which seems to derive its delicious pear-like fragrance from the acetic ester of linalool. An inferior sort is also made from the roots of the tree. There is also an excellent round pear named "Bergamot," from its melting juicy pulp and pleasant flavour, but this is no relation to the above citron.

Bergamot oil is extracted in the same way as lemon oil, and probably no other essential oil is so heavily adulterated.

When pure it is a limpid, yellowish fluid, having a smell resembling that of the orange. Its specific gravity varies from 0·888 to 0·885.

It becomes concrete when cooled a little below 32°F.

Turpentine, oil of lemons, oil of sweet oranges, resin, pitch, and even stearine are all commonly added to cheapen oil of Bergamot.

The crucial test is the proportion of a substance called *Acetato di liniale*, for it is this ingredient which gives its odour to the essence.

Berlin Blue (also called *Steel Blue*) is obtained in same way as *Prussian Blue*, but is usually a little lighter in colour.

Bermuda Arrowroot.—The Bermuda Islands were acquired by Great Britain in 1609.

They are a group of islands in the North Atlantic, twenty miles square, with a population of 17,500. Their chief products are early vegetables, bulbs, and arrowroot. On account of the smallness of this colony, foreigners are not allowed to be naturalised or possess land. The imports are £304,893, the exports £101,163, and the revenue £34,356.

Hitherto no authentic account has been given of the interesting arrowroot industry carried on in Bermuda. One reason for the superior character of Bermuda arrowroot is the scrupulous care taken in every stage of the manufacture. The mode of culture is very similar to that of the common potato. The roots, after being collected, are washed, and their outer cuticle completely removed. This process requires care, for the cuticle contains a resinous matter which imparts colour and a disagreeable flavour to the starch, and cannot be removed by subsequent treatment. The pared roots are then well washed, and crushed to a pulp between powerful rollers. The pulp is thrown into perforated cylinders, where it is agitated by revolving wooden paddles, while a stream of pure water carries off the fecula from the coarser fibres of the pulp, and discharges it through the perforated bottom of the cylinder. Thence it is conveyed in pipes, and passed through fine linen strainers into reservoirs, in which it is allowed to settle, and the supernatant water drawn off. After repeated washings, it is again allowed to settle for some time, when the surface is skimmed with palette knives of German silver. The rollers and cylinders are made of brass and copper. The drying is conducted with equal care and cleanliness. The substance, spread in flat copper pans placed on rollers, is covered with gauze

and run under glass-covered sheds when there is danger from rain or dew. When dry it is packed with German silver shovels in new barrels lined with paper, which is stuck in with arrowroot paste. The barrels are exported on the deck of vessels under cover, since, if placed in the hold, the arrowroot might be tainted by the effluvia of other freight.

Betel. —F. *Chique de bétel.* (See also *Areca Nuts.*)

This is the name of a popular masticatory extensively compounded and chewed by the natives throughout the East. In India it is called *Adiki* or *Addaca;* the Malays call it *Pinang;* the Hindoos, *Suapril;* the Javanese, *Jambi;* and in some places it is called *Sirith.* It is prepared by folding the kernels of the areca or betel-nut palm (*Areca catechu*), a little powdered slacked lime (*Chunam*), and sometimes a little terra japonica, in the leaf of the betel pepper (*Chavica betle*), a species of climbing vine largely cultivated in the East Indies, Ceylon, Burma, Siam, etc. The Philippine islanders wrap the nut in buyo leaves smeared with lime. The betel roll, or "Buyo," thus prepared is hot and acrid, with considerable aromatic and astringent properties, and often very intoxicating; it tinges the saliva red, and soon blackens the teeth and gums. The juice is sometimes, but not always, swallowed.

The Southern Asiatics of both sexes and of all ages carry "*betel*" in small pouches, and are perpetually chewing it to sweeten the breath, dispel nausea, strengthen the stomach, and to give a bright red colour to the lips.

On ceremonial visits these betel pellets are often the only refreshment offered to Europeans by the natives, and are usually presented wrapped in gold or silver leaf, and in elegant "betel boxes."

Its use has been traced to very remote antiquity, and to refuse to accept "betel" would often give irreconcilable offence. Its use may be compared to tobacco chewing, smoking, or snuff-taking in this country, or to coca-leaf chewing in Peru.

Betel nuts were only introduced into this country as a medicine in 1867.

Betel leaves have been found to be highly beneficial in catarrhal affections and throat inflammation.

Beverages, various. — F. *Boissons;* G. *Getränke;* Sp. and Port. *Bebidas.*

These may be found under their respective names. See *Aerated Beverages, Aerated Waters, Mineral Waters, Temperance Drinks, Non-alcoholic Beers* and *Wines, Cider Perry, Ales, Arrack, Pulque Spirits, Cherry Brandy, Kali, Maté, Tea, Coffee, Cocoa.*

Bhang. — Also known as *Churrus, Momeca, Gunjah, Hasheesh,* etc. These are all Indian narcotics. *Churrus* or *Charas* is the name used in districts north of the Punjab for a resinous exudation obtained from the tops of the hemp plant, *Cannabis sativa,* worth 5/- to 10/- per lb., and gathered by men clad in leather dresses, who run through the hemp fields brushing violently through the plants, when the soft resin adheres to the leather and is afterwards kneaded into balls. Sometimes the leather dress is dispensed with, and the resin is collected on the skin of the naked coolies.

It has been used, as has opium, since Indian history began, and is more intoxicating than either Ganja or Bhang.

Gunjah, Guaza, or *Ganja* is the name for the extract secreted on the female flowering or fruiting shoots. It is used for smoking, and is popular as a sort of tobacco, for it is supposed to have medicinal properties as an anti-spasmodic and anodyne, but its continued use often leads to idiocy.

Bhang is a name given to the larger dried leaves and slender stalks, which are also known as "Tubjee," and "Siddha," or "Sidee."

They are also roughly broken and mixed with some of the fruits. Bhang is of a dark green colour and chiefly used for smoking; an intoxicating drink is also made by infusing it in water, and adding a few seeds of stramonium. Bhang, when mixed with

flour, sugar, etc., is also made in India into a kind of sweetmeat called "*Majoon*" or "*Majun*."

Momeca is a superior kind of resin, collected by hand in Nepaul, and worth nearly twice as much as ordinary *Churrus*.

Biborate of Soda. — A technical name for *Borax*, which see.

Bi-carbonate of Soda, or **Baking Soda.** — This is made by first melting the crude carbonate of soda (*Sodium carbonate*) in hot water, and then cooling it in shallow pans, when it forms into large soda crystals. This crystallised soda is next exposed in an atmosphere of carbonic acid, so that while absorbing the acid, the crystals lose their water, and eventually fall into a white powder, which contains twice as much carbon as of crude soda (*Sodium carbonate*) and hence its name of *bi*-carbonate.

By mixing almost any acid or acid salt with bi-carbonate of soda, this carbon will be turned into carbonic acid and pass off as gas; thus, 20 parts of bi-carbonate of soda will neutralise 16½ parts of citric acid or 17½ parts of tartaric acid.

Bi-carbonate of soda is largely used in preparing baking powders, self-raising flours, etc., and a special kind is employed in the production of aerated beverages. It is also useful in medicine. In cases of slight burns, dusted over the surface, it often affords great relief; so, too, it does if inserted into the decayed cavity of an aching tooth. In weak solution it, as well as the stronger and cheaper carbonate of soda, or "washing soda," when applied to the skin, gives great relief from the itching of prickly heat or of hives. Its internal use as an antacid to correct sour stomach, or to relieve heartburn or indigestion, is well known.

Dose for an adult say ½ oz. mixed in a tumbler of water. Sold wholesale in 1 cwt. kegs.

Brunner Mond & Co., Northwich, Cheshire, are now the largest manufacturers.

Gardner's patent "Rapid Sifter and Mixer, freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Bilberries.—See *Whortleberries*.

BILBERRY.

Biltong or **Biltongue.** — A name for sun-dried meat in Cape Colony. The dried flesh of the ox or wild buck. Very popular with the Boers in Africa, and often called *South African Venison*.

Bicycle Oil. — There are various sorts sold under this name, mostly mixtures of sperm with paraffin or neats-foot oil. Some are adapted both for lubricating the machine and for burning in the lamp, while others are intended for only one of these uses.

Bicycle Tyre Cement. — In 6d. and 1/- pots. A good one is made by melting two parts of asphalt and one part of gutta-percha together in an iron pot. It must be applied hot.

Another.—Dissolve 20 ozs. caoutchouc and 10 ozs. gutta-percha in 10 ozs. of carbon bisulphide, then add 5 ozs. fish glue. After applying, bind the tyre with cord until cement is well set.

Apply to E. Mitchell & Sons, 5 Burnett Place, Bradford, Yorks.

Biffins or **Beaufins.** — See *Norfolk Biffins, Dried Apples*, etc.

Bigarde or **Bigarade Oranges.**— See *Bitter Oranges.*

Bigarreau.—See *Cherries.*

Birch Tar Oil. — A pyroligneous oil (*Oleum rusci*) distilled from the bark of the white birch, *Betula alba*, a forest tree met with everywhere in the North of Europe. It is this oil which gives Russia leather its characteristic odour, and also which helps it to resist mould and damp, birch bark being commonly used in Russia for tanning. Russian, German, and Dutch varieties are, however, by no means uniform. An extract of birch is not infrequently used to perfume inferior leather goods to make purchasers believe they are getting good Russia leather.

In fact, this peculiar smell is now no more Russian than Eastern, and is often due to the process or curing by the smoke of leaves instead of tanning.

Bird Foods. — See *Bird Seed*, also *Poultry Foods.*

Bird Lime. — F. *Glu;* G. *Vogelleim;* It. *Pania;* Port. *Visco;* Rus. *Ptilochei;* Sp. *Liga;* W. *Glyd.*

A viscous substance of greenish colour, made from the inner or middle bark of the mistletoe and the holly. It has a bitter taste and an odour like linseed oil. The bark is first boiled several hours in water, then the thin water is poured away, and the substance retained, and after being allowed to stand exposed to the air about fourteen days is beaten into a pulp until it becomes thick and sticky. Afterwards small twigs are smeared with it and placed where birds are likely to light on them. Bird lime is also made of mistletoe berries, young elder shoots, the bark of the *Wayfaring* tree, etc., by a similar process. Another kind is made by boiling half a pint of linseed oil with a little resin on a slow fire, stirring occasionally, till it thickens or turns stringy. When the desired consistency is attained it is poured into cold water. Should it stick to the hands it may be removed by a little turpentine.

Bird-nest Soup.—See *Edible Bird-Nests.*

Bird Peppers (variously known as Bird's-eye chillies, Red bird-pepper, &c.).—The ordinary term in the West Indies for the Cayenne pod, small red chillies, or *Capsicum minimum.* This plant grows nearly five feet high, with lucid green leaves, and produces the ordinary cayenne of commerce. The pods are green at first, but turn to a bright orange or scarlet colour when ripe, and are then gathered and dried in the sun.

Some "Red bird-pepper" has an agreeably aromatic flavour and very pungent taste; it is sometimes pounded with salt, preserved in bottles, labelled and sold as Cayenne pepper.

But there is another sweet, and sometimes tasteless, variety of *C. annuum*, which often passes as "Pod Pepper," although more correctly described as "*Bird Pepper.*" Both of the above kinds are received in quantity from Japan, Jamacia, Zanzibar, Spain and Portugal.

This sweet variety possesses very little pungency, contains a large amount of fatty matter, is dark in colour, and is said to heighten the colour of the feathers. Although supplied by two or three firms, its exact source is very difficult to trace. It was originally supposed to come only from the northern part of South America. Professor Archer thinks it is produced by *C. tetragonum*, which has a much blunter fruit than the *C. annuum*, and is obtusely four-angled. It is very largely used in Hungary and in Spain.

Bird Seed. — F. *Graine d'oiseaux;* G. *Vogelsamen;* Port. *Græs de passaro;* Sp. *Granos de pajarro.*

Bird seeds have a large sale in some of the manufacturing districts. The following mixings are all popular:—

(1) All canary seed.

(2) 20 parts canary and 4 of rape.

(3) 20 parts canary and 4 of hemp.

(4) 15 parts canary, 2½ of hemp, 4 red millet, 1½ summer rape, and 1 of inga seed.

(5) 16 parts canary, 2 hemp, 3 rape, 2 millet, and 1 part of English linseed.

William Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

"*Colour Food*" *for Birds.*—The chief ingredient in this is *Capsicum annuum*, the non-pungent variety of capsicum which has an intensely red, oily pericarp. It can only be obtained from a few of the leading wholesale seed merchants. Some of these powders contain, as well, a little turmeric, bread-crumbs, and some of them sugar. It has been found that almost any colour which will dissolve in oil, if given in that solution, will permeate the feathers, and even the bones and the eggs of birds constantly fed with food containing it.

Bird's Eye Chillies. — See *Chillies.*

Bird's Eye Tobacco. — (See also *Tobacco.*) — Generally manufactured from the unstripped leaves of Kentucky, Missouri, and Ohio growth, and forming when ready for use a loose fibrous mass with thin slices of stalk interspersed, the latter somewhat resembling *birds' eyes.*

Birthday Cakes. — See *Bride Cakes.*

Biscuit Powder or **Meal.**—(See also *Prepared Foods*, or *Infants' Food.*)—A preparation for the use of invalids, children, &c., and composed of selected kinds of crushed or ground biscuits that have been broken or damaged in manufacture.

Cheap biscuit powders are also used largely by manufacturers of sausages, saveloys, &c. Some consist chiefly of sweepings of the factories, ovens, or from returned empties.

Biscuits.—Amer. *Crackers*; F. *Biscuits de luxe*; G. *Zweibäcken*; Port. *Bolaxas*, *Bis-costas*; Sp. *Biscochos*, *Galletas*; W. *Cras-deisen.*

Biscuits are the oldest form of bread. At what period of man's history the lightening of dough by fermentation was first adopted no one, of course, knows. It is, however, certain that cakes made of nothing but meal and water and then baked are very much older. Fragments of unfermented cakes were discovered in the Swiss lake dwellings which belong to the Neolithic age, an age dating back far beyond the received age of the world. This is the earliest instance of biscuits as yet discovered, for biscuits are merely unfermented bread. Although this rude form of bread was early discarded for the fermented variety, yet in this, as in many other matters, it was found convenient to return to a discarded and apparently valueless process. Thin, unfermented cakes were found to possess merits for special purposes. They would keep good for a great length of time, and they were convenient to carry, and thus afforded wholesome and nutritious food in a portable and convenient form. The simplicity with which they could be made and baked was also a point in their favour. The word "biscuit" embodies the process by which biscuits were made from time immemorial to within the last century, if not, indeed, later. Bis, twice or double, and cuit (coctus), cooked, shows that they were twice baked; and although the double process has now been discarded, yet the name is retained.

The pastry-cooks of Rheims were the first to produce *Fancy* biscuits, and, indeed, it was only about 1840 that England began to manufacture these dainties in earnest. The tremendous factory which now dominates the whole town of Reading, and on which the 70,000 inhabitants of that town largely depend, owes its origin to the late Mr. George Palmer, who some 60 years ago joined Mr. Thomas Huntley in his business in that town, which was originally established in 1826.

One of the first and most popular biscuits was the "Picnic," but since that time every year has witnessed the introduction of numerous other fancy

descriptions, until the "Biscuits de Rheims" have been quite superseded, and the French have had to begin afresh by copying the *genre anglais*.

Biscuits are usually made from very stiff dough, which has been subjected to no fermentative action, and are baked for only a very short period of time; we might almost call it a mere drying. The dough is simply collected in receivers and put through a series of rollers to be reduced to the proper thickness, after which it is cut by machines into the desired sizes and forms, and then baked in tins or passed through ovens on an endless band or chain until sufficiently *dried*. The fancy kinds require special manipulation in order to add to the decorations, and this is done with great rapidity by girls, each with a bag of icing, which is pointed like a pencil, to draw with, upon the cut paste, before being passed through the oven. Sometimes this ornamenting is done after the biscuit or cake has been partly baked.

The quality of the flour is not so important as for bread, and the kind most used is that called "soft." But some kinds of biscuits are made from strong flour, especially the low-priced sorts, where bulkiness is the chief consideration. For the large farthing and halfpenny biscuits, sold in low neighbourhoods, the soft or biscuit flour would be useless, also in biscuits of the "cracker" series, which require flour well proportioned with gluten to make them spring, and to produce the flaky appearance.

Local customs, tastes, and styles vary in different districts regarding biscuits.

The softest kinds of flour are, however, generally used for what are called the finest class of *Tea*, *Wine*, *Marie*, *Paris*, and *Nile* biscuits. These *soft* flours also colour much better than the *strong* ones.

The best biscuits for keeping are those made from flour and water, like the hard, old-fashioned *Sea Biscuits*.

To preserve their crispness and flavour, all biscuits should be stored in a cool, dry place, and not exposed to heat, air, sunlight, or moisture.

Biscuits made from unsound, musty flour, or if not sufficiently dried, or if kept in a damp place, soon develop fungi and weevils. Damp atmosphere also soon penetrates ordinary biscuit tins, and produces a putrefactive change in the form of mould of either the *A. glaucus* or *M. mucedo* species, or perhaps both.

The presence of lard or butter accelerates the growth of *Mucor mucedo*, especially during warm weather. The surface becomes covered with small white filaments, called *hyphæ*, which terminate in rounded heads or *sporangia*.

Sugar, however, exercises a retarding influence, and the more sugar in them the better they will keep; hence, the reason why most of the biscuits exported to India and other warm countries are the "mixed," or sweet kinds.

The harder a biscuit is dried in the oven the longer it will keep.

All plain biscuits *without* sugar require a *much warmer oven* to bake them.

Rich biscuits always contain more or less warm moisture in themselves, hence they are liable to go rancid if kept long; but they keep better and longer in small tins than in large tins or boxes, where the heat naturally becomes much greater. Of course, to add much sugar to some kinds, such as plain lunch, milk, toast, &c., or to make other rich sorts without butter or lard, would make them keep better, but would render them different biscuits altogether.

All *soft* biscuits containing much sugar, however, soon soften if exposed long in a moist atmosphere, and even plain sugarless kinds are soon affected by air or moisture.

Water biscuits, for instance, if exposed to the air for any time, become soft owing to the moisture of the atmosphere.

An excessive use of soda is commonly betrayed by a mousey smell and fla-

vour, very unpleasant to most people. This is very noticeable in Crackers, and other plain kinds.

A ginger nut is, indeed, an excellent barometer, for when exposed to the air it becomes softer in proportion as the moisture of the atmosphere increases.

Biscuits when hard and crisp practically contain no moisture at all, but when exposed to the air they are soon assimilated to it. If moister, they turn soft and moist; if drier, they turn harder and drier. (The same is the case with bread.)

Excessive paleness or whiteness in biscuits is not considered a good feature, but usually suggestive of age or imperfect baking, both of which are fatal to the rich bloom of freshness and good flavour.

Some kinds are considered deleterious from admixtures of alumina compounds derived from alum.

There are upwards of 600 sorts of biscuits made, and a general descriptive catalogue would doubtless be very useful to retailers.

The piles of biscuit tins in shops and warehouses are often a severe strain to the eyes of assistants hurriedly seeking particular kinds. Manufacturers, in fixing upon the colours or the arrangement of names on labels, might consider this, so as to simplify the task by some methodical arrangement of the tints. Why not offer a prize to assistants for the best plan?

With the view of assisting retailers who may be asked for a kind of biscuit they are not acquainted with, the following descriptive list is submitted.

The sizes and prices named are those of the principal manufacturers:—

Explanations.—The figures in brackets indicate the leading manufacturers, thus: (1) means Carr & Co., (2) Crawford & Sons; (3) Gray, Dunn, & Co.; (4) Huntley & Palmer; (5) Jacobs & Co.; (6) Macfarlane, Lang, & Co.; (7) Mackenzie & Co.; (8) McVitie & Price; (9) Peek, Frean & Co.; (10) Powell, Son, & Co.; (11) Walker & Co. Rd. means that the title is registered by the makers; *Plain* means unsweetened; C or R denotes circular or round biscuits; D, Diameter; W, width; L, length; T, thickness; and the approximate dimensions are given in inches or fractions of an inch. Prices vary with different makers, and the figures named are merely approximate.

Names of Biscuits, Makers, Description as to Shape, Size, Weight in Square Tin or Half Tin, Price per Cwt., &c.

A B C or ALPHABET (4, 7, 9, &c.).—Small round, sweetish, a letter on each, 320 to lb., 39/-.

ABERNETHY (7).—Several sizes, ¼d., ½d., and 1d., also smaller; thin, round, sweetish. See separate mention in body of book.

AFRICAN (4).—L 2½, W ¾, furrowed surface, rich, sweetish, 90/-.

AFTERNOON TEA (4).—12 sorts mixed, sweet.

ALBERT (4, 7).—C. D 2½, T ¼; sweetish, 50 to lb., 7½lbs. in tin, Osborne or Arrowroot type, and named after the late Prince Albert.

ALBERTA (4).—Oblong, L 2½, W 1¾, T ¼, 58/-.
ALGERIA (1, 4, 5, 7).—Oval, L 2¼, W 1⅛, T ⅜, pointed ends, sweet, brown icing underneath, 60 to lb.
ALMOND DROPS.—See special reference to these in body of book.
ALMOND RINGS (1, 2, 4, 5, 6, 7, 8, 9, 11).—C, D 2½, T ¼, hole in centre, sweet, 66 to lb., 8lbs. in tin.
ALPHABET.—Small ovals, L 1, W ¾, with a letter stamped on each, 300 to lb., 42/-.
AMERICAN CRACKERS (6, 9).—Plain light squares, 29 to lb., 35/-.
ANGEL CAKES (8 Rd.).—Spongy and sweet, bun shape, D 2, T 1¼, rose flavour, piece of fruit on top.
APRICOT WAFERS (5).—4¼lbs. per tin, retail price 1/4 per lb.
ARABIAN (7).—A nicely flavoured biscuit.
ARCADE (9).—Round, rich, cocoanut flavour, 54 to lb., 59/-.
ARROWROOT (2, 4).—Circular or oval, various sizes, sweetish, pricked.
,, Rich, C, D 2¾, T ¼, not pricked, sweetish, 72 to lb.
,, (4,) Thick
,, (4, 5) Thin, C, pale colour, figured border, scalloped edge, 76 to lb., 6¾lbs. per tin, retail price 7½d. per lb.
ATLANTIC (5, 9).—Round, plain, 200 to lb., 40/-.
BALMORAL (2, 3, 4, 6, 9).—Three shapes (crown, rose, shell).
BALTIC (1).—Plain, very thin, C. D 2¼, T ⅛, 120 to lb., white and closely pricked.
BANQUET (9).—A sponge finger biscuit with chocolate icing, 80 to lb., 98/- per cwt.
BANQUET WAFER.
BATAVIA or BATAVIA NUTS (7, 9).—Round, sweet, 38 to lb., 32/-.
BATH or BRIGHTON (4).—Round, sweetish, 7¼lbs. per tin.
BATH OLIVER (FORTT'S).—A high-class, slightly sweetened, but troublesome to make. (See separate article.)
BEATRICE (4).—Sweetish.
BENGAL NUTS (9).—Ginger bread, 68 to lb., 26/-.
BIARRITZ (4).—A long dessert biscuit, sweetish.
BISCOTTES DE PARIS or BISCUITS DE PARIS.—The French name for *Rusks*.
BISCUIT POWDER (7).—See prepared foods.
BON BONS (2, 3, 5, 6, 7, 8, 9, 11).—Gingerbread, 32 to lb., 37/-.
BON BOUCHE (4).—Dry, sweet, citron flavoured.
BOUDOIR (4, 9).—A sort of sponge finger, sugared on on side, flavoured with vanilla, sweet, and very delicate.
BRAEMAR (3).—A superior unsweetened biscuit.
BRAZIL (4).—Sweetish.
BREAKFAST (1, 4, 7, 9).—Plain white rusks, oblong, L 3 W 2½, T ½, 50 to 60 to lb., 3lbs. in a tin, 8½d. per lb. retail.
BRIGHTON (2, 3, 4, 6, 7, 9).—Round, D 1¾, similar to Dover but smaller.
BRILLIANT (3, 9).—Various shapes, mixed, sweetish, 144 to lb., 31/-.

BRITANNIA (4).—Large plain, with a figure of Britannia marked on each.
BROWN COLLEGE (4, 6, 7, 9).—C, D 3¼, T ¼, brown meal, 26 to lb., 6½lbs. in tin, very like Granola.
BRUNSWICK (6, 9, 11).—Round, meal, sweetish, 32 to lb., 61/-.
BUFFET (4).—Plain.
BUTTER (1, 2, 4, etc.)—C, D 3, T ¼, closely pricked, not sweet, but rich.
BUTTER CREAMS (5).—10¾lbs. per tin, 6d. per lb.
BUTTERSCOTCH (5).—C, D 3, T ¼, very sweet, brown, smooth surface, 50 to lb.
BUTTON NUTS (4).—Very small, sweetish.
BUXTON (4).—Sweetish.
CABIN (1, 2, 4, etc.).—C, D 3, similar to Captain and Lunch, round, plain, 20/-.
CAFE NOIR (1, 2, 4, 5, etc.).—First made by Carr & Co., oblong, L 3, W 2, T ⅙, 30 to lb., brown icing underneath, 6¾lbs. per tin, 5½d. per lb.
CALAIS (8).—Round, with triangular projections, D 2½, T ¼, 64 to lb., sweetish.
CAMP (4).—Plain.
CANADA (9).—Round, plain, light, 44 to lb., 39/-., 4¾lbs. in tin.
CAPE (4).—Sweetish.
CAPTAIN (6).—Round, various sizes, plain, like lunch, 38/-.
,, Thin (2, 3, 5, etc.).—C, D 2, T ¼, light colour, plain cracker, 100 or 120 to lb.
,, Thin Oval (1, 5).—6¼lbs. per tin, 5d. per lb.
CARICATURE (4).—Sweetish, each biscuit bears a humerous portrait stamped on it.
CARLSBAD SUGAR WAFERS.—See separate reference in body of book.
CARNIVAL (6, 11).—Oblong, L 3, W 2, T ¼, 70 to lb., 6lb. tins, scalloped edges.
CASINO (4).—Sweet, 5lbs. in tin, 84/- cwt., 1/- per lb.
CELERY (9).—A crisp savoury biscuit with celery flavour for use with cheese or butter, square tins, 47/- cwt.
CHALET (4, 7).—Oblong, L 3, W 1, T ¼, sweetish, rough surface, like Colonial, 70 to lb.
CHARCOAL (Bragg's).—Special sizes, 9d. per lb.
CHARLOTTE (9).—Oblong, striped with two different coloured doughs, sweet, 96 to lb., 58/-. Introduced 1894.
CHARM (1, 2, 4, etc.).—Various shapes, slightly sweet, 264 to lb., 36/-.
CHATEAU (3, 9).—Light brown finger, vanilla flavour, for dessert, 100 to lb.
CHEAPSIDE (4).—Sweetish.
CHEESE (1, 2, 4, 7, etc.).—Oval, L 2¾, W 2, T ¼, scalloped edges, plain, 60 to lb., 5lbs. in tin, 38/-.
CHERRY CREAMS (9).—A round sandwich with scalloped edge, and containing a layer of cherry-flavoured cream.
CHERRY WAFERS (9).—Cerise colour, finger shape, similar to Venice wafers in size and style, but sandwiched with cherry-flavoured cream.
CHICAGO (7).—Oval, L 3, W 2½, T ⅛, cracker like, white colour, 58 to lb., 5¾lbs. per tin, 5½d. per lb.
CHIEFTAIN (7, 9).—Oval, slightly sweet, 72 to lb., 40/.
CHOCOLATE (6).—9lbs. per tin, 9d. per lb.

CHOCOLATE WAFERS (4).—Sweet.
CLIFFORD.—C, D 2¾, T ⅛, top marked with pea-like globules, 44 to lb., sweetish.
CLUB.—Sweetish.
COBURG CAKES (9).—Round, sweet, with peel, 34 to lb., 63/-. Similar to Louise but with small pieces of peel in centre.
COCOA-NUT DROPS (4).—Sweet.
COCOA-NUT RINGS (4).—Sweetish.
COCOA-NUT WAFERS (4).—Sweet.
COFFEE (3, 4, 9).—Oblong, L 2¾, W 2, T ¼, sweetish, 50 or 60 to lb., 78/- cwt.
COLOMBO (9).—Crisply baked *cocoa-nut*.
COLONIAL (1, 2, 3, 5, etc.).—Oblong, sweetish, L 2½, W 1⅛, T ¼, 96 to lb., rough furrowed surface, 7lbs. per tin, 5½d. per lb.
COMBINATION (3, 4, 5, etc.).—30 odd fancy shapes mixed, sweet.
COMEDY (9).—About 30 humorous figures, 248 to lb., 36/-.
CONSTITUTIONAL (1).—A selection of small mixed.
CONVERSATION (4).—Sweetish.
CORNISH CREAM (4, 9).—Plain, white, crisp, milk biscuit for use with "Cornish Cream" or cheese after dinner.
CORONET (4, 9).—Round, D 2, impressed with a crown, scalloped edge, sweetish, 56 to lb., 35/-.
COWSLIP.—A nicely baked, fully coloured and crisp variety, retailed at 6d. per lb.
CRACKNELS (3, 4, 11).—See separate article in body of book.
CREAM CRACKERS (2, 3, 4, 5, etc.).—Plain, white, sq., L 3¼, W 3, T ⅛, 50 to lb., 3½lbs. in a tin, 6d. per lb.
CREAM SANDWICH (9).—Two layers of biscuit sandwiched together with a sweet creamy material, 48/-.
CRINKLE (4).—Finger shape, white and curly, L 3, W ¾, 56/-.
CROQUETTE (4).—Sweetish.
CROWN (4, 9).—Large round, D 5, Royal Arms in centre, scalloped edge, slightly sweet.
CUDDY (4, 9).—Plain, hard, C, D 4, T ⅜, 14 to lb., 7½lb. tins, 20/-, 3d. per lb.
CYCLIST (8).—Oval, L 3, W 2, T ¼, 48 to lb., 6lbs. in tin, slightly sweet.
CYCLIST LUNCH (1).—A sandwich biscuit specially intended for cycling and picnics, 42/-.
CYPRUS CAKES (4).—Lemon, chocolate, coffee, rose.
DAINTY CAKES (1, 2, 9).—Raspberry and black currant, round open jam tartlets, or cross between a biscuit and a tartlet.
DAISY or DAISY CAKES (1, 2, 9).—Currant, Madeira, o Sultana, like Fairy Cakes, but smaller.
DEMI-LUNE (1, 2, 4, etc.)—Vanilla flavoured, sweetish, 47 to lb., 47/-.
DERBY (1, 2, 3, etc.).—Ginger, Small, and Vanilla, C, D 3, T ¼, sweetish, 50 to lb.
DESSERT (2, 3, 4, etc.).—Mixed sorts, 16 kinds, sweet, richly ornamented, 115/-.
DIADEM (4).—Medium, 28 kinds, sweet.
DIGESTIVE (1, 2, 3, 4, etc.).—C, D 3, T ⅜, hard, plain, brown meal like Brown College.

DINNER (4, 9).—Plain, small, and crisp, for use with soup, etc., instead of bread.
DOMINOES (4).—Sweet.
DOROTHY CAKES (2, 3).—7lbs. in a tin.
DOT (9).—Very small, sweetish, 940 to lb., 46/-.
DOUBLET (1 Rd.).—Light, plain, circular cut, but folded in oblongs before baking, 53/-.
DOVER.—Round, D 2½, slightly sweet, 56/-.
DRESDEN TEA CAKES (1, 8).—Rich cocoa-nut flavour.
DUCHESS (3, 8, 9).—Rich light finger, 120 to lb., 112/-.
DUDLEY (9).—Square, sweet ginger flavour, 56 to lb., 40/-.
DUTCH RUSKS (4).—Sweetish.
EASTBOURNE (4).—Sweetish.
EMPIRE (4).—Sweetish.
ELFIN CAKES (11, Rd.).—Round or shell shape.
EUROPEAN MIXED (9).—Sweet assortment, 58 to lb., 55/-.
EXCURSION (4).—C, D 2¾, T ¼, plain, with caraways, 32/-.
FAIRY CAKES (2, 3, 5, etc.).—Currant, Madeira, Sultana, and iced, D 2, T 1, soft, sweet, 7½lbs. in a tin, 7½d. per lb.
FAMILY (4).—Sweetish.
FANCY RUSKS (4).—Sweetish.
FANCY SHORTBREAD (4).—Sweetish.
FANCY SWEET (4).—24 kinds, sweet.
FAROLA (6).
FAVORITE (4).—Lemon or vanilla, sweetish.
FAY (4).—Sweetish.
FILBERT (4).—Imitation filbert, baked in moulds, split lengthwise, sweetish, 80/-.
FINGER GINGERBREAD (2, 3, 4, 7, etc.).—L 3, W 1½, T ⅜, 40 or 60 to lb., 10lbs. in tin, Ginger-nut type, sweetish.
FINGER RUSKS (4).—Sweetish.
FIVE O'CLOCK TEA (5).—6½lbs. per tin, 7½d. per lb.
FLORAL (9).—Various shapes, sweet, 65 to lb., 69/-.
FOLKESTONE (4).—Sweetish.
FRAME FOOD (7).
FRUIT (4).—Sweetish.
FRUIT DROPS (1, 4, 7).—C, D 1¾, showing 3 or 4 currants on top, sweetish.
GARIBALDI (1, 2, 3, etc.).—Sq., L 2¾, W 2½, T ¼, wit currants inside, sweetish.
GEM.—Small, sweetish, 500 to lb., 30/-.
GENOA (4).—Sweet.

GERMAN RUSKS (4).—4¾lbs. in tin (see separate mention).
GINGERBREAD CAKES (1, 2, 3, etc.).—Round or sq., sweet, ¼d., ½d., and 1d., 35/- to 85/-.
GINGERBREAD LEAF (4).—Sweetish.
GINGERBREAD FINGERS (4).—10½lbs. per tin, 10d. per lb.
GINGER NUTS (1, 2, 3, 4, 6, 7, etc.)—Light brown colour, hard, tough, sweetish, rich, 42 to lb., C, D 2¼, T ⅜, 9lbs. per tin, 6d. per lb.
GINGER SNAPS (1, 3, 7, etc.).—See separate reference to Ginger Snaps and Ginger Nuts in body of book.
GINGER WAFERS (4).—Sweetish.
GIPSY CAKES (8, 9).—Not unlike Fairy and Daisy Cakes, but cheaper (retail at 6d).
GLACE (4, 6, 7).—Oblong, L 2½, W 1, T ⅜, sweet, smooth icing underneath, 70 to lb., 1/- per lb.
GOLDEN NUTS (8).—Round, sweet, 32 to lb., 52/-.
GOLF (7).—Contain meat extract, and are intended for sportsmen, tourists, and others.
GOSSAMER (9).—Square, plain, light, 50 to lb., 39/-.
GRAMPIAN (4).—Sweetish.
GRANOLA (6, Rd.).—C, D 3¼, T ¼, brown meal and sweetish, very like Brown College, 8¼lbs. per tin, 8d. per lb.
GRANVILLE (9).—Sq., sweetish, 66 to lb., 54/-.
GROSVENOR (7).—Apricot, marmalade, raspberry, and strawberry flavours.
HEALTH (9).—Sq., plain, flaky, 56 to lb., 67/-.
HEART CAKES (9).—Sweet, soft, 36 to lb., 62/-.
HONEY DROPS (4).—Sweet and soft, about twice the thickness of a florin, golden brown colour.
HOTEL (9).—Round, plain, crackers, 200 to lb., 40/-.
HOLIDAY (4).—Sweet.
HOUSEHOLD (4).—Metropolitan mixed, 19 kinds, sweet.
ICE CREAM (1, 2, 3, 4, etc.).—Various colours and flavours, rich, 254 to lb., 192/-.
ICE WAFERS (4).
ITALIAN FINGERS (9).—Sweet, 66 to lb., 54/-.
ITALIAN WAFERS (2).—Thin, oblong, L 3¼, W 1¾, T ⅛ inch, gimped edges, sweetish, 96 to lb.
IVANHOE (11).—9lbs. in a tin.
JAM FINGER (4, 9).—Raspberry and currant, sweetish, a finger sandwich, 52 to lb., 56/-.
JAMAICA (4, 7, 9).—Sharp-cornered oblongs, L 2, W ⅝, T ½, sweetish, 84 to lb., 78/-.
JUVENILE (4, 9).—Very small, sweetish, 1,180 to lb., 28/-.
JEWEL CAKES (9).—Sweet, soft, and round. In centre a sugared fruit confection, made in four different flavours.
KETTLEDRUM STICKS (TORRENCE).
KIMBERLEY (GINGER CREAM) (5).
KINDERGARTEN (4).—Sweetish.
KINGSTON.—Crisp and with a ginger flavour.
LEAFLET (9).—Various leaves, sweetish, 220 to lb., 66/-.

in a tin, retail at 6d.
LEMON DESSERT (4).—Sweet.
LEMON FINGER (1, 2, 3, etc.).—Sweet, lemon flavour, 128 to lb., 28/-.
LEMON NUTS (1, 7, 9).—Gingerbread, lemon flavour, 48 to lb., 48/-.
LEMON RINGS (1, 2, 4, etc.).—Similar to Almond Rings, but lemon flavoured (see separate mention).
LEMON WAFERS (4).
LEOPOLD (4).—Three-cornered fancy shape, sweetish, 150 to lb., 70/-.
LEVANT (9).—Oblong sultana sandwich, 48 to lb., 46/-.
LITTLEFOLKS (4).—Sweetish, 7½lbs. per tin, 6d. per lb.
LORNE (4, 9).—Oblong, L 3, W 1, rich, light, 95 to lb., 136/-.
LOUVRE (9).—Round, soft, light and sweet, 64 to lb., 68/-.
LUNCH (4).—Several sorts:—City, Edinburgh, Eiffel, Fancy, Fine, Halfpenny, etc. (see "*Lunch Biscuits*").
MACAROONS (AMERICAN) (5).—8lbs. in tin, 11½d. per lb.
MACAROONS (ITALIAN) (4).—Several kinds and shapes, very rich and sweet, pieces of almonds, sugar, or comfits on top.
MADEIRA (4, 5, 8).—Thin fingers, L 4, W ¾, T ⅜, Savoy type, sweet, white sponge, 120 to lb., 8¼lbs. in tin, 1/1½d. per lb.
MADELEINE CAKES (4).—Sweet.
MADRAS (8, 9).—Large cocoanut drops, 25 to lb., 44/-.
MADRID (1).—Cocoanut flavour.
MAITRE D'HOTEL (4).—Sweet.
MAIZENA, Rich (4).—C, D 1¾, T ¼, "Maizena" in circle, sweetish.
,, Wafer (2, 3, 4, etc.).—See separate mention in body of book.
MALTA (4, 7, 9).—Oval, sweetish, 92 to lb., 62/-.
MALVERN (9).—Round, thin, sweet, 72 to lb.
MARGATE (6).—7lbs. in tin, 6d. per lb.
MARGUERITE (9).—Finger, sweetish, 96 to lb., 62/-.
MARIONETTE (4).—Sweetish.
MARIE (1, 2, 3, 4, 5, etc.).—Sweetish, C, D 2½, T ⅛, 7 to lb., 8lb. tins, 60/-, *Osborne*, *Oswego* type, 7½d. per lb.
MARLBOROUGH (9, 11).—Round, soft, sweet, almond flavour, 108 to lb., 56/-., 4lb. tins.
MASCOTTES (9).—Round, rich, soft, 58 to lb., 90/-.
MATLOCK (5, 7).—C, D 2¼, T ¼, sweetish, light colour, flat smooth surface, 68 to lb.
MAUD (9).—Round, sweetish, 80 to lb., 38/-.
MAYFAIR (11).—Sweet Sandwich, in various flavours.
MEAL (4).—Plain.
MEAL WAFERS (4).—10½lb. tins, 7½d. per lb., sweetish.

MEAT.—See separate reference in body of book.
MEDALLION (4).—Small oval, L 1¼, W 1, *Pearl*, *Gem*, and *Alphabet* type.
MEDIUM (1, 3, 4, etc.).—About 15 fancy rare shapes, mixed sweet, 64 to lb., 60/-.
MELLIN FOOD.
MELROSE (6, 3).—C, D 2¼, T ¼, 50 to lb., 7½lbs. in tin, *Osborne* type.
,, Gingerbread (3).
METROPOLITAN (1, 2, 6, etc.).—Mixed sweet, 112 to lb.,28/-.
MIDLOTHIAN OAT-CAKES (7).—Made from finest Midlothian oatmeal.
MILK (4, 5, 6).—C, D 2½, T ⅛, plain, closely pricked, figured border, 70 to lb., 6lbs. in tin, 36/-, 5d. per lb.
MINARET (6, 7, 9).—Iced finger, sweet, 96 to lb., 33/-.
MIXED (4, 6, 7,).—Sweet (several sorts:—Champion, Harvest, Household, London, National, People's, Rich, Venetian), 8¼lbs. per tin, 10d. per lb.
MIXED CREAMS (4).—Sweet.
MIXED PEOPLES (7).—8lbs. per tin, 5d. per lb.
MODEL (7, 9).—Small figures and stands, several shapes, 300 to lb., 36/-.
NAPLES (4).—Sweet.
NATIONAL (9).—Round, sweetish, 52 to lb., 50/-.
NELSON (2, 3, 9).—2 inch square, a sort of fruit sandwich, like Garibaldi, 54 to lb.
NIC NAC, FANCY (4, 6, 7, 9).—Small, various shapes, sweetish, 200 to lb., 32/-.
NICE (4).—Pronounce *nee-see*, sweetish, 6¾lbs. per tin, 6½d. per lb.
NILE (3, 5, 9).—Round, sweetish, 86 to lb., 42/-, 7¾lbs. i a tin, 5½d. per lb.
NONPAREIL (4).—Plain.
NONSUCH (4).—C, D 1¾, T ¼, rich, 73/-.
NURSERY (4).—Sweetish, round, and light, 17 to lb., 54/-, 3½lbs. per tin, 7½d. per lb.
OATCAKES or SCOTCH FARLS.—Various shapes and sizes, plain and sweet.
OATEN (4).—Sweetish, oblong, L 2½, W 2, T ¼, coarse oatmeal, 20 to lb., 11 lbs. in tin, 64/-, 8½d. per lb.
OATEN WAFERS (5).—10lbs. in tin, 7½d. per lb.
OATMEAL WAFERS (7, 8).—Sq., D 3, T ⅛, sweetish, 3 to lb., 6lbs. in tin.
OBAN (4).—Ginger snaps, sweetish.
OBELISK (9).—Iced finger, 104 to lb., 35/-.
OBERTINE.—See separate notice in body of book.
OCEAN (4).—Plain.
OPERA WAFERS (4).—Sweet, 8½lbs. in tin, 1/7 per lb.
ORANGE DESSERT (4).—Sweet.
ORANGE DROPS (4, 5, etc.).—Round, sweet, 76 to lb., 55/-.
ORIENTAL (4, 7).—Almond flavoured and sweet, shape of a hen's egg split lengthwise.

OTTOMAN (3, 5, 6, etc.).—Round, sweet, cocoanut, 50 to lb., 45/-.
OVAL THIN CAPTAIN (4).—L 2, W 1¾, thinner than Captain, 40/-.
PAGODA (9).—Ornamented finger, sweet, 130 to lb., 36/-.
PALACE (4).—Sweetish.
PARK (9).—Round and rich, 60 to lb., 74/-.
PARMENA (6).—A savory cheese biscuit.
PASSOVER CAKE (for Jews).—Apply to Solomon & Son, 26 Widegate Street, or Levy Bros., 31 Widegate Street, London.
PATENT SANDWICH.—Chocolate, cocoanut, and raspberry.
PEARL (4, 5, etc.).—Small oval, sweetish, 194 to lb., 39/-.
PEOPLE'S MIXED or COMBINATION.—20 varieties, mixed, sweet, 96 to lb., 39/-.
PETIT BEURRE (4).—2½ sq., T ¼, sweetish, 48 to lb., Osborne or Marie quality, 8¾lbs. in a tin, 6½d. per lb.
PETTICOAT TAILS (or Petites Gatelles) (8).—A Scotch dainty in round tins.
PIC-NIC (1, 2, 4, etc.).—Oval, L 1¾, W 1½, sweetish, 100 to lb., 42/-.
PICKWICK (4).—Sweetish.
PITCAITHLY BANNOCKS (8).—Flat round cakes of oat, rye, or barley meal.
PLAIN WAFERS (4).—Plain.
PRAIRIE (4).—Plain.
PRESBURG (4, 6, 7, 9).—Oblong rusks, L 2, W 1, sweetish, rough surface, encrusted with chopped almonds.
PRINCE (4, 9).—Round, sweetish, 28 to lb., 34/-.
PRINCE OF WALES (1, 5, 9).—Round, plain, 32 to lb. 30/-.
PRINCESS (1, 9).—Finger, very light, 116 to lb., 224/-.
PRINCESS SHORTBREAD.—Small cakes of cocoanut and chopped almonds.
PROMENADE (9).—Iced, Lemon, Chocolate, Vanilla, and Coffee flavours.
QUEEN (4).—Sweetish.
QUEEN DROPS (1, 2, 3, etc.).—Fruit Drops with currants, 58 to lb., 90/-.
RASPBERRY WAFERS (4).—Sweet.
RATAFIA.—See separate references in body of book.
READING CRACKERS (4).—Plain.
REGALIA (5).—2½lbs. per tin, 8d. per lb.
REGINA (9).—Various shapes, sweet, 116 to lb., 60/-.
RHINE.—Two oblongs stuck together, L 3, W 1⅛, T ½, scalloped edges.
RICH TRAVELLER (4, 7).—Oval, L 2¼, W 1½; see separate reference in body of book.
RIFLE NUTS (5, 9, 11).—Gingerbread, 126 to lb., 37/-.
RIVIERA (4).—Sweet.
ROCKET (9, 11).—Round iced, various colours and flavours, decorated on one side, 70 to lb., 46/-.

ROLL (4).—Finger shape, L 4, W ¾, T ½, 56/-.
ROSE (5, 7, 9).—Rose shape, sweet, 92 to lb., 71/-, 2½lbs. per tin, 8d. per lb.
ROSETTE (6, 9).—Cocoanut drops, 80 to lb., 91/-.
ROYAL (1, 3, 4, 7).—C, D 2⅜, T⅛, figured border, Queen's head in centre, 72 to lb., sweetish.
,, Dessert.—Rich, mixed, 16 sorts, 102 to lb., 115/-.
RUGBY CAKES (9).—Sweet, soft, 18 to lb., 58/-.
RURAL (Zoological) (4).—About two dozen animals, sweetish and brittle, 140 to lb., 7lbs. in tin.
RUSKS, Fancy (4).—Oblong slices, toasted, for children, luncheon and dinner use, L 3, W 1½, T ¾, 45 to lb., 3lbs. in tin, 86/-, 1/- per lb.
,, German (2, 4).—See separate reference in body of book under *Rusks*, 2½lbs. per tin.
SALOON (4, 5, 9).—Large round, thin, and plain, 26 to lb., 36/-, 5½lbs. per tin, 4d. per lb.
SALT (4).—Plain.
SANDRINGHAM (6, 9, 11).—Oval, rich, light, 136 to lb., 68/-.
SANDWICH (1) Introduced 1894.—Several layers of doug of different colours and flavours, Rasp, Cocoa-nut, Chocolate, Coffee, etc.
SAVOY (1, 4, 5, 8).—Two sponge cakes stuck together, white and very sweet.
,, Fingers.—L 3, T 1, 40 to 50 to lb.
SCHOOL (1, 4, 9).—Round, sweetish, 100 to lb., 28/-.
SEA BISCUITS.—See separate mention in body of book.
SEASIDE (5, 9).—Round and sweetish, 56 to lb., 35/-.
SEED (4).—Plain.
SHORTBREAD.—See separate article.
SHREWSBURY (4).—Sq., L 1½, W 1⅛, T ¼, furrowed surface, rich and sweetish, 150 to lb., 86/-.
SMYRNA (4, 5, 6, etc.).—Sweetish Currant Drops, 92 to lb., 58/-.
SNOW FLAKE (3, 4, 9).—Finger shape, plain, 60 to lb., 39/-.
,, DROPS.—Very small, plain.
SOCIAL (4, 5, 9, 11).—C, D 2½, T ¼, 60 to lb., 7lbs. in tin, baked brown, sweetish.
,, Thin (1, 4, 7, 9).—C, D 2¼, T⅛, sweetish, 70 or 80 to lb.
SODA (1, 4, 7, 9).—Round, plain, 48 to lb., 58/-.
SOIREE (4, Rd.).—D 1¾, floral border, rich and sweetish.
SPICE NUTS (4, 5, 7, 9).—Sweetish, round, and spiced ginger nuts, 41 to lb., 60/-.
SPONGE (3, 4).—See separate mention in body of book.
SPONGE RUSKS (4).—Sweet.
SPRAY (4).—Plain.
STAFFA (6).—Small jam sandwich.
STAMINA MALT (7).—Contain extract of malt, very strengthening and sustaining.
STAR (4, 5, 9).—Round, sweetish, and iced, 108 to lb., 47/-.

SUGAR WAFERS (4).—Sweet, oblong sandwich shape, L 3½, W 1¾, T ⅛, various flavours (very popular in France).
SULTANA (4).—Sweetish.
SUPPER (2, 3, 4, etc.).—Plain, light cracker-like, C, D 3, T ⅓, 30 to lb., 4lbs. in tin.
SWEET (9).—Round, sweetish, 22 to lb., 35/-.
SWISS (4).—Sweet.
SYLVAN (9).—Leaf-shaped and sweetish, 136 to lb., 56/-.
TABLE (1, 4, 9).—Pencil-shaped, L 3, sweetish, 245 to lb., 40/-.
TANTALLON CAKES (6).
TEA (4, 6, 7).—Round, D 3, T ⅓, 30 to lb., sweetish, and soft, 6 or 7lbs. in tin, 6½d. per lb.
TEA RICH (4).—Sweetish.
TEA RUSKS (4).—Sweetish.
TEA THIN (4).—Sweetish.
THEOBROMINE (4).—Chocolate colour and flavour, in small tins.
TIFFIN (2, 7, 9, 11).—Finger shape, sweetish, 100 to lb., 42/-.
TOAST (4, 5, 9).—Square, plain and light, 36 to lb., 49/-, 5lbs. in a tin.
TOPS AND BOTTOMS (4, 9).—See separate reference in body of book.
TOURIST (2, 3, 4, etc.).—C, D 2¼, T ¼, pricked, sweetish, 40 to lb., 42/-.
TOWN (4, 9).—Large, round, sweetish, 11 to lb., 34/-.
TRAVELLER (4).—Plain, C, D 2, T ¼, 48 to lb., 28/-.
TRINIDAD.—A round cocoa-nut variety, lightly baked and of good flavour, retailed at 8d.
TUNBRIDGE or TUNBRIDGE WELLS (4, 6, 7, 9).—Caraway, Citron, Ginger, and Lemon flavours, C, and oval, rich, sweetish.
TYROL (4).—Sweet.
UNIVERSITY (4, 9).— Roll, sweetish, and light, 140 to lb., 72/-.
UNIVERSITY PLAIN (4).—Plain.
VANILLA MIXED (9).—Rich, mixed, 96 to lb., 71/-.
VANILLE (4).—C, D 2¼, T ¼, notched border, 75/-. VANILLA (4).—Sweet.
VARIETY (4).—28 kinds, sweet, 7¾lbs. per tin, 8d. per lb.
VENICE (4).—Sweet.
VENICE WAFERS (9).
VICTORIA (4 and 6).—Round, triangular, and heart shapes.
VICTORIA NUTS (1, 4, 9).—Sweetish, gingerbread, 32 to lb., 54/-.
VICTORIA WAFERS (5).
VILLAGE (4).—Sweetish.
WALDECK (7).—Sweetish, and prettily designed for five o'clock tea.
WALNUT (2, 4, 5, 7, 9).—Imitation walnuts, sweetish, 70 to lb., 50/-, 2½lbs. in tin, 10½d. per lb.

WATER (4, 5, 6).—C, D 3, T ⅛, 52 to lb., 6½lbs. in tin, plain, white colour.
" Small; see separate mention in body of book.
WATER CRACKERS (4).—Plain.
WAVELET (9).—Oblong iced, pine-apple flavour.
WATER FLAKED (5).—5½lbs. in tin, 4½d. per lb.
WHEATEN (1, 4, 7, 8, 9).—Oblong, sweetish; see separate reference in body of book.
WHEATMEAL (4).—C, D 2¾, T ¾, rough, coarse, brown, short but sweetish, 30 to lb., 10½lbs. in a tin, 56/-.
WHITBY.—Round and sweet, with currants, 30 to lb., 42/-.
WHITE NUTS (4).—Sweet.
WHOLEMEAL (9).—Thick and round, 42 to lb., 64/-.
WINDSOR (11, Rd.).—D 1¾, 6 or 8 currants on top.
WINDSOR WAFERS (5).—10lbs. per tin, 11d. per lb.
WINE (6, 7).—7¾lbs. per tin, and 6½d. per lb. YACHT (4).—Plain.
YORK CAKES (4).—Oblong, L 2½, W 1, sweet and spongy, with currants, 64 to lb.
ZEPHYR (1).—Square, very like American crackers.
ZELLER WAFERS (9).—Very thin, crisp, and of novel shape; 10 varieties: Anchovy, Celery, Cheese, and Oriental Cheese are all savoury, while Regina, Cigarette Ice, Cigarette Vanilla, Imperial, and Cone are sweet. The savoury four are intended for use with butter, and the sweet with cream, custard, ices, etc.

Bitter Almonds. — See *Almonds.*

Bitter Oranges. — Also calle
Bigardes, Seville Oranges, Sours, etc.

These oranges are all classed a
Bigaradia, but the origin of this term i
uncertain. They sometimes take th
name of *Seville,* the city around whic
large quantities of them have bee
grown, ever since the Moorish conqueror
first planted the orange tree i
Andalusia. These come packed i
boxes containing 300 oranges, each bo
measuring 28 by 14 by 10½ inches
The tree is a very handsome one, an
the hardiest of the orange genus. It
said to have been derived from a gra
of the citron and orange trees.
shoots freely in England, producing larg
leaves, and is noted for its beautifu
flowers, or "orange blossoms," which ar
of a delicate white colour, with
delicious odour, and when made int
wreaths are very popular decorations fo
brides, as emblems of purity. Th
costly *oil of neroli* is also made fro
these flowers.

Bitter oranges, or "*Sours,*" as the
are called by dealers, also come fro
Portugal, Malaga, Palermo, Syria, et
Perhaps the best come from Denia, o
the east coast of Spain, but those fro
the Canary Islands fetch the highes
prices. They have a roughish skin
rather thick, acrid, bitter pulp, an
are generally large in size. Th
tree is large, having a hard wood
and in many places develops a trunk
great dimensions; the leaves are of
brilliant, agreeable, green colour, ar
matic, lanceolated, and with a broadly
winged petiole.

These oranges are considered ver
valuable, and, having very bitter rind
are mostly used for making into marma
lade, orange wine and other bitte
tinctures, candied peel, and for flavou
ing *Curaçao.* The fresh peel is als
carefully dried in spring for the use
distillers, druggists, and perfumers.

Bitters. —F. *Amers.*
A conventional term for certain bitte

ıd often spirituous liquors in which ıtter herbs, roots, or barks have been eeped and soaked.

That of the hotels and public-houses usually a compound made by steeping ıtter substances, such as orange peel, ıssia, aloes, gentian, cardamom seeds, ıd other aromatics in weak spirits enerally gin) for some eight or ten days ıd then straining, a little sugar or rup being added subsequently.

Rue Gin is a preparation of this class. he well-known tonic or *bitter cup* is ade of quassia wood, and the roasted ips of this wood are often used as a bstitute for hops in embittering beer.

Prairie Bitters is an American bever- e common among the hunters and ountaineers of the West made with a nt of water and a quarter of a gill of ffalo-gall. The best known kinds of tters are *L'Amer Picon* (with 40 per nt. of alcohol), *Angostura Bitters*, *nnecamp Bitters*, *Bordeaux Bitters*, *randy Bitters*, *Calisayne Bitters*, *avre Bitters*, *Hop Bitters*, *Khoosh tters*, *Orange Bitters*, *Peruvian*, *crestat Bitters* (with 47 per cent. of ohol), *Stoughton Bitters*, *Wild erry Bitters*, and *Wine Bitters*, all of ich are put up in bottles of various es and prices.

Doctors say they are very bad for the mach, and soon affect the brain.

As most of the Bitters contain more less of spirit, a license is necessary.

Bonnekamp or *Maag-Bitter*, the eciality of an old Antwerp innkeeper, is ry popular in Holland and Belgium, ıere it is usually taken with Holland's ı. It was first manufactured in 1815 a Hollander of that name. There e now nearly as many makers of Bonnekamp" as of Worcestershire uce, but the original recipe is the operty of the Masquelier family, who rchased both the recipe and the inn out 1855.

Bitumen.—See *Pitch*.

"Bivouac" Tins of Meat.—See *nned Meats*.

Blackbeetle Powders.—See *Beetle wders*.

Blackberries.—See *Brambles*.

Black Bread.—See *Rye*.

Black Cloth Reviver.—See *Cloth Revivers*.

Black Currants.—F. *Cassis*. (Also known as *Quinsy Berries*.)

These are classified as *Ribes nigrum*. The trees are raised in the same way as the gooseberry, but the best fruit and fullest crops are from new wood of the previous year's growth. The best varieties are "The Black Naples," "Lee's Prolific" (very sweet and good cropper), "Carter's Champion," and "Baldwins." The *Black Naples* (or "Black Grape") is now almost universally cultivated. It bears short bunches, but the berries are very fine and large. Black currants are often bottled whole (see *Bottled Fruits*), and large quantities are made into jam. Wines, jellies, and lozenges are also prepared from the fruit juice.

The Russians preserve black currants in brandy, and the Irish in whisky, in same way as cherries are often preserved in England. The Russians also ferment the juice with honey, and so form a strong and palatable wine.

In some districts the young leaves of the bush are often used as a substitute for tea, and one or two of the buds or half a small leaf will import to black tea the flavour and fragrance of green tea.

There is no easier fruit to grow than black currants, which require no training nor staking whatever. Unlike gooseberries and other currant bushes, suckers are induced to grow up from the roots every year, as the finest fruit is grown on the young wood; the older and weaker wood is cut out as soon as the fruit is gathered, to allow the tree to confine its energy to new shoots, which should be left 5 or 6 inches apart.

It is one of the best paying fruits to grow, prices never being lower than £22 a ton.

Black Currant Jam.—(See also *Jams*.)—The fruit should be gathered while quite dry, and be carefully picked

over. In some factories the currants are strigged by machinery and not by the fingers. The currants are simply spread on a band, which is ever passing upward, and at the top is a revolving brush, which removes the strigs from the fruit, and the currants roll down ready for boiling. A good jam may be made as follows:—Put 14lbs. fresh fruit and three quarts of water into a copper pan (iron gives a metallic taste to the jam) and stir till it has boiled ten minutes. Then add 16lbs. white sugar, stir well, and boil about twenty minutes; then pour it into a pan-mug, or bowl, and pot while warm. Some people rub the fruit through a sieve, but that spoils the flavour entirely, so does the use of common sugar; besides, the currants themselves have a great tendency to congeal, and if good sugar be used they do not require so much boiling. It must be remembered that Black-currant jam is more liable to candy than any other jam.

Black Currant Jelly.—(See also *Table Jellies.*)—This is a compound of mucilage and acid. It should be prepared from perfectly ripe fruit, and may be made thus:—Boil 10lbs. large fresh fruit, quite ripe and sound, and 2 quarts of water, for 10 minutes, pour into a jelly bag, and let it strain 6 or 8 hours; then add 1lb. of white sugar to every pint of juice, and boil till nearly as stiff as treacle; remove scum, and pot. It loses its power of gelatinising by prolonged boiling.

Some jam manufacturers pass the fruit through fine wicker sieves, and then put the pulp into flannel straining bags, to extract the juice before adding the sugar and boiling. (The skins and seeds of the fruits are afterwards used in making second quality jam.)

Currant jellies are best fresh-made, and, being very liable to ferment, should not be kept long in stock. The fruit juice is usually stored by the manufacturers, and the jellies only made as required. To preserve them for a long time would require an amount of sugar that would render them far too sweet.

Adulterants: Glucose, apple jelly starch, acetic acid, and aniline dyes.

Black Currant Syrup. — The sweetened juice of the fruit put up in bottles for the use of chemists in dispensing and for confectioners.

A spirituous liqueur or cordial made from black currants, is very popular in France (see *Cassis*). Large quantities of the berries are grown around Dijon, Angers, etc., for this purpose, but strange to say, very rarely is jam or jelly made from them.

Black Currant Wine.—See *British Wines.*

Black Ink. — See *Writing Inks.*

Black Jack. — (See also *Burnt sugar colouring.*)—A shop name applied to a preparation of burnt or roasted sugar which is used to adulterate or darken coffee, and so give it a semblance of strength.

It is sometimes called *Coffee Finings.* One kind is used for colouring vinegar, another for rum, brandy, etc.

The name "*Black Jack*" is also given by miners to a sulphide of zinc, or blend of 67 of zinc and 33 of sulphur, and in some districts, Birmingham, for instance, a confection of senna passes under that name.

Black Jack Coffee.—In America is a low grade of coffee from Germany. It is a mixture of the dead and green berries of the poorest quality which have been picked out of ordinary coffee, and really unfit for consumption. To deceive the public into believing it to be pure, a coat of glaze is put over the berries which hides the deception and makes them appear bright and inviting.

Black Lead. — Du. *Potloot;* F. *Plombagine, Potelot;* G. *Pottlot, Reissblei;* It. *Miniera di Piombo,* Sp. *Plumbagine* or *Minerale de Chumbo, Piedra Mineral de Plomo,* Welsh *Plwn Du.*

The name "Black Lead" is one of convenience, and is universally understood, although it is not technically correct, because the mineral really contains no *lead* at all, and the term

herefore a misnomer. Its proper name ould be *Graphite* or Plumbago. Lead elts readily, but this article will stand ery great heat, and, in fact, so incom- ustible is it that in conjunction with lay it is the very substance chosen for aking crucibles or melting-pots.

It consists chiefly of a mixture of arbon, with alumina, silica, lime and xide or sulphate of iron, and is found n many parts of the world, but mostly n Bavaria, Spain, America, Siberia, and eylon, sometimes in beds, but often in etached pieces at random, and is arketed in blocks, lumps, chips, and ust, as low as 5/- per cwt., according o purity from other earths, and refined y sifting and washing with hydrochloric cid. It is then worked into a paste by rinding in a sort of mortar mill, or dged stones, with a mixture of paraffin il, water, naphthalene, and soap. When of proper consistency this is ressed by hydraulic or hand power into locks of any size desired.

The circular blocks are spun round in die, so as to leave a glossy surface on op. Lead has been found purest in orrowdale, Cumberland, where it used o fetch as much as 25/- to 30/- per lb.

Since the Cumberland and also the iberian deposits of graphite or plum- ago have been exhausted, the chief upply of this mineral has been derived rom Bohemia, in the south of which ountry, near Ochwartzbach and lurgan, deposits of pure graphite are ound in the gneiss, accompanied by rystalline limestone.

The mines and works at the former lace are owned by Count Schwartzen- urg, and those at the latter by the easants. These two centres yield the urest graphite now available, that of rumman being far inferior. The ineral, not being sufficiently pure o be sent away as natural gra- hite, is ground in mills constantly aversed by a stream of water that takes p the powder, which afterwards settles nto "mud," and when this mud layer as attained a sufficient thickness, it is subjected to a pressure of 88lbs. per square inch in a filter press. The re- sulting cake, containing more than 20 per cent. of water, is then dried in a stove heated to 90° or 100° (mean 203°F.) for 24 hours. Excellent gra- phite is now sold in Bohemia at about 15/- per cwt.

The best qualities are soft, marking the paper easily, and rubbing out quickly, also quite black (not slate- coloured) and without much lustre until well rubbed.

Low-priced black leads are usually made from Austrian or Hungarian lead, costing about £3 a ton, and with glucose and water can be produced, wrapped, labelled, and boxed at a total cost of about 6d. a gross for 1 oz. blocks.

"Black lead" is used for making pencils, and for polishing stoves and other metal work; also, like grease, for diminishing friction in machinery, belt- ing, and in fire-arms.

Special Firms.—Barringer & Co., Ltd. (manufacturers), Rock Valley Mills, Mansfield, Notts; "Enameline" Manu- facturing Co. (Enameline Paste), Drury Buildings, Water Street, Liverpool; W. G. Nixev. Soho Square, London, W.; Morris & Jones (all saleable kinds), 13, 15, 17 Sir Thomas Street, Liverpool; Punch Polish Co., Hick Street, Birming- ham (F. Cooke, proprietor).

Black Pepper. — F. *Poivre noir;* Ger. *Schwarzen pieffer;* It. *Pepe nero;* Jav. *Mariha;* Lat. *Piper nigrum;* Malay, *Lada;* Port. *Pimenta preta;* Sp. *Pimienta negra.* (See also *Pepper, White Pepper*, etc.)

The small dark unripe berries or fruit of *Piper nigrum* or Black Pepper vine, a native of the East Indies, and now cultivated in Sumatra, Java, and many other tropical countries.

The tree, generally propagated by cuttings or suckers, is a sort of shrubby climbing vine trained by poles or other trees some 10 or 12 feet high, but will grow 20 feet high if allowed.

It has a soft stem and broad tough leaves, which grow singly, and it fruits

when three or four years old, the long fruit-spike jutting out from the side of the twig exactly opposite the leaf, each spike containing 20 to 50 peppercorns.

The plant yields two crops a year, of 5 or 6lbs. each, for ten or fifteen years, but is in perfection at its seventh year; although after the third year of planting the summer crop is inferior to that of the winter, and, of course, seasons vary; while some regions never yield but very inferior growths indeed.

The spikes or twigs are usually gathered when the berries begin to change from green to red, and the berries are rubbed off by hand, spread on mats, and dried in the sun. They are afterwards winnowed, and then form the wrinkled and dark pepper-corns of commerce.

When the time arrives for plucking and curing, great care is necessary to attain the best results, for, in the wet season, the crop may be too soggy, and in the dry season become too woody and fiery, as ripening is destructive of flavour and aroma. Curing by artificial heat is the method in vogue on large plantations, but sun-curing, when properly done on matting, is better. The practice of "swelling the crop" is not uncommon among the Chinese and native planters in the pepper countries by the addition of wild pepper, as well as berries not akin to the pepper family; not to mention a modicum of sticks, stones, and dirt, but this fraud is generally tabooed by British and French planters, though dirt will adhere to the hull under the best system; therefore, crude pepper used at home should always be "shotted" in water, quickly washed, and the floaters rejected with the dirt.

If left too long on the tree the berries turn paler, but lose part of that aromatic, pungent, hot taste for which they are noted. In drying, the succulent part of each berry becomes contracted and wrinkled, the corrugations being much raised and describing a kind of elevated net-work; it is then also that it loses its redness and turns black. That which has been gathered at the proper time shrivels least, but if plucked too soon it generally becomes broken and dusty.

Black and white pepper are really both the same berries, the white being manufactured by removing the dark outside covering of the berry; but the black is more pungent than the white on account of the acrid resin, known as piperine, and a volatile oil, contained in the skin or fleshy part. Pure black pepper contains about 2½ per cent. of this crystallisable piperine and about 2 per cent. of the essential oil, with only 5 to 5½ per cent. of ash. Samples with more than this proportion of ash may be considered adulterated.

As with many other articles, the various growths and qualities of Black Pepper corns are easily judged when brought together, but difficult enough when alone; and there are very few persons who could correctly separate the various growths and identify each sort with certainty.

The weight of a handful is the usual mode of judging quality, the grades being technically known as heavy, half-heavy, and light corns.

According to Chevallier,

		grammes
100 Penang Corns should weigh about		6·249
100 Malabar Corns	ditto.	6·053
100 Sumatra Corns	ditto.	5·147
100 Trang Corns	ditto.	4·573
100 Tellicherry Corns	ditto.	4·507

but merchants consider Malabar is generally the heaviest. To increase the weight of the corns, they are sometimes steeped in brine for about 24 hours, but a close examination will detect the fraud.

Steel mills are found better than stones for grinding pepper; the stone mills developing considerable heat, and wasting much of the aroma, besides producing a "burnt" flavour.

In the ground peppers supplied to retailers, Malabar, Penang, and Sumatra are usually mixed, the first to give weight, the second strength, and the third, colour.

Ground Black Pepper is also now often largely made up from the *Pepper Shells*, or husks, obtained in preparing the White Pepper.

Pepper is one of the most wholesome and useful of the spices. With persons in ordinary health it has the effect of stimulating the stomach gently to the performance of its functions, and is particularly serviceable to persons who are of cold habit or who suffer from weak digestion. Used in moderation, pepper decidedly promotes the appetite and aids digestion, and, as to the quantity the system can take care of, as much as a spoonful is sometimes given in a little water in severe cases of flatulency. The natives of India highly esteem pepper as a stomachic, and make a strong infusion of it to drink by way of creating an appetite and to cure gout and palsy. They have also a method of making a fiery spirit of fermented fresh pepper with water, which they use for the same purpose, and also prescribe in cases of cholera morbus; a liniment for rheumatism is distilled from the berries, while the root of the vine is employed as a tonic, stimulant, and cordial.

Malabar pepper (which reaches England by way of Bombay) and Penang are considered the best. Good pepper has firm round corns, not too deeply wrinkled, and does not easily break or crumble in the hand; it is also heavy and skins readily in water. A yellow tinge on the outside pericarp betrays over-ripeness and consequent loss of strength; the inner seed should be hard, round, and smooth, and of greyish-brown colour.

Black Puddings. — F. *Boudins;* G. *Blüt Wursten;* Port. *Chorizos de sangue;* Sp. *Morcillas;* W. *Guaedogen.* These are made from pigs' blood and fat, with groats, herbs, and spice. The whole is usually enclosed in a piece of the intestine of the pig and boiled, but it is afterwards also fried. They are ordinarily genuine, but often prepared in small, close, and unhealthy dwelling-rooms; and as blood rapidly decomposes, they may become tainted before being cooked. Black puddings are mainly distinguished by the seasonings used in their preparation. In the *Cheshire* caraway and coriander predominate, while the *Salop* has none of the former and very little of the latter. The *Staffordshire* contains equal quantities of salt, pepper, marjoram, and pimento, with twice as much of thyme. The *Yorkshire* contains twice as much of marjoram and thyme as of pepper and salt, also a little savoury and lemon thyme. The *Stretford* is a highly-seasoned variety containing equal portions of salt, pepper, marjoram, mint, and thyme.

An average recipe for Black Puddings:—Boil 6lbs. of groats half an hour in a loose cotton bag, then empty them into a bowl, and while hot add 3 or 4 oz. powdered seasoning mixed as follows:—3 parts of thyme, 3 parts of marjoram, 1 of mint, 2 of salt, and 1 or 2 of black pepper. Some makers add 1 part of savoury, pimento, or coriander.

After well mixing the seasoning with the groats, add 6lbs. of leaf lard cut up in ½-inch squares and 2 gallons of blood. Stir well, fill into skins, tie, and then boil slowly about twenty minutes in water which has been coloured black by the addition of 1 oz. of logwood to each gallon of water. Some makers use soda to heighten the colour, but it is apt to make the puddings burst. In France beet leaves and onions are also used.

Black Rice. — A Burmese variety, grown in Chittagong, and known there as *Joomah Choul.* It is much more glutinous and nourishing than ordinary rice, being rich in albuminoids (9·2 per cent.) and in oil (2·2 per cent.), and thus approaches more nearly the nutrient ratio of a complete food. A pigment contained in the dark integument is identical with that to which is due the red colour of grapes, black currants, and many other fruits, flowers, and leaves.

Black Soap or **Farrier's Soap.**—A coarse kind of soft-soap, made from fish oils and caustic potash.

Sometimes tar is added, also iodine, bromine, creosote, etc.

Black Sugar.—See *Liquorice.*

Black Varnish. — (See also *Komo Black.*)—A natural varnish or lacquer, the product of the Burmese, Martaban, or other varnish trees, especially the sap of the *Melanorrhœa usitata*, which is a thick viscid grey turpentinish substance, which soon turns black on exposure and dries very slowly.

It is said nearly every vessel in Burma, whether for holding liquids or solids, is lacquered with this substance, as well as furniture, idols, temples, etc. Black varnish is also made from, say, 48lbs. asphaltum, 10 gallons boiled oil, 7lbs. red lead, 7lbs. litharge, 3lbs. white copperas, 8lbs. dark gum amber, fused, 2 gallons hot linseed oil, and 30 gallons turps. Boil the asphaltum, boiled oil, red lead, and litharge for two hours, then add the amber and boil again for two hours, or till a little mass when cooled may be rolled into pills. Lastly thin down with turps.

Blacking (for boots and shoes).—Da. *Skoesvarte;* F. *Cirage;* Ger. *Schuhwichse;* It. *Nero da rigner le scarpe;* Port. *Graxa;* Sp. *Betum;* Sw. *Skosvarta;* W. *Dû esgidiau, duad.* (See also *Harness Blacking, Liquid Blacking*, and *Shoemakers' Black, Brown-Boot Polishes*, etc.

Space will not permit all kinds of paste and liquid blackings to be described, but they are usually made of powdered bone-earth or ivory-black, sperm, linseed, or other oil, coarse sugar or molasses, vinegar, or sour beer, strong sulphuric acid (oil of vitriol), copperas, and sometimes a little gum arabic.

Each manufacturer has of course proportions and methods of mixing peculiar to himself; but generally all the materials selected are ground together in a paint-mill until the paste is smooth. The average percentages for Paste Blacking are:—

Bone black... ...	... 13·0
Molasses	... 68·0
Sulphuric acid ...	... 12·0
Soda	... 4·5
Fat or oil	... 2·5

A cheap and popular example.—1 cwt. lampblack, ½ cwt. soot, 46lbs. treacle, 1½ gals. of oil substitute, 32lbs. sulphuric acid, and 3 gals. of water.

The four first articles are mixed with a wooden spade, the acid is next diluted with water and then mixed up well in the other, covered over, and left for a day or two. It is then put into an enamelled copper and stirred well, while simmering for about 10 minutes. When thus "cooked," it is removed from the fire, cooled, and given a final stirring with the spade.

It is then ready for filling into tins.

For paper rolls or square packets the paste is spread into wooden trays, and stacked away to stiffen for a week or 10 days. It is finally cut up with a "plough" and wrapped.

Blackings made in this manner are always moist, shine as quickly as those made with the usual material, and after two or three applications give a softness to leather that other blackings do not.

The papers are prepared by soaking them in boiled oil, then a bunch of them are placed under a press to squeeze out excess of oil; and after being left in the press all night they are pulled apart, and dried ready for use.

Varieties of blacking free from sulphuric acid have lately come into the market, a highly bituminous schist being used instead of bone-black in their manufacture. These paste blackings are simply mixtures of say, fat 2·5, molasses 63·5, and black schist 34·0, with the occasional addition of an antiseptic. The black schist, however, loses about 20 per cent. on ignition.

There is more science in blacking than appears on the surface, and not every person knows why well "blacked" boots shine. The fact occurs through the blacking having in suspension myriads of tiny, angular particles of plumbago or "black lead." When spread out upon the boot, such a drying or oxidation takes place as to leave the crystals of plumbago—facing in all directions indifferently—involved in a very stiff "bog," as it were, of the agglutinating

medium. And in this state plumbago particles reflect such rays of light as fall on them indifferently in every direction, irregularly or dispersively, as it is termed. They wear the dull aspect so characteristic of dispersively reflective bodies. But now comes the function of the brush. This smooths down the jagged particles of carbon, stroking them into such positions that their more or less flat surfaces all lie in the same plane as that of the leather of the boot. Then regular or specular reflection can take place at these uniformly directed facets, and the boot begins to shine. The pleasing effect is still more heightened as the brush is continually applied, for quite impalpable atoms of plumbago are swept off from the residual hillocks or protuberances, and are deposited in intervening hollows, thus accentuating the smoothness of the whole.

Shoe-blacks in London were at one period styled the "Black Guards," but afterwards becoming a low set of rogues and cut-throats, the term "black-guard" began to be applied to any low ruffian.

One of the old City of London companies, yclept "*The Worshipful Company of Japanners,*" originated with shoe-blacks.

Throughout the middle ages blacking is not mentioned, and the boots worn were of the brown colour natural to leather, blacking only coming into use in the 17th century.

Although there is no great difficulty in making common blacking, it is quite a different thing to produce a high-class article, one that will yield the most brilliant gloss without injuring the leather. Charles Day & Richard Martin, London, first began blacking making in Tavistock Street, Covent Garden, then at 97 High Holborn, and now in the Borough Road. The firm has for over a century been turning out a type of blacking which has, so far, puzzled all imitators. We believe that firm was the first in England to commence as blacking makers only, and an old museum print, dated 1801, caricaturing Mr. Charles Day, under the caption of "A gloomy *Day* at Brighton," shows that he must have been almost as popular then as the modern firm is to-day. Many persons get their boots blacked without any regard as to what sort of blacking is being used, and the worst blacking being, as a rule, the cheapest, we have a ready illustration of the proverb, "Penny wise, pound foolish," for their boots are quickly spoilt and new ones required.

The enormous business now carried on by Day & Martin not only shows the lasting worth of a superior formula, even in blacking, but also testifies to an ever-increasing number of more thoughtful housekeepers all over the world, who are willing to pay freely for a superior article when they can get it.

To make new boots polish more easily, get some clean pipe-clay and make into a paste. Cover the boots all over the outside with it and let it dry on thoroughly; when dry, brush off with a clean brush. Then black all over with *good* blacking, use plenty of elbow grease, and you will have a capital polish.

An increasing amount of blacking is coming from France, Germany, and America. The black and brown polishes of a Boston maker also have secured a firm hold here; while several leading bootshops in London get their supplies from France.

Besides bottle blackings, a large quantity is imported in barrels from Germany and France, being finished and made up for sale afterwards. The solvents used include spirits, turpentine, and wood alcohol.

Special Firms.—Day & Martin, Ltd., London and Liverpool (see adv. end of book); Geldart & Co., Old Swan, Liverpool—telegrams, "Sapolis," Liverpool; C. Windschuegl & Co. (materials for), 1 Leadenhall Street, London, E.C.

Bladder Nuts. — See *Pistachio Nuts.*

Bladders for Lard, etc.—Easily prepared. Cut off the loose fat, wash the bladders in a weak solution of chloride of lime, and rinse in clear water.

when drying, blow them tight, tie the necks to keep them expanded, and hang them up.

They are very useful to tie over jars, pots, etc.

Blaeberries or **Bleaberries.**—Scotch names for *Bilberries.*

Blanched Almonds.—See *Almonds.*

Blanc-Mange Powders (pr. *Blomange*).

These are often made of dried sago-meal, adding to each pound 15 drops of essence of lemon and 12 grains of mace.

Some consist of five parts of cornflour to four of white sugar.

Special Manufacturers.—De Carle & Son, Fruit Drink Works, Norwich. Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices, from 50/- to £100. Catalogues from William Gardner & Sons, engineers, Gloucester.

Bleaching Powder.—See *Chloride of Lime.*

Blended Butter.—This industry, as introduced into Ireland from Cherbourg, by Squire Porter, an Irish landlord of Belle Isle, Lisbellaw, County Fermanagh, owes its origin to a great disparity in prices of ordinary Irish butter and the best Continental importations, and especially the butter coming from Cherbourg. The latter generally obtained 25 to 30 per cent. higher prices than the Irish. Thanks to the above indefatigable squire, what had long been attempted by individual butter merchants is now worked by local combinations of farmers for themselves. Fresh butter is bought in the markets at all the towns within 20 or 30 miles of Bantry. It is classed 1, 2, and 3 in the markets, and each grade packed in large block tin boxes about two feet every way covered with butter paper to keep it clean. These tin boxes are put inside larger wooden boxes, with lids, each box holding about 200lbs. of butter.

On arrival at the mill, ordinarily the evening of the same day, it is re-examined carefully by experts, so as to correct any error that may possibly have occurred at the market examination, for one bad lump would spoil the lot. After this final classification each batch is separately and thoroughly washed in a machine with rollers. If the butter be hard it is tempered with warm water, else it would be lumpy and streaky, and would not take the dry salt evenly and keep well.

The butter is then passed to the blending machine, which is within a few feet. This machine is raised in the centre, and the rollers taper to the centre of the table, so that the butter is not more worked near the centre than the outside; and is capable of blending 500lbs. at a time. If additional colouring is considered desirable, it is added here. When well blended the butter is placed in a large trough near the salting machine, a sufficiency of salt is spread over the butter by the experienced operative, and it is then passed twice through the salting machine (a French vertical machine), which completes the process.

The butter is now ready for packing in small rolls or in firkins or boxes. A hand machine shapes and weighs rolls of 1lb. or 2lbs. each. As the perfectly blended product is put on rail or boat the morning after each market, the whole business only occupies a day.

The advantages of these blending mills over creameries are:—(1) The butter milk is kept at home by the farmer; (2) the farmer's wife or daughter may still make the butter in their own dairy, in accordance with given rules, so that it may be readily classified in the local market; (3) the cost and trouble of conveyance of the fresh milk to the creamery is thus avoided.

Blending Mills or "*Grading factories*" of Brittany and Normandy may be owned either by an individual or a company: and the agents in France often women, attend all the local markets within a reasonable distance. The farmers or butter makers of the district bring to these markets the butter churned at home, *uncoloured* and *unsalted*, and in the lump, simply wrapped in a clean

cloth in a basket. The agents practically fix the prices of the different grades of quality, which vary in number, according to the size of the factory.

The French butter-makers also lay themselves out for winter production, and the winter product is greater than the summer. But the lateness of the seasons in their districts enables winter dairying to be carried on under more favourable conditions than is possible in the United Kingdom, and this is an important advantage. The French butters, fresh and unsalted, are therefore very popular in London and in the South of London districts.

Blended Teas.—(See also *Teas.*)—It is only since 1882 that the blended tea systems have become really important features in the trade. It may be said to have sprung from the practice of mixing Indian and Chinese sorts. By all appearances it is destined to become more and more popular.

The old school of wholesale merchants were at first, and many of them still are, much opposed to the policy of supplying retailers with teas ready blended. They prefer the retailer continuing on the old lines of buying and stocking several kinds, and making up his own mixtures for the various canisters. Such a retailer is always likely to be wanting one kind or another, and is consequently a better customer than one who buys teas ready blended, and only in small quantities as required. No doubt many retailers are excellent judges of tea, who know what and where to buy, and how to mix, but such are only few in number in comparison with the great majority who have not had the opportunity of acquiring similar proficiency in the art. It must be obvious the latter in bargaining for separate kinds are no match for wholesale firms and travellers who have made teas a life study. But in the case of ready mixed teas the scientific difficulty of mixing properly devolves on the wholesale blenders. This is the chief *raison d'être* of the blended tea system, and instead of the retailer, who has nowadays a vast number of other articles to purchase and to sell, wasting his time liquoring and haggling over scores of samples of tea, as often deciding wrongly as rightly, possibly oftener, and instead of having to lay out his cash, or credit, in securing a large stock of many sorts and qualities, all he has now got to do is send the wholesale tea blenders a sample of his 1/-, 1/3, 1/6, 2/-, or 2/6 mixture and inquire the prices at which they (the blenders) can match the sort required; when he gets it he must, of course, see that it is equal in quality and flavour, for, as practical grocers well know, consumers can get so accustomed to any tea of fair quality as to think all others unequal to it. By so managing the ordinary dealer can now buy tea ready blended by those who understand it best, at much less cost. The business is indeed much simplified; the tea may be bought as required, and sold before it becomes stale and flavourless by exposure or age. This last point becomes accentuated when we reflect that nearly all the tea now coming to this country, instead of being Chinese or Japanese tea, and improving with age, is of Indian or Ceylon growth, and well known to deteriorate every month it is kept; so not only is it found prudent to buy teas ready blended, but further to buy these blends fresh as possible.

As to how to blend teas, that is an art we can scarcely here enter upon. Three or four books on the subject have been written with copious instructions, and those who desire to pursue the study will do well to procure "*Tea and Tea Blending*," 8vo., price 5/-, published by Eden Fisher & Co., 50 Lombard Street, London, E.C.; or "*Walsh's Tea Blending*," pp. 104, price $1, published by J. M. Walsh, tea expert, Philadelphia, U.S.A. Much valuable information may be gathered from both of them. The classes of most teas may, however, soon be recognised at sight, and the comparative merits of a few samples more or less closely ascertained by anyone after infusing for five minutes a small quantity (the weight of a sixpence) of each in four ounces of boiling

water in the small covered white sampling pots made for the purpose, and then carefully tasting and examining each as to colour, strength, body, flavour, and aroma, etc. The samples should be tested in the water of the district where the tea is to be sold and used. The appearance of the wet leaves and the sediment is also to be noticed. But their current values can only be determined after careful trial by skilled tea-tasters with sensitive and regular palates. A Pekoe may be readily distinguished from a Souchong, but the Souchong of certain planters or districts may have more value than other Pekoes. No strict rules can, in fact, be laid down how to judge teas, but with black teas generally the darker the liquor the stronger the tea, and the nearer the colour is to a salmony brown the better the flavour. On infusion it should emit more or less of subdued fragrance, and in taste should be mild, bland, and sweetish, with an agreeable astringency.

The dignity or *amour propre* of many old grocers revolts against the idea of buying ready blended teas, and this resistance is, of course, encouraged by the adroit traveller and others who benefit by it, but there are various features of the system well worth deeper consideration.

A grocer's business reputation among his customers depends largely on his teas, and uniformity of each blend is of primary importance. His 1/6 tea will always be the same, and so should every other quality. The customer expects to find it alike all the year round. But it is practically impossible for an ordinary retailer who blends his own to ensure exactness. He cannot conveniently always blend alike. His stocks are not uniformly fresh; some sorts have grown old and flat; others are probably fresh; and the result is an observable variance in strength or flavour, which zealous consumers will soon notice. Professional blenders on the markets have much better opportunities of selection and devoting their whole time and skill to the business of blending and matching, it is obvious these are advantages much in their favour. They know best where to buy, how to buy, and how to blend.

There is now a spirited competition among wholesale tea blenders. Houses of first-class repute now blend teas, and will sell for cash one or two chests cheap as ten or twenty, so that the single-shop retailer may really buy his teas almost as well as the largest firms.

Special Firms.—Brooke Bond & Co., Ltd., 17 and 18 St. Dunstan's Hill, London, E.C.; Cave, Johnson & Co., White Hart Court and Alderman's Walk, Bishopsgate, London, E.C. (ESTABLISHED 1879); pioneers of the wholesale Blended Tea Trade, and supply "Matchless" Blends from 1/- to 2/4 (duty and carriage paid); Morris & Jones, 13, 15, and 17, Sir Thomas Street, Liverpool, also sole agents for the "Household" Tea Co.'s blends, and the "Wungacherra" Tea; Spencer, Turner, & Boldero, Lisson Grove, London, N.W. (see *High Caste Ceylon* and *Silver Packet Teas*).

Bloater Paste, Potted Bloater, etc.—The bloaters used for above require much care and judgment in their selection. They should be plump and well smoked; those technically called "shot" fish, or spawned, being poor and of inferior flavour, are undesirable.

The fish are first skinned (the heads and tails thrown away), and then minced very fine by hand or in a machine. Lard and spices are next added, and the whole well mixed, after which it is filled into fancy pots, patent jars, or tins, and hermetically sealed down, sometimes with lids of soft tin, which may easily be cut with a pocket-knife. These preparations, however, will not keep good very long even then. They are often found wrong on being opened, and should not be kept in stock long.

Bloaters.—A name given to herrings when they have been slightly smoked or "bloated," and are intended to be eaten soon afterwards.

Bloaters are reckoned in baskets of 150 to the basket. Yarmouth is celebrated for its bloaters.

Block Juice.—See *Liquorice Juice.*

Blood Oranges. — These come mostly from Malta, Sicily, and Spain, and are remarkable for the peculiar blood red or mottled crimson colour of their pulp and reddish rind. Some people fancy, and have gravely asserted, that this is owing to the trees having been grafted on to pomegranate stocks, and that these hybrids are often crossed and recrossed till some of the fruits show only slight traces of the red colour; but Mr. Neville-Rolfe, H.M. Consul in Naples, declares this to be a complete fallacy. When grafted, both fruits—oranges or pomegranates—retain their original quality, and neither borrows anything of the other.

Palermo Bloods are almost the latest in the market, not arriving till Spring. Malta furnishes abundance of oranges, but they do not keep so well as ordinary Spanish or Portuguese. These oranges readily take a flavour from any strong smelling substance near them, so should never be placed near onions, etc. When scarce and dear, pedlars have been known to prick the skins of ordinary oranges, and then subject them to a bath in a solution of Rocelline, the scarlet of Biebrich, so as to pass them off as "*Bloods.*"

Bloom or **Sun Raisins.** — These raisins, so called from the species of grape used, are dried on the vine in a similar way to Muscatels, but consist of a different kind of grape. They owe their name "bloom" to their blue glaucous surface, and, like Muscatels, are dipped in potash lye to soften the skin, favour the drying, and impart a gloss. They are imported mostly in boxes from Malaga, a city and sea-port in the south of Spain.

Blubber. — Da. and Sw. *Tran;* Du. *Thraan;* Ger. *Thran;* It. *Olio di Pesce;* Port. *Azeite de Pixe;* Rus. *Salo Worwannoe;* Sp. *Grassa.*

This is whale fat found between the skin and the flesh, about 6 inches thick. The use of blubber in the fish seems to be partly to poise the body and partly to keep off the water at some distance from the blood, thus keeping the fish warm in the coldest seas. Blubber is usually imported in casks and made into train oil. Average yield 2 to 4 tons from each whale.

Blue.—F. *Bleu;* G. *Blau;* It. *Azzur;* Sp. *Azul.*

The various preparations of blue are referred to under their respective names. There are three different sources of origin: Cobalt, Indigo, and Ultramarine, but the substances made up in several forms and used in the laundries as blues are all compounds of ultramarine, some being natural and some artificial. See Azure blue, Berlin blue, Blue Ochre, Cobalt blue, Indigo blue, Laundry blue, Liquid blue, Navy blue, Prussian or Royal blue, Saxony blue, Smalt blue, Soluble blue, Steel blue, Ultramarine blue, Washing blue.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

For all kinds of blue, apply to Keen, Robinson & Co., Garlick Hill, London, E.C., makers of Keen's "Oxford" Blue.

Blueberries.—Same as *Bilberries.*

Blue Mountain or **Golden Rod Tea.** — An infusion of the leaves of the *Solidago odora.*

Blue Ochre, or **Native Prussian Blue,** is a hydrate of iron, a light and permanent colour, but not in much request.

Blue Veiny Cheese.—See *Dorsetshire Cheese.*

Boar's Head. — The boar's head has been for ages in repute in the halls of the great for its flavour when roasted and stuffed with nutritious and appetising adjuncts. Even roasted wild pigs, so fashionable in the Norman and early English periods of our history, are still heard of; but most of the Wild Pigs and Wild Boars' Heads of the present day are obtained with less prowess and

delay than were necessary in the middle ages. (See *Pigs.*)

Bocal.—A French glass jar or vase without neck, in which preserved fruits, such as cherries in brandy, pickles, sweets, etc., are packed for sale. There are litre bocals, half bocals, quarter bocals, and large 4-litre bocals.

Bock-beer. — See *Beers.*

Bodega. — The Spanish name for a large wine cellar on a level with the ground.

Boer Tea or **Cape Tea.** — These are infusions with tea-like fragrance, made at the Cape of Good Hope from the leaves of *Cyclopia Vogelii.* The leaves and tops of two other species of this leguminous shrub are also used in South Africa as tea to promote expectoration, viz.: *C. genistoides,* called "Honig Thee," and *C. latifolia,* called "Bush Tea"; also the leaves of *Borbonia parviflora,* known as "Stekel Thee."

Besides the above, there is also a "Boer Tea" prepared in New Holland from the plant *Correa alba,* of the natural order *Rutaceæ.*

Boha.—A species of Turkish brandy obtained from dates, and exported from Tripoli in earthen jars known as *goul-goul.*

Bohea, Bohe, or **Bou.**—Any sort of inferior black tea, poetically named after two ranges of hills called Woo ye, Wu-i, or Bwi-i Hills, in the province of Fuhkien, China, where black teas are largely produced, and whence tea was first exported to England in 1666. The name was also given to the latest gatherings (September) of tea grown in other districts, but has now become almost obsolete.

The low-priced black teas are all mixed together and form the bulk of that exported from Canton.

Being made up of all sorts of common leaves, broken, flat, and of various colours and flavours, the ruddy infusion is generally insipid.

Boiled Oils or **Drying Oils** are for mixing with paints. They are prepared by boiling a small quantity of oxide of lead, litharge, white vitriol in linseed or nut oils till it is dissolved. The best oils for this purpose are linseed, poppy, rape, and walnut. Boiled oils may be much improved in brightness and clearness by exposure to the light of the sun for a few weeks, or by passing them through coarse, woollen, filtering paper. (See *Oils.*)

Boiled Sugars.—F. *Bonbons Anglais.* The lowest priced boiled sugars are, of course, those made from the commonest or cheapest sugars, and without the addition of butter or much flavouring essence.

Toffees and butterscotch are usually made of brown sugar, but the butter necessary in them, if *good,* carries the cost rather high.

Acid Drops, if of good colour, strong of acid, and well-flavoured, are also higher priced on account of the tartaric acid and the lemon flavouring.

Hand-made goods are, however, usually the most expensive sorts of boiled sugars, such as Rocks, Striped Sticks, etc., and particularly those sticks with names, pictures, stars, honeycomb, or other marks running through their whole length.

It would be futile to enter into length detail how each kind is made, and how each form differs from another in colour, shape, and flavour.

In making them much depends on the quality of sugar used, the length of time the sugar is boiled, the amount and quality of the butter, essences, etc., but most of all depends on the skill or ability of the workman.

Probably in no other trade are there so many "duffers"—men who profess to be efficient sugar-boilers, but who are practically only sugar-*spoilers.*

It is doubtful whether one "sugar boiler" in a dozen is really an efficient and reliable workman.

In the boiling of sugar different degrees of heat are necessary, and sugar boilers have long had conventional terms

of their own for denoting these degrees, which are rather curious :—

The "Pearl" is a name given to the form sugar usually assumes at about 220°.

The	Small Thread	228°
,,	Large Thread	236°
,,	Blow	240°
,,	Feather	242°
,,	Small Ball	244°
,,	Large Ball	250°
,,	Small Crack	264°
,,	Hard Crack	284°
,,	Caramel (*Burnt Sugar Colouring*)	360°

But it must be noted that in boiling sugars the actual degree of heat is not a reliable guide, some sugars being more affected by heat than others.

Some sugars, in fact, become pearly at 215°, while others may require 225°, so that it would be misleading to say sugar for such or such a purpose should be boiled to 220°. It is, therefore, more convenient to say it must be boiled to the "Pearl"—*i.e.*, till the sugar in the pan assumes a *pearly* appearance. If it be further boiled to about 228° it assumes what is called the *small thread*, that means if the tip of the forefinger be dipped in the sugar and then brought in contact with the thumb there will be noticed on again parting them a fine thread of sugar, and so are all the remainder of the above technical terms accounted for.

To prevent sugar turning grainy during the boiling process it is necessary to "kill" it with a little acid of some kind. An ounce of cream of tartar for 28lbs. of sugar is an average proportion.

When the sugar has been boiled to the proper degree, it is poured on to a slab sprinkled with a little oil and starch to prevent the sugar sticking. It is here flavoured, and when of the proper consistency is taken to the drop machines. A row of these machines stands along the centre of the room. The essential portion consists of two brass rollers, containing semi-moulds placed one above the other, and so arranged that the upper set coincide with the lower to form complete moulds. These rollers move in reverse directions, and as the soft mass of sugar passes between them, complete casts are made in the sheet. When hard, the individual drops are broken off. The moulds are all manner of shapes and sizes, from the common pear to the corrugated raspberry.

Boiled sugars, such as butterscotch drops, toffee, etc., cannot be made properly with margarine, the vegetable oil which enters so largely into the manufacture of that article not being absorbed by the sugar in boiling, hence it all settles on the surface of the goods and only gives them a nasty greasy taste and appearance.

Many manufacturers now use various proportions of liquid glucose along with their sugar, especially for hand-made goods, it being more economical than cream of tartar for killing the grain and also helps the pliability, but if used too profusely the sweets will soon go sticky.

The nomenclature of boiled sugars and other sweets is almost unlimited and somewhat confusing.

"Brandy-balls" would suggest that such articles contained alcohol, but practically such is not the case. In fact, Brandy-balls were first introduced into the trade by a teetotaler. He wanted to wean people of the craving for spirits, so he used extra strong peppermint flavouring, and called the product brandy balls. Foreign-made sweets sometimes contain a little diluted alcohol, but English makers use flavoured syrup free from spirits.

It is surprising how few retailers know that all boiled sugars should be kept well corked and in a dry place, but not exposed to the sun.

Thousands of bottles of sweets are spoilt every year by being opened and replaced on the shelves loosely or imperfectly stoppered, or without being closed at all. The result of course is, the air partly melts the sweets, they stick together, and the bottle is cracked or broken in trying to get them out.

Everyone who has to sell boiled sugars should learn the proper way to manage sticky goods, and the sooner it is done the better. Breaking bottles is costly, and no one will accept cracked ones. The bottle must *not* be knocked on the counter, neither must a shop-knife or other instrument be put into the bottle to loosen the contents, but when the stopper or cork has been withdrawn the bottle should be held on the left hand, and with the open palm of the right hand the mouth of the bottle should be sharply slapped in such a manner as to *drive air into the bottle* to "start" and loosen the sweets. There is a knack in doing this most effectually, and the novice should get some experienced person to show how it is done.

If the sweets are too firmly stuck together to be loosened in this way the whole bottle should at leisure be gently warmed in water till the sweets soften sufficiently to be extracted without breaking the bottle.

Such sweets may then be mixed and rubbed up in a little crushed sugar and sold as cheap "crystallised sweets."

Bole Armenian. — See *Armenian Bole.*

Bologna Sausages. — (See also *Mortadella.*)—These celebrated Italian sausages are made of large size from bacon, veal, and pork suet, chopped fine, or beaten into a pasty mass, and stuffed in large thick intestines. They are sold ready for the table, and are eaten without further preparation. They are generally used as a *hors d'œuvre*, and the Bolognese entertain a romantic adoration for this kind of sausage, declaring it to be "God's own food."

Bologna Ham.—See *Hams.*

Bologna Wines.—At Bologna they boil most of their wines, which are then called *vino cotto;* the unboiled they call *vino crudo.* They are nearly all sparkling sorts, and in their natural state effervesce like champagne.

Bombay Ducks. — See *Bummaloe Fish.*

Bommes Wine.—A white French wine, known as one of the *Sauternes*, produced in the Bordeaux district. Prices about 25/- a dozen in England.

Bon-bons.—Bon-bon is a reduplication of the French word *bon* (good), hence *bon-bons* is really equivalent to "goodies," "sweets," "sugar-plums," or "sugar confectionery."

Bon-bons Anglais is a French name for "sugar confectionery."

In England the term bon-bons is, however, confined to sweets and mottoes made up in fancily-folded paper of brilliant colours and adorned with gilt or pictorial ornaments. Many of these bon-bons are very elaborately and artistically designed and command a brisk sale—especially during Christmas and other festive occasions.

Bone Black.—See *Ivory Black.*

Bone Soap. — A soap made from cocoa-nut oil mixed with jelly from bones.

Bontia.—The wild olive of Barbados.

Books, Periodicals, etc., relating to Grocery and Allied Trades, see *Trade Papers, Books,* etc.

Boot Polishes. — See *Blacking, Brown Boot Polish,* and *Liquid Blacking.*

Boot Powder. — This usually consists of French chalk reduced to a powder by scraping or grating and coloured to fancy.

Used to facilitate the "getting on" of new or tight boots, a little of the powder being rubbed on the inside of the back heels, and insteps, or the powder may be sprinkled in the interior of the boot.

Boot Top Powder (pink).—Recipe: Mix 1 oz. oxalic acid, 1 oz. alum, ½ oz. cream of tartar, and ½ oz. isinglass; colour pink, with cochineal or annatto; and then boil the whole in a quart of water for 10 minutes.

Boracic Acid. — (See also *Antiseptics, Preservatives*, etc.)—Dr. Bond, of Westminster Hospital, and Professor Redpath, argue that it is perfectly harmless as a food preservative. Nearly 3,000 tons are produced yearly in the provinces of Pisa and Groseto, in Tuscany.

In the hands of a scientific man, the introduction of such a chemical in proper quantity might be perfectly safe, but danger arises when an article of food, passing through the hands of several middlemen, is heavily dosed by each; and, after all, there is the fact that if these antiseptics preserve goods before they are eaten, they also hinder digestion afterwards.

It is a comparatively easy thing for the grocer to find out for himself whether any of the articles he supplies contain boracic acid, although it is impossible for him to determine the amount without delicate chemical apparatus and some analytical training. All that is required to detect the presence of boracic acid is to soak the material for a few minutes in methylated spirit and apply a light; if boracic acid is present the alcohol will burn with a characteristic green flame. Borax, which is a compound of boracic acid with soda, can be detected in a similar manner, the addition of a few drops of strong sulphuric acid being made to free the boracic acid from the soda.

Borate of Lime.—A name for the crude material from which borax and boracic acid are made.

Borax or **Tincal.** — F. *Borate de Soude;* G. *Natriumborate;* It. *Borace;* Port. and Sp. *Borax;* W. *Math o halen.* Also chemically called borate or biborate of soda.)

A white crystalline native salt, or solid compound of soda and boracic acid, found in certain lakes in Persia, Thibet, Peru, Ceylon, and Chili, also in Nevada, California. Large quantities are obtained from the marsh lands of Italy.

The Crude Borax ordinarily forms a fine saline incrustation on the surface of certain sea shores, and is also found, more or less pure, at the bottom of several lakes and valleys in most of the volcanic regions.

It assumes one of two forms, either large hexagonal prisms or regular octagons.

In Chili, around Antofagasta, borate of lime is found in *nodules*, some of which contain over 40 per cent. of anhydrous borax, and the finest *frit* has been made from it with very little trouble. Twenty years ago the price of borax in England was about £100 a ton, and the world's produce was only about 3,000 tons. Now the consumption is about 50,000 tons, and the price only about £20.

Our supplies since 1864 have mostly come from Death Valley, California, and by boiling and crystallising this product it is soon converted into "*Concentrated.*" Pure borax is colourless, has a greasy feel, soapy smell, and sweetish alkaline taste. When heated it melts and runs into a sort of glass, and from this *false gems* are commonly made.

It is soluble in twelve times its own weight of cold water, or half its weight of boiling water. The word *Borax* comes from the Arabian word *burak;* and *Tincal* is an Arabian term given to the crude or impure borax found on the borders of lakes there, covered with an earthy, greasy coating, and of very rank smell. Borax is also extensively made by boiling together, in proper proportions, boric acid and carbonate of soda.

One of its chief uses is to facilitate the enamelling of metal vessels, signs, show tables, etc., glazing china and earthenware, and in brazing, soldering gold, silver, etc.

It is also largely used in leather dressing, glass-making, candle-making, photography; as a stiffening by calico printers, hatters, laundresses (partly in place of common soda), makers of insect powders, throat lozenges, etc., and for preserving milk, butter, meat, fish, and other tinned goods.

Many authorities, however, declare that a too liberal use of borax and boracic

acid in foods is injurious, that it sets up indigestion and diarrhœa. Dr. Stevenson, of Guy's Hospital, considers 0·25 per cent. of boric acid in butter, and 0·1 in milk quite innocuous and sufficient to preserve articles for a reasonable time; but milkmen and others are apt to employ it very carelessly, and often milk is twice dosed.

The great pork packers in America use two or three thousand tons a year. Its use in preserving hams and bacon would appear quite harmless, inasmuch as it is only used for covering the outside of the meat after coming out of pickle, and is usually washed off before use.

In fact, it is employed in 20 or 30 different trades, and is growing in importance.

It is a natural antacid, that is to say, it soon kills or neutralises all sourness.

A small piece of borax sucked is an excellent cure for sore throat. In the sick room, too, it is invaluable for sores, burns, bad ears, and all kinds of wounds, also as a disinfectant. Mixed with honey, it is known as *Mel Boracis* (Borax and Honey), and used as a remedy for the "thrush" with infants, and as a salve for skin eruptions. To make this properly, mix 64 grains, or one heaped-up teaspoonful, of pure powdered borax with one ounce, or two dessertspoonfuls of best honey.

Borax Water, an excellent wash, is prepared as follows:—Take of borax a penny packet, or 1 ounce, boiled water (allowed to cool) a pint and a half. Shake together—the water will dissolve about one per cent. of the borax; the remainder will fall in fine white powder to the bottom of the bottle. As the clear borax water is used, you have merely to fill up the bottle again with cold water (water that has been boiled is best), and this process can go on until all the borax has been taken up, which will not happen until you have filled up the bottle at least a dozen times. So, for twelve wine bottles of borax solution, the cost will be the small sum of one penny. This solution is exceptionally good for mouth wash, teeth, throat, the eyes, the skin, and for all toilet purposes.

Borax is sometimes adulterated with carbonate of soda.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

For pure English borax, apply to the Punch Polish Co., Hick Street, Birmingham (F. Cooke, proprietor).

Borax Soap Powder.—A kind of dry soap, usually made of about 5 parts powdered curd soap, 3 parts soda ash, 2 parts sodium silicate, and 1 part crude borax.

All well dried first, then mixed thoroughly and sifted. (See also *Washing Powders.*)

Bordeaux Wines. — (See also *Clarets.*)—Bordeaux is certainly the most important wine city in the world. The principal wines of the district include those of South-west, Gironde, Dordogne, Landes, Basses and Hautes-Pyrenees, Gers, Haute Garonne, Lot, Lot et Garonne, Tarn, Tarn-et-Garonne. The wines of the Gironde however are, more especially, considered the Bordeaux.

They are classed in four categories according to the site of vine lands:—Graves, Cotes, Palus, or Entre-deux-Mers.

Graves Wines include Chateaux-Margaux, Laffitte, Aubrion, Latour, etc., ect.; *Côtes*, St. Emilion, Fronsac, etc., etc.; *Palus* (signifying alluvial soil) Mont Ferrands, Qunsacs, etc. Of the *Entre-deux-Mers* (the district between the Garonne and the Dordogne) the best known are the wines of Brane, Sauveterre, and Cadillac.

The following are arranged in order of merit:—

Red Wines—Chateau-Lafitte, Chateau Margaux, Chateau-Latour (all known as Medocs), Haut-Brion, Branne-Mouton, Cos-Destournelles, Durfort, Gruan, Larose, Lascombe, Leoville, Mouton, Fleuret, Pichon-Longueville, Rouzau, Calon, Chateau-Giscourt, Chateau d'Issam, Chateau-Lagrange, Palmer, etc.

White Wines—Sauterne, Rabeaud, Latour-Blanche, Pupaguey, Bommer, Bayle, Rieussec, Barsac, Preignac.

Boric Acid. — A popular antiseptic extracted from *Borax* (which see).

Borecole or **Cow Cabbage.** — See *Cabbage.*

Bosan. — An oriental beverage obtained by boiling millet. It is very popular in Turkey.

Bosch Butter. — The conventional name originally given in Holland to what is now called *Margarine.*

Boschjesmans-thee. — A favourite drink among the bushmen, besides having a beneficial effect on coughs and asthma. Is derived from an amyridaceous shrub, *Methyscophyllum glaucum.*

Bosnian Plums.—(See also *Prunes* and *Plums.*)—The commercial name of the commoner kind of dried plums or prunes of Bosnia, Herzegovina, and Slavonia. Brecka, on the banks of the Save, is a great market for them, and about three parts of these plums are sold there. The superior quality is known as "Sultana," 70 to 85 plums to the ½ kilo. In the two first-named countries, plums form the basis of three native industries; cooked, they form without sugar a very rich jam or compote called "bestilj" or "lekivar"; pressed, fermented, and distilled, they supply "slivovitza," a drink which possesses a very fine perfume, and is greatly appreciated by the Slavs; dried, they become the *prune,* known throughout the whole world. In 1890 the export reached 17 million kilos., worth over £325,000; but it has since risen by leaps and bounds to about 40,000 tons annually. They are not, however, always of the same quality, sometimes being deficient in flesh and will not keep.

The plums are dried in ovens or 'pumiscas," and divided into six categories according to the size of the fruits. The first includes plums weighing 75 to the ½ kilo., then come 80's, 85's, 90's, 100's, while the sixth quality may be 110 or more to the ½ kilo.

The first quality is packed in rough boxes containing 5 to 10 kilos., and the other qualities in sacks or barrels. They mostly arrive in England packed in half-cases of 56lbs.

The fruit must be gathered only at a certain stage of ripeness.

They are sized by means of sieves. Improved French ovens have latterly been introduced for drying these plums, and they are now little inferior to best French plums.

Plums are the staple industry and export of Bosnia. The poorest peasant usually has a few plum trees by his hovel, and wealthy landowners never think of planting any other kind of tree by their country homes. The dried product is almost exclusively exported from the Possavina and the northern districts, the cost of transport being too heavy from the interior.

The export trade is mostly in the hands of German houses at Berlin, Ratisbon, Monaca, etc. Apply to Wm. Field & Co., Ltd., importers, 66 High Street, Hull.

Botanic Beer, Herb Ale, etc.—See *Non-Alcoholic Beers.*

Botany Bay Tea.—Prepared from the *Smilax glyciphylla.*

Botargo. —F. *Boutargue.* (Called in Provence "*Boriargues.*")

A sausage-paste or condiment made on the shores of the Mediterranean and the Black Sea from the roes of a species of grey mullet (*Mugil cephalus*), and white Russian sturgeons. The eggs are salted, crushed, reduced to a paste, and then dried in the sun or smoked. Sometimes spices and other ingredients are added. Its consumption is very general throughout the Mediterranean. Sold in small glass vases, kegs, etc. The best comes from Tunis and Alexandria, salted and dried like *Caviare.* This kind is made from the roes contained in the two oblong membranous pouches in the mullets common to the Lake Menzaleh.

It is used as a *hors d'œuvre,* eaten with bread and butter, olive oil, and lemon juice, and is principally intended as an incentive to thirst.

Bottled Ale and Stout. — See also *Ale*, *Porter*, etc.)—Grocers should be careful where they buy these. They are often offered wholesale at rates which cannot pay the honest bottler. It has been proved dirty bottles are often used, that the bottoms of ale casks are mixed off in stout, that Guinness' Stout and Bass's Ale are often mixed with cheap and inferior kinds. It is also said that "brewers' returns," cloudy or sour beers, thick and nasty cask bottoms, drainings from the bar, including froth, both of jugs and glasses, spent hops, soda water, slops, etc., often find their way into casks and ultimately fall into the hands of unscrupulous old-beer dealers and ale and porter bottlers.

Ale intended for bottling should be stored in the cellar some time before it is required to be bottled, otherwise there is no security for its being bright and in fine condition. The ale cannot become bright until it has entered into fermentation in the cask, and, therefore, when it is received, some time (more or less according to the state of the ale or the temperature of the cellar) must necessarily be allowed. If, however, the newly-brewed ale be effervescent it will usually become bright when it has stood from two to six or seven days, while ale that has been in the cask a considerable time does not become transparent so quickly and may, in some cases, require rest for a month after having been moved.

In cold weather beer can be drawn from the hogshead and bottled as soon as it is received, but in warm weather it foams, so that it may be necessary to insert a porous peg and to keep it several days in a cool cellar, if it has got warm in transportation, before tapping.

The bottles must be very thoroughly washed each time, before filling, with warm water and soda, then rinsed repeatedly with cold water until all the soda is washed out, to prevent the beer tasting of soda.

It is very important to use clean, dry bottles and good corks.

No ale is fit for bottling unless it is perfectly sound, brilliant and sparkling, but not in active effervescence. It should flow freely from the cask, without air being admitted to it, but not so as to cause frothiness in the bottles. The taps should reach nearly to the bottom of the bottle, so as to prevent the atmospheric air from mixing with the ale. The bottles should be corked immediately, and set upright on end in a cool cellar. With a board or two between each layer, they may be stacked up any reasonable height.

In summer they should be allowed to stand four weeks and in winter eight weeks, and the beer should then be in the pink of condition.

Every beer has some sediment. When the bottle stands up this sediment becomes attached to the bottom of the bottle, so that if the beer is poured out carefully all except the very last will be clear and free from turbidity.

Stout or Porter need only stand three or four days in the hogshead and about ten in bottle before using.

In filling the bottles the old way, a wooden spigot is used with a piece of rubber tubing attached, that reaches to the bottom of the bottle, so as to prevent foaming as far as possible. The bottle is immediately corked, so that the carbonic acid may not escape, and the cork driven down with a small wooden hammer. Some add artificial gas to the beer, but that is not wise. Others use screw-stoppered bottles, which may seem a saving, but the public, as a rule, prefer the old-fashioned cork. Great attention must be given to the cleanliness of the rubber tubing and the spigot, rinsing them with a soda solution before each time of using—and afterwards, too.

Great care must always be devoted to the corks, when corks are used. Those that have been bored or broken must never be used under any circumstances. Whether new or old corks are used, they must be soaked in warm soda solution and repeatedly washed with cold water until perfectly cold. It is far better, however, not to use corks that have already been used once.

When ale is bottled it should be kept in a cool cellar, say 55° to 60°F., til

required for use; but if it is found that the ale is not active enough, the removal to a warmer situation (which should not exceed 65°) will excite a more lively fermentation.

Porter, as sold in cask or bottle, is usually a blend of a new and old brew, and to judicious blending is due the characteristic flavour of several well-known brands.

By way of forcing condition in porter many bottlers use a small quantity of malt flour, brown sugar, fresh wort or "chipped" wort—*i.e.*, wort partially fermented—but, except when rapid consumption is certain, the use of these materials cannot be recommended, as they frequently induce acidity and ropiness. Fresh wort taken from the mash tun or refrigerator is, perhaps, the best forcing material; the others are all objectionable. Malt flour contains crude nitrogenous matter; brown sugar usually swarms with minute organisms, and chipped wort contains yeast and diseased ferments.

When the porter is bottled, some bottlers bin it away, and in winter keep up a forcing temperature by means of a fire or steam pipe till it gets into condition. This can hardly be said to be a good plan, as, when the porter is removed from the warm bins to the retailer's shop or bar, where the temperature frequently is very low, it is almost certain to lose its artificial condition, and go perfectly flat and undrinkable.

Porter needs more careful watching than ale, for as soon as it becomes ready for drinking it should be sold, and have a quick consumption, or it will become hard, and people will then say it is *sour*.

Such porter had then better be taken back and mixed off with the next bottling.

In conclusion, porter and ale to be bottled should be placed in a temperature of 50° to 60° for a number of days, until from quiet and temperature it is in a condition for bottling. Then, whether it be beer or porter, the bottling may or may not be done at a filling machine, at which four to eight bottles can be filled at a time. This method of putting the goods in condition by quiet and temperature and by filling at a machine secures full bottles, well charged with gas and without foam. There may, however, be a little more waste or spilt beer than if run straight into the bottles.

Bottled Fruits, etc.—These are much the same as "Canned Fruits," but are more tempting to the eye; the transparency of the polished glass enhancing the beauty of the respective fruits. The object, of course, is to keep the fruit as fresh as possible, and suitable for baking in pies, puddings, tarts, etc., during the winter and early spring, when fresh fruit is generally very scarce. Bottled fruits are also very useful on board vessels at sea, where fresh fruits are not procurable. It is consequently only in seaport towns or in winter and early spring that they sell well. Retailers should not overstock them, for, although they may keep in fair condition a long time when stored in cool dark cellars, they lose much in appearance by frequent removal and continued exposure to the light. At their best also they lack much of the flavour, and cannot compete in price with fresh gathered fruits. In preparing them, the fruit, especially the soft, is best when gathered, picked, and bottled the same day, and handled or crushed as little as possible. It should be gathered when dry, and should not be quite ripe. A sufficient quantity of spring water, to each gallon of which 4 ozs. sugar, or ½ oz. alum, or ¼ oz. of saccharin has been added, should first be boiled for a quarter of an hour, skimmed, and, when clear, turned out into a tub to cool. Few persons really know why the fruit must be quite dry when gathered if water is put to it in preserving, so we may explain that wet fruit detached from the plant *immediately* begins to decompose, and in six hours its flavour would be quite spoilt, whereas the water needed in cooking is at once heated, sterilised, and incorporated with the juice of the fruit. To resume, the bottles should be perfectly sound, clean, and dry, with

necks narrow or extra wide to suit the size of the fruits. Then pour a teacupful of cold water into each bottle to break the fall of the fruit, fill in the fruit—if gooseberries, top and tail them; if currants or cherries, pick off the stalks—and then fill the bottles up to the shoulder, knocking the bottle firmly from time to time on the table so as to shake the fruit well down, add more water to wash the fruit, then pour it off, and let them drain a short time upside down, and finally fill the bottle up with the liquor, leaving just enough room for the cork. Drive in good corks tightly with a "flogger," and tie each down firmly like a ginger-beer or champagne cork. Then stand the bottles upright in a suitable flat-bottomed bath, pan, or boiler, fill the vessel up to the lips of the bottles with cold water (but not so as to wet the corks), put a fire under and gradually bring them up by a thermometer to the heat—for green fruits, 180°F., and for red fruits, such as currants, cherries, raspberries, etc., 190° during a period of about two hours; then remove the fire, and leave the bottles in the water to cool gradually. The bottles may then be taken out of the water, and allowed to stand a few hours to dry. They are then finished, and may be gently stowed away on their sides in a dark cool cellar. When wanted for sale, they may be brought out and polished; the top of each bottle dipped in melted wax, or covered with tinfoil (like champagne bottles), labelled, and wrapped in paper.

Mr. Saddington might be named as the discoverer of the first method, and was awarded a premium by the Society of Arts in 1807.

A little alum being added to the water or syrup for the purpose of hardening the tender skin of the fruit.

A process not very unlike the above is that of M. Appert, who in 1810 obtained a reward of 12,000 francs offered by the French Government for the best method of preserving food. By Appert's improved method, the vessels are corked and wired throughout the whole process, the oxygen air in the vessel being destroyed by the heat.

Many of the larger manufacturers now employ steam sterilisers instead of the water baths, and sterilise the bottles before filling them.

Sometimes the fruits are preserved in glass jars with screw metal tops. These are filled in same way as bottles, but, instead of corking, the metal lids are screwed on loosely without the rubber, and when sufficiently boiled they are filled up with hot syrup, the necks are wiped, rubbers fitted on and screwed tightly down.

Another way is that commonly adopted by American housekeepers; it is simply to boil the fruit in sugared water in a procelain-lined stew-pan or kettle until it is sufficiently cooked, and to pour it boiling hot through a funnel into the jars, stirring it about with a spoon to let the air bubbles escape. The jars are then filled up with hot syrup, wiped with a moist towel, a rubber ring fixed, and then tightly screwed down. They are further tightened when cold. A little warm syrup is usually put into the jar before the hot fruit to temper the jar. One woman can thus preserve about 2 bushels of fruit per day.

Bottling and preserving fruits, jellies, pulps, juices, etc., is indeed a very simple matter now with the new and improved automatic bottles.

American fruit-houses preserve vast quantities of fruit by what is known as the "California Cold Process." The fresh fruit is just put into the vessels intended for it, and a solution of the compound extract of salyx is poured over it, and it will keep its natural colour and taste for years. A single person can thus preserve large quantities in a very short time, say a bushel in ten minutes.

Bouillabaise (*boo-yah-bess*).—A fish soup of Marseillaise origin, consisting of salt-water fish, onions, carrots, shalots, and oil; and seasoned with lemon-juice, saffron, cloves, thyme, parsley, pimento, pepper, cayenne, and salt.

Very popular about Marseilles, the southern French being, like Spaniards,

very fond of oil, shalots, and garlic with their food.

Readers may remember this medley has been very lovingly described by Thackeray.

Bouilli. — A French name for beef or other meat that has been boiled, especially the former, and in which are mixed vegetables, herbs, and other seasoning.

Bouillie Bordelaise. — A French liquid for sprinkling over vines and similar plants to prevent mildew.

It consists of 3lbs. of sulphate of copper (blue-stone) and 1lb. of slaked lime, boiled in 22 gallons of water; and is so named because it was first used in the Bordeaux vineyards. Another similar mixture is the "*Bouillie Bourguignonne*," used in Burgundy. Opinions vary as to whether these liquids render the wines somewhat poisonous, hence the grapes are only sprinkled while very young.

Bouillon. —A French name for the stock or liquor in which meat, bones, vegetables, herbs, spices, etc., have been boiled or simmered, and from which basis various soups or broths may be afterwards prepared. Clear stock is called *Consommé*.

Bouquet Garni.—A bunch of sweet nerbs. Thyme, marjoram, parsley, chives, and bay-leaf are the most usual combination.

Bourbon Coffee. — A highly esteemed variety of coffee from the French island of that name in the Indian Ocean.

The berries are of a pale, almost whitish, colour.

Bourbon and Martinique coffees go exclusively to France, but are often substituted by what is known in the trade as Bourbon or Mocha-seed, Santos, Jamaica, and other fine mild sorts.

Bourbon Tea.—See *Faham Tea.*

Bourguinote. —A sort of stew with truffles, generally made from game.

Bouza. — A fermented drink, prepared in Abyssinia and Arabia from teff, the seeds of *Poa Abyssinica*, and from the seeds of *sorghums* or *millets*.

Bovril. — Bovril was invented to realise Baron Liebig's desire for a meat food that would contain not only the stimulating properties of flesh—as all Meat Extracts and beef-teas do—but also the nourishing properties of flesh, which Meat Extracts and beef-teas do not. It is manifest that if a food can be presented with this desirable combination of the extractive and nutritive qualities of meat, it would be preferable to all others. Bovril, Limited, explain that this has been accomplished by first taking the extractive principles by the Liebig process (which is akin to home-made beef-tea) and then adding albumen and fibrin, procured from the flesh of *other beeves* roasted and finely ground to powder; the combination is Bovril. Lord Playfair and Sir Edward Frankland confirmed the scientific value of the invention, and Professor William R. Smith, President of the Royal Institute of Public Health and Medical Officer to the London School Board, endorses the soundness of the therapeutic value of the product.

Braden's Farinaceous Food.—Seems to be composed chiefly of wheat flour carefully baked.

Braise. — A French name for small (braised) coal. *Braised Beef* is an American preparation of pieces of meat, cooked, spiced, and put up in tins, often with rice, gumbo, etc.

Brambles or **Blackberries.** — F. *Mures de Ronce;* G. *Brombeeren;* W. *Mieren.*

The fruit of a very common, but one of the most variable, of British wild plants (*Rubus fruticosus*). There are upwards of twenty sub-species, all nearly related to the raspberry. The parsley-leafed variety, *R. laciniatus*, is perhaps the most useful; but the Warwickshire cultivated type, of purplish-black and shining colour, is a rich and well-flavoured fruit. The other common varieties are the red fruited (*R. f. suberectus*) and the hazel-leafed (*R. f. corylifolius*). The blue brambles

(*R. f. coesius*) are best known as *Dewberries*.

The bramble flowers and fruits late in summer, and the berries, antiscorbutic and very wholesome, although rather insipid, make a fairly nice jam, of delicate flavour, also a pleasant wine. It is surprising they are not more cultivated, for those that reach the market fetch as much as raspberries. Perhaps they are not tart enough to please the modern taste for acid fruits, and if more were marketed the price might decline. Sugar is cheap, and the demand seems to run upon sour fruits and plenty of sugar rather than the sweeter fruits with less sugar.

Bran.—F. *Son;* G. *Kleie;* Port. *Farelo;* Sp. *Salvados;* W. *Rhuchion.*

Bran contains a large amount of nitrogenous matter, and flour loses a very valuable portion of its nutritive power by separation of the bran. Uses:—(1) A handful of bran mixed with a pail of warm water makes an excellent foot-bath. (2) Infused in hot water and sweetened it forms bran-tea, a gentle laxative and very good for coughs and hoarseness. (3) Bran poultices. (4) Feed for horses, either mixed dry with their corn or made into bran mash. A bran mash made by mixing together half a pail of bran and half a pail of boiling water, and stirring in about ¼ oz. of ground saltpetre, forms an invaluable weekly corrective for a horse. It should be given lukewarm on a Saturday night, and half a pint of linseed boiled along with the water is a great improvement.

Brandreth's Pills.—A mild kind of purging pills, said, on the authority of two American druggists and one dealer, to consist of gamboge, podophyllin, the inspissated juice of pokeberries, saffron, turmeric, cloves, and peppermint oil.

Brandy.—Du. *Brandewyn;* F. *Eau de Vie;* Ger. *Brantwein;* It. *Aquazente;* Rus. *Wino;* Sp. *Aguardiente;* W. *Brandi.* (See also *Cognac* and *British Brandy.*)

The name brandy is derived from the old German word *Brantwein*, meaning burnt (distilled) wine. About 200 years ago it was also known as *Nantz*, from the town Nantes, the capital of the Loire Inferieure, whence it came; but this name was changed afterwards to "Cognac," where a large amount of brandy is still made.

This spirituous and inflammable liquor is indeed nearly all prepared in France, the chief distilleries being at Cognac, Bordeaux, Rochelle, Orleans, Nantes, and Languedoc. It is usually about half pure alcohol and half water. Cognac brandy is considered the best, and when genuine is understood to be obtained by the distillation of wine. Another variety, technically known as *Eau de Vie de Marc* or *Eau de Vie d'Aisne*, is distilled from the lees, skins, and refuse of grapes after wine-making, but it is somewhat coarse and unpleasant in flavour on account of an acrid oil in the grape skins.

In France brandy is also being made from apples. There was an enormous crop of apples in Normandy in 1895, and it was thought that the making of brandy might prove commercially possible. The yield was not great (five per cent.), but the quality, it is said, left nothing to be desired.

When fresh, distilled brandy is colourless, and will keep so in glass bottles, but may afterwards get colour from the casks. The colour is nowadays principally derived from the addition of burnt sugar or saunders-wood; but brown brandy is generally very inferior.

Great Britain seems to secure nearly all the best French brandy just as she has the choice of the finest French wines. The two principal and several of the subordinate firms at Cognac are of British origin, and, indeed, so predominant is the English element there that Frenchmen dub it the little English town.

A hundred years ago brandy was the favourite drink with the aristocracy, as was gin with the common people; but pale brandy was not then so much esteemed as brown. As a rule, the large firms in France do not themselves distil

the brandy they sell, but leave that operation to the small farmers round about, and then blend the various products, because to produce the quantity those firms sell, enormous distilling space would be necessary. The crude, white spirit from the farmer on arriving at the brandy factory is tasted, measured, and put into new oak casks, hooped round with chestnut wood, branded with date, quality, and place of growth, and stored till required for blending with other growths, filtered and kept for several years to mellow. The pleasant aroma is due to the presence of ethyls or developments of fusel oil, found in the marc or husk of the grape.

Beet-root spirit, produced from the refuse syrup in making beet sugar, is also often used extensively in brandy making; but a very large proportion of the brandy sold in this country is simply raw grain spirit flavoured and coloured. The spirit is exported from England and Germany into France, where it is re-distilled and converted into so-called French brandy.

Peach Brandy is a popular spirit in the United States obtained from the fermented fruit of the peach.

A great deal of the spurious brandy is made at La Rochelle, and, no doubt, the English dealers are as much to blame as the French merchants. The former know well enough that it takes 8 gallons of wine to make one of genuine brandy, and that the first cost of this latter is, therefore, about 7/-, and that it is not fit to use until kept for some years, so that the cost of storing, caring, and the loss of a certain part of it, interest on capital, and the profits of the dealer may fairly carry the price to 12/- per gallon. In buying brandy at 2/6 to 4/- a gallon, the British merchant must, therefore, know quite well it is not a genuine article, and, doubtless, much of it is made with "ethylic alcohol."

In Northern France genuine brandy is professedly the natural product of wine, cider, or other fruit juices, but over three-fourths of that is manufactured in the Northern departments from raw grain spirit or "*alcool d'industrie*," obtained from maize, rice, and other farinaceous substances, as well as from molasses and beetroot. This sort of spirit also passes as "Clear spirit," "Berlin spirit," etc. An appearance of age is commonly given to brandy and other alcohols by spraying the spirit into an atmosphere of oxygen. By a process of M. Villons, the spirit is heated to 70°C., and oxygen is then pumped in at a pressure of 5 to 6 atmospheres, care being taken to maintain the pressure for 12 hours, the liquid being agitated from time to time. By repeating the process two or three times, all traces of fusel oil are driven off and at a trifling cost.

For reasons above shown, French brandy is only used by those ignorant of recent practices, and is no longer recommended by the doctors. The valuable property in brandy is the alcoholic ether, which is developed by age only, and is entirely absent in the modern imitations.

Spanish brandy is now considered much superior to French, owing to the fact that wine in Spain is very cheap, and, therefore, more generally used for brandy-making.

The strength of brandy as sold varies from proof to 30 or 40 under proof, but by an Act of Parliament, 42 and 43 Victoria, c. 30, s. 6, all brandy below 25 under proof is considered adulterated, unless a special declaration be made as to its actual strength.

The best way to reduce brandy is to use distilled water; neither boiled nor filtered are so good, and well water turns it cloudy. If imported in casks, the casks must not be smaller than 20 gallons, and in ships of not less than 50 tons, or forfeited. The duty is 10/4 per gallon, and the annual imports average about 3,000,000 gallons.

Brandy or Cognac Bitters.—A compound bitter liquor, usually made by steeping bitter vegetables in weak brandy for a week or two, aromatic flavourings and sugar being also added, as with other bitters. Brandy bitters are also commonly prepared from a concentrated essence made and sold by the essence distillers at 6/- or 7/- per lb.

Some sorts known as *Wine Bitters* are made out of cheap white wines (cape or raisin).

Brandy-Snaps. — Thin wafer-like gingerbread biscuits, slightly flavoured with brandy, and generally curled in baking. They may be made thus:— 8lbs. of flour with 1lb. of lard or butter is formed into a strong paste; 6 ozs. of ground ginger, 6lbs. sugar, and 2lbs. of treacle are then added, also a little salt and either a little brandy or a few drops of essence of lemon to give flavour. The whole is afterwards well kneaded together on a well-floured board, rolled out very thin, and the snaps are then cut to shape with a tin paste cutter and baked in a slow oven. When about half baked and while pliable the curled shape is given by rolling them round pieces of wood and then baking them till crisp.

Brank.— See *Buckwheat*.

Branvin. —A species of gin largely consumed in Scandinavia, where its manufacture is a Government monopoly.

Brass Polish. — (See also *Metal Polishes*.)—Many of the brass polishes appear to be a mixture of tripoli and linseed oil—20 grains of the former to the ounce—a little rouge being added to bring up the colour. In the absence of tripoli, rottenstone and rouge are often used; but the regulation form seems to be 1 oz. oxalic acid, ½lb. soft soap, ½lb. sweet oil, 1 oz. oil of turpentine, 4½lbs. rottenstone, and 16 ozs. boiling water.

Dissolve the acid in the water, add the rottenstone, mix, and incorporate the other ingredients.

For materials apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Brawn, Collared Brawn, Mock Brawn.—F. *Tête de sanglier*; G. *Schweinkopf*: Port. *Cabeza de Cachaço*; Sp. *Cabeza de Jabali*; W. *Brôn*.

For centuries brawn has been an English national dish for Christmas-tide. They are of three classes (1) in moulds, (2) in skins, and (3) the old-fashioned close packed brawn.

It is professedly made from pig's or "wild boar's" head; but is now generally made from the head and belly piece, feet, and rind, of either the pig or the ox. The leg with ham rinds, or the neck, crop, chuck, with the spare ribs, gristle bones, and feet are all used, whilst, on a pinch, cows' heels, lambs' tongues have to form *mock brawns* in lieu of boar's head. Lean beef is sometimes added, and in low-priced qualities objectionable offal. These ingredients, salted or pickled, are boiled in water till quite tender, the bones are then removed and the meat chopped in a machine and well seasoned while hot with a mixture of salt, ground pepper, allspice, ginger, cloves, and a little cayenne. It is then left under pressure till firmly set. In summer a little gelatine is usually dissolved and well stirred in to help the setting—say ½ oz. gelatine for each pound of meat.

Most manufacturers add a little red colouring (vegetable) and borax or other antiseptic to improve the appearance, and keep it longer.

A considerable quantity of manufactured brawn has lately been coming from the United States, but it does not seem right that this should either come labelled or be afterwards labelled in large letters "English Brawn."

Special Firms.—Hillier's Bacon Curing Co., Ltd., Newmarket, near Stroud; Tebbutt & Co., The Works, Melton Mowbray.

Brazil Nuts or "Shoe" Nuts.— Du. *Brezille* or *Foelie Nooten*; F. *Noix Péchurins*; G. *Pechwunnüsse*; It. *Fava Bucari*; Port. *Pucharins*; Sp. *Becuiba*. (Also known as *Castanhas*.)

The fruit of the *Juvia Bertholletia excelsa*, a kind of myrtle tree, of enormous size, growing about 100 feet high in the vast forests of Guiana and Venezuela, as well as in the north-west of Brazil, and particularly on the banks of the Orinoco river. These triangular-shaped nuts, so familiar in our shops, grow in a thick, hard, round, woody outer shell or seed-case, 4 to 6 inches in diameter, not much unlike the milky cokernut.

In this outer shell, seed, or pericarp are four or six divisions, with 20 to 30 of the well-known three-cornered nuts, packed closely together, each of these latter also having a hard brown shell of its own.

A striking instance of the fierce and fatal competition which goes on even amongst plants is found in the case of these small nuts, for although the whole of them germinate at one time, it is only the most vigorous one which gets first through a small hole at the top of the large outer shell to the open air, and thereupon it fills up the hole and strangles the rest and feeds upon them.

The almond-shaped inner kernel of the nut, when peeled of its dark skin, is white, and if fresh is sweetish and possesses a very agreeable flavour, very like that of the hazel nut.

About 300 years ago they went by the name of *Peru Almonds*.

The kernels contain about 56 per cent. of oil, and, consequently, will not keep very long, but turn rancid, and are then almost useless, although from the close-fitting shell they possess they will keep better and longer than walnuts.

The oil extracted from Brazil nuts is of a bland character and is much used by watchmakers, also sometimes for burning in lamps.

To procure the nuts from the lofty trees, the Indians generally commence by pelting the monkeys with stones, and the monkeys reply by hurling down at their heads the large hard cases full of these three-sided nuts. The cases are usually broken open with an axe or hammer, and the nuts then taken out. It is very dangerous to enter the forests when these nuts are ripe without protecting the head and shoulders with a wooden covering, the hard wooden seed-cases being heavy enough in falling to break a man's skull. In the great Amazon valley the gathering of these nuts is quite a business, the total exportation being about eight million hectolitres yearly. The larger nuts are from the Manaos region and the smaller from Para. A bag of Brazil nuts (at barrel measure) weighs about 1½ cwt. New crop usually begins to arrive early in March. From Para and French Guiana they are mostly exported in baskets or "alquieres," of 60 to 80lbs. each.

Brazilian Arrowroot is a commercial name for the starchy powder of the ground mandioc root after its separation from the fibre.

Brazilian Cocoa. — See *Guarana*.

Brazilian Coffees. — The annual exports of coffee from Brazil exceed 400,000 tons in weight and £20,000,000 in value. It is estimated that about three-fifths of the coffee used in the world is raised in that country, and the bulk of what reaches England certainly comes from there; Rio, Venezuela, and New Grenada are the chief coffee-growing districts.

Some Brazilian coffees have, however, a peculiar almost unclean flavour, and are used for mixing with other kinds.

The newer variety called *Maragogipe*, from the province of that name, is coming much into favour with planters. The flavour is inferior, but the berries are larger than ordinary varieties—not, however, so large as Liberian—but being a good and early cropper, it serves to cheapen *genuine* coffees.

In Brazil the plants are raised in seed-beds and transplanted at one year old in the plantation in the *quincunx* order, with about four hundred plants to the acre. Holes are dug for the plants, ploughing being impracticable owing to the stumps and roots left in the ground to decay; the hoe and mattock do the subsequent work, which is to keep down the weeds.

In four years the plants begin to produce, the trees grow about ten feet high with a diameter of about five feet, and keep in bearing for forty years with careful pruning. There are three annual bloomings and crops.

"*Maragogipe*" plants, however, grow much more rapidly, and yield fruit in the third year.

The coffee is gathered in baskets and carried to yards of hard beaten clay, where it is dried in the sun or in drying pans by artificial heat. The outer shell

is separated from the beans by machinery, and the thin inner husk by still other machinery, and the coffee is then ready for market.

Its quality is much improved with age; the aroma increasing as desiccation goes on. The best Brazilian coffee is, when dried, of a pale yellow; while the new immature beans are green.

The different varieties possess different qualities, though from the same crop are obtained so-called Mocha, Java, and others that figure in our markets. They are simply different sizes of beans separated by machinery.

For those who do not know that a green colour is a sign of immaturity the light and spotted beans are dyed to a beautiful green, which is easily washed off, as indeed it should be before using. There is very little true Mocha imported; but the tubular shaped berries found growing singly in the pod, and called "virgin," "male," or *pea-berry*, are found mingled with all crops and are easily separated from the larger and flatter beans, growing two in a pod, closely resemble, and are, in fact, often sold as Mocha. True Mocha has about 510 beans to the decalitre.

Brazilian Tea.—Obtained in Brazil from the plant *Stachytarpheta jamaicensis*, a kind of Verbena.

Bread.—Da. and Sw. *Bröd;* Du. *Brood;* F. *Pain;* Ger. *Brod;* Port. *Pao;* Sp. *Pan;* Sax. *Breod;* W. *Bara.*

The conventional names and forms of bread are very numerous. There are the 2lb. and 4lb., 8lb. and 12lb. loaves, square and round, the round being called "cottage" in some districts. Then there are "pan" or tin loaves, "sandwich," square and round, from 1½ to 14lbs. each; French and Vienna twists and crescent-shaped loaves, Coburg loaves, cobs, and cottages; the *heart loaves* of Edinburgh called "French"; Melvins, crusty and crumply loaves, tin cakes, Hungarian loaves, Cauliflowers, etc.

French Bread, Germ Bread, Milk Bread, and Whole Meal Bread are mentioned elsewhere under their respective headings.

The ordinary baker's way of making bread is first to prepare the "ferment," which is usually done from eleven to twelve o'clock in the day. It takes about ten minutes to do it. Potatoes—in the proportion of 1½lbs. to the bushel of flour, or 9lbs. to the sack of 280lbs.—are first boiled and then mashed in a tub. Two quarts of hot water are added, and the mash is well stirred. When the mixture of water and of potatoes is complete, cold water is added, until the whole is cooled down to 80°F. After this, yeast—1 quart of brewer's yeast is the usual quantity—is mixed up with the mash in the tub, and about 2lbs. of flour are added to "feed the yeast," and the whole covered over and allowed to stand from six to seven hours. If what is called "patent yeast" is used, the water that is added to the mash is left at from 90° to 100°F. instead of 80°. The mixture is called *the ferment*. It ferments to a "head," and then falls once, and sometimes twice. It is ready for use when the fermentation has ceased. At about five or six in the evening the "ferment" is ready to be mixed with one-fourth part of the flour which is to be made into the bread. This is commonly called "setting the sponge." The admixture is usually made with the arms of the workman, water being added in sufficient quantity, from seven to eight gallons to make "the sponge." The "sponge" remains from five or six in the evening until about midnight, in order to undergo the process of fermentation. It rises the first time in about four hours, then it falls. It rises a second time in about three-quarters of an hour to an hour afterwards. So soon as the sponge is ready, the remaining three-fourths of the flour which is to be made into bread is added, and the workman proceeds to mix the added flour with the sponge, with more water, and with about 3lbs. of common salt. The water now added is about 8 gallons, the whole quantity of water required for every stage of the process of making bread from the finest flour

being about 16 gallons to the sack of 280lbs.

Making the dough, or kneading, now begins, and this is the hardest work which the baker has to do. It takes a man about three-quarters of an hour to make a sack of flour into dough. After the dough is made it stands, according to the kind of yeast used, or whether the weather be hot or cold, from half an hour to 2 hours; shorter if the yeast used be of best quality. and the weather be warm, and *vice versâ*. During this interval, the baker takes some refreshment and has a rest. About two in the morning he proceeds to weigh off the pieces of dough, which are put aside as they are weighed. When all the dough is weighed off, the process of moulding the loaves commences. A 280lb. sack of flour may yield 90 to 95 loaves of 4lbs. each, and they are put into the oven as fast as they are moulded. The boards on which the bread is weighed and moulded are scraped and brushed every time they are used, and many masters have them washed once a week; but the moisture left from washing has a tendency, in the opinion of some masters, to make the bread sour.

From two to three in the morning until five the bread remains in the oven, where it is exposed to a temperature of 400°. There it passes through the process of complete cooking, with the formation of crust. The bread is withdrawn, and when cool enough is ready for sale.

Every person selling household bread (not "Fancy" or "French" bread) is bound to sell by *weight*, and on being asked for a two-penny or other priced loaf the seller is finable unless he weighs it; but although it is a custom to sell it in 2lb., 4lb., or 8lb. loaves, there is no legal compulsion to adopt these weights. To obtain loaves of 4lbs., a baker usually weighs 4lbs. 6 ozs. of dough. The weight of bread obtainable from a sack of flour depends chiefly on the water added and the amount of gluten in the flour, the difference arising from the large amount of moisture retained in the latter, hence light, spongy, fermented bread is cheapest for the consumer. The loaves nearest the fire lose most in weight, and tin loaves more than *oven bottoms*. Mrs. Rundell says 14lbs. of American flour will make 21½lbs. of bread, whereas the best English produces only 18½lbs. This is said to arise from the superior quality of American wheat, and also from its being kiln-dried before grinding.

The degree of hydration of bread also depends much on the shape of the loaves, and for equal weights a long one is preferable to one of a round form. Ever since the introduction of rollers for grinding wheat into flour, the want of moisture in bread has been a source of complaint, and this is explained as follows: It is said that the baking quality of flour depends chiefly on the oil contained in the germs of the grain; that in roller-ground flour these germs, and along with them the oily matter, are separated from the flour, and that such flour, although lighter in colour, is dry and husky, while in stone-ground flour they are retained. Hence the better taste and softness of bread made of the latter, which, nevertheless, has one defect, the oil is very oxidisable, causing the flour to turn sour in a shorter time. Roller flour is undoubtedly whiter than stone-milled flour, but the latter is certainly the best. Unfortunately, the public are led by colour, and of course the customer is the master.

Recent experiments, however, have proved that a little almond oil mixed with the dough made of roller flour, one part by weight of oil to 500 of flour, produces a bread not only just as savoury and elastic as the stone-flour bread, but even superior to it. On the other hand, bread made of the same kind of flour without the almond oil has proved tasteless and died out very soon.

The fermentation of bread seems to consist in a normal alcoholic fermentation of the sugar which already exists in the flour.

The yeast plays a double part in the process—it produces a disengagement of gas, which causes the dough to swell, and it prevents the bacteria, which are

parasitic on the starch grains, from developing and thus making the dough sour and dissolving the gluten.

On adding the yeast a fermentation ensues, and there is a continual evolution of gas which accumulates in the bakehouse, the starch changes into sugar, and the sugar is decomposed into carbon dioxide, and alcohol.

The gluten prevents or retards the escape of the carbon dioxide, and the tension of the warm gas expands the little cells which give bread its spongy appearance, but the alcohol escapes, and must affect the bakers.

Sour bread is generally caused by poor yeast, especially during the warm months. The acidity of the yeast is imparted to the bread, and too much acidity produces sour bread. All yeast should be carefully tested before use. Unsound, or sprouted wheat will also cause sour and runny bread. If flour is left in a damp place or package it will become tainted and make sour bread.

If both flour and yeast are sound and good and the bread made therefrom is sour, it is due to leaving the dough too long over some stage of working, or, as it is generally called, overfermentation. It is a fact that the alcoholic fermentation of dough, by which normal aeration is caused, is followed by fermentation which results in sourness. Again, changes in temperature or the degree of stiffness of the dough may accelerate or retard fermentation as a whole, but they do not alter its character and general course. Thus we can see that there are many things aside from poor flour that may cause poor baking results.

Good, strong flour, sound yeast and a good baker will, as a rule, make good bread, but under the head of good baker there are many points to be considered: First, careful attention to the temperature of the water, oven, and the flour itself. Second, proper kneading of the dough—do not knead it too stiff. Third, slack dough will ferment quicker than stiff dough, therefore, it must be handled quicker. All of this comes to the baker and housewife by experience. More bread is spoiled by poor and careless bakers than by poor flour.

Spring wheat flour will make more bread to the barrel than winter wheat flour, as a rule, because of its having 3 to 5 per cent. more gluten, consequently it has more expansion, and as it is milled more granular it will absorb more water. The most palatable and satisfactory bread-making flour is that which gives the best flavour, retains moisture the longest, and is free from branny or germy particles and at the same time has a good colour.

Winter wheat patent will fill more of these requirements than spring wheat. Of course, the professional baker prefers the strong flour—the one having the greatest water absorbing quality—as his profits increase accordingly. But for all-round family use and general satisfaction, especially as to colour and moisture of loaf, the winter wheat flours have the preference and generally sell for more money.

A blended flour of one-third spring and two-thirds winter is quite popular and a good one to use. It is almost universally used by large bakers. It gives both colour and strength, and retains the other qualities better than if either flour was used alone.

Alum.—Opinions of both chemists and doctors differ as to whether the moderate use of alum, say 5 to 10 grains to 1lb. of bread, is really injurious, but there is no doubt the bread produced is both whiter and finer if alum be present; it is said that even second quality flour with alum will make nicer-looking bread than *first* flour without it. Both millers and bakers frequently add it to bad or slightly damaged flour.

The whitening effect seems to be produced by the alum preventing the *cerealin* re-acting on the starch present in the flour from generating sugar and dextrine, which would cause a darkening in colour.

But there is that other *weighty* reason for its use, it enables the flour to absorb a larger quantity of *water*, and so produces a greater weight of bread from a given weight of flour.

Alum in bread is easily detected. The materials necessary are a solution or tincture of logwood, to which a sufficient quantity of carbonate of ammonia has been added to render it strongly alkaline, and some slips of gelatine; a slice of the bread is then crumbled into a glass and covered with pure water, a slip of the gelatine is added, and the whole allowed to stand over night. In the morning the swollen and softened slip of gelatine is removed and stained with the ammoniacal logwood; if no alum is present the gelatine will be of a dark pink or red colour, but if the bread contain alum the gelatine will be coloured various shades of blue, from a barely perceptible purple up to quite a decided blue, according to the quantity of alum present.

A rough and ready test is to dip a slice of the bread into a watery solution of logwood, when the claret colour may be produced at once; but perhaps the most convenient way of applying the logwood test is to macerate 4½ ozs. of logwood chips in 8 ozs. of spirit for 24 hours, and filter. A few drops of this added to moistened bread or bread-crumb or flour in a little water will readily show up a lavender or blue colour if alum be present.

In searching for alum, the crust and the crumb should be analysed separately; for many bakers use for the latter a flour technically called "cones," which is strongly alumed, and prepared from a fine species of wheat grown in the south of Europe, mixed with rice. This mixture is used for dusting the kneading trough and kneading boards, in fact, for facing the sponge before baking it.

Lime, sulphate of zinc, and copper sulphate have also been used, the latter, however, more generally on the Continent. Lime, however, presents a marked advantage, that of preventing the *souring* of bread by retarding the fermentation of the starch into lactic acid. Potatoes and damaged rice are often used by some bakers, and there are cases where gypsum, chalk, and pipe-clay have been used. The mixture of potatoes and boiled rice is added to enable the flour to take up more water, so that five or six additional loaves may be sometimes made from a sack of flour. The pipe-clay or Paris white being insoluble, will be noticed to settle at the bottom of a vessel filled with water and a little of the crumbled bread or flour.

Rice, potatoes, pea-flour, etc., are best detected under the microscope by the form of the granules.

The causes of holes in bread are said to arise from (1) the excessive use of low-priced Indian wheat in producing cheap flours; (2) weak yeast; (3) insufficient kneading of the dough; (4) bad moulding.

The black or purple mark often seen between the head and bottom of a loaf is due to too much fermentation, and generally betrays *sour bread;* while the hard streak extending from side to side is often caused either by a knock or fall such as to cause a concussion between the head and bottom, especially before the batch is sufficiently baked; or it may also occur by reason of the head before baking being removed and replaced in such a manner as to leave a skin on the inside.

Fresh and Stale Bread.—A 4lb. loaf loses about 1¼ oz. in 24 hours, about 5 oz. in 48 hours, and about 7 oz. in 60 hours, but this loss varies a little with the temperature, draughts of air, etc.

For Best White Bread (according to Mr. Wells).—Take 8lbs. of flour (say Hungarian best brand), 3 quarts of milk and water in equal proportions, 3½ ozs. compressed yeast, and 1½ ozs. salt. Mix the water (warm) with the milk so that the final temperature may be about 85°F., dissolve the yeast in this, and with a little of the flour make a flour ferment which should stand for about one hour; then add the remainder of the flour and the salt and thoroughly knead all together. Let this lie for 2½ hours, then work off, prove and bake. If a jet of steam can be introduced into the oven the bread will get nicely glazed. During many years the women folk of England have preferred the whitest flour, which taste the roller millers

hastened to supply, but nature is stronger than fashion, and the human stomach has craved for something to fill the gap caused by the removal of all the colouring matter, hence we see "*Germ*," "*Hovis*," "*Vagos*," and other specially prepared compounds, wholemeals, etc. To bring up children exclusively on fine white wheaten bread is both cruel and foolish, and is greatly the cause of the enfeebled frames of a large proportion of our towns' populations. Indeed, the numerous patent meals, breads, etc., adapted for weak stomachs, also appear to suggest that many persons are finding out that ordinary white bread is by no means the "staff of life" it has long been supposed to be.

When bread was formerly rated according to the price of wheat, the decree setting forth the price was called *Assize*, hence the name "Court of Assize."

As already shown, the law requires that all bread, except "fancy bread," should be sold by weight. The bread must be weighed after being baked, and in the presence of the purchaser if required. The Act of Parliament also provides that all bakers and sellers of bread, who send bread out in carts, must carry with them constantly in such carts correct and proper weights and scales, and must weigh such bread when requested in the presence of the purchaser, or in default pay a fine not exceeding £5.

"Fancy bread" must differ from ordinary bread in make-up or in being marked.

The weekly consumption of bread in pounds per inhabitant is in Germany, 11·2; France, 9·7; Russia, 9·4; United States, 7·5; Great Britain, 6·3; Austria, 6·0; general average, 8·5.

Bread and Flour Weights.—A peck loaf weighs 17lbs. 6½ ozs.; a half peck loaf, 8lbs. 11 ozs.; a quartern loaf, 4lbs. 5½ ozs.; a peck, or stone of flour, 14lbs.; a bushel of flour, 56lbs. 6 oz. a pack of flour, 240lbs.; a sack, 280lbs.; a barrel of American, 196lbs. A rise or fall of 4/- per sack of flour means a difference of ½d. per 4lb. loaf.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating flour and meal. Catalogues free.

Bread-Fruit.—The fruit of the *Artocarpus incisa*, or bread-fruit tree, a native of the South Sea Islands, but now flourishing in several of the West India Islands. It is not unlike a large apple tree, growing 40 to 50 feet high, but with a soft herbaceous stem, and often rises half that height without a branch. Yields fruit in three years from planting the seed, and bears dark green glossy leaves 12 or 18 inches long, large, rough and lobed, and the spherical shaped fruit hang on the boughs not unlike large pine-apples, sometimes in clusters of two or three. They are rough-skinned, knotty, and about the size of a large turnip, say 5 to 8 inches in diameter, and some 3 or 4lbs. in weight. The bread-fruit is at first green; when half-ripe, brown, and at this stage it is best appreciated by experts; when fully ripe it is yellow and juicy, but with a decayed or rotten taste. It is usually gathered green in October or November, when its pulp is white and mealy, with little taste, and not unlike the crumb of a wheaten loaf. Though insipid, it is highly nutritious, and in Tahiti and Samoa forms a most important food to the natives, bearing two or three crops a year, and, in fact, during the eight or nine months while bread-fruit is in season they use no other bread.

The bread-fruit of Otaheite is the most valuable of this species. It ripens during eight months of the year, and the prepared fruit, slightly dried, supports the natives during the remainder. The fruit is baked entire in hot embers, and the inside is scooped out.

Bread-fruit is cooked in various ways; roasted in thick slices it tastes like frosted potato; sometimes it is boiled or fried in palm oil. When baked it will keep for some weeks, but uncooked not more than twenty-four hours. The natives of several of the Pacific Islands use the wood for boat-building, and a sort of cloth is made of the inner bark;

the flowers serve as tinder, the leaves for wrapping up food and as towels, and the juice as cement for filling up cracks in water vessels and as bird-lime. Its fruitfulness is said to exceed even the generous plantain or banana. It dispenses entirely with the labour of the agriculturist, the miller, and the baker. There is no care for seed time or harvest, no thrashing, no grinding, no kneading —in fact, the islanders have their bread as it were ready prepared, and have only to place it on the fire as they need it. In fact, a Polynesian owning twenty ordinary bread-fruit trees is independent for life, unless his enemy wantonly destroys them. Other species of this tree yield the *Paw-paw* and the *Custard Apple*.

Breadstuffs.—An American term for the various kinds of grain, meal, or flour from which bread is made.

This in most countries is wheat or rye, but in other countries maize, millet, and other cereals are used. There are some civilised nations a large proportion of whose peasantry eat little or no bread. Baked loaves of bread are unknown in many parts of South Austria and Italy and throughout the agricultural districts of Roumania. In the villages of the Oberstiermark, not very many miles from Vienna, bread is never seen, the staple food of the people being *Sterz*, a kind of porridge made from ground beech-nuts, which is taken at breakfast with fresh or curdled milk, at dinner with broth or fried lard, and with milk again for supper. This *sterz* is also known as *heiden*, and takes the place of bread, not only in the Stiermark, but in Carynthia and in many parts of the Tyrol. *Pumpernickel* is the chief food of the Westphalian peasantry; and *Mealies* are the staff of life in Africa. In the north of Italy the peasantry live chiefly on polenta, a porridge made of boiled maize. The polenta, however, is not allowed to granulate like Scotch porridge, or like the Austrian sterz, but is boiled into a solid pudding, which is cut up and portioned out with a string. It is eaten cold as often as it is hot, and is in every sense the Italian peasant's daily bread. The modern Roumanians are held by many scholars to be descended from a Roman colony, in other words to be the cousins of the Italians; and, curiously enough, a variation of the polenta, called *mamaliga*, is the national dish of Roumania. Mamaliga is like polenta in that it is made of boiled maize, but it is unlike the latter in one important respect, as the grains are not allowed to settle into a solid mass, but are kept distinct, after the fashion of oatmeal porridge.

Breakfast Cereals comprise granular foods partially cooked or roasted:—*Cooked Crushed Oats*, *Rolled Oats*, *Cooked White Wheat*, *Cerealine Flakes*, *Avena Flakes* or *Prepared Oats*, *Hominy*, *Sowans*, *Succan*, *Groats*, etc. (See also *Prepared Foods*.)

Cereals are incomparably the most important of all the plants available for human food, and what is very remarkable is the great weight of the seed they bear in proportion to the total weight of the plants themselves.

Being often highly roasted or cooked, prepared cereals are much more easily digested by invalids, delicate children, and aged persons.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Breast Tea or **Pectoral Tea.**—An infusion composed of 8 parts of althea, 4 parts of coltsfoot leaves, 3 parts of Russian glycyrrhiza, 2 parts of anise, and 1 part of orris.

Brewers' Grains, Draff, etc.—The refuse of malt which has been used in brewing or distilling is called *grains*, and when fresh and sweet is chiefly fed to horses and cattle. The lees, dregs, wash, or swill is called *draff*, and usually served to swine.

Brick-bat Cheese.—So-called from its form; made chiefly in Wiltshire, from a mixture of new milk and cream, turned with rennet. The curd being put into a wooden vessel or mould, the shape of a

brick, is then pressed and dried in the ordinary way.

Brick-dust.—See *Bath Bricks.*

Brick Tea.—(See also *Teas, Chinese Tea, Caravan Tea*, etc.)

Brick Tea is one form of compressed tea. There are several others, such as Log Tea, Tablet Tea, Tile Tea, etc., taking their names from the various shapes into which they are pressed. It is said that more tea is sent from China in these forms than in any other.

They are packed thus in both China and Japan, to render them less bulky and more portable and convenient for transport over the long and mountainous regions between these countries and Russia, Siberia, etc. Brick Tea is, however, mostly manufactured and packed in Foochow and Hankow, where there are several factories belonging to Russian firms. The cheaper qualities of tea leaves, clippings from the tea-bushes, including stems, twigs, and broken leaves, also old teas left over from previous years, are all reduced to powder and mixed together. The quantity necessary to make a *brick* is placed in a cotton bag and softened by steam; the moist dust is then poured into a wooden mould, covered with a light layer of dry tea-powder of better quality, and pressed either by steam machinery or by blows from a heavy mallet until of the required consistency. It usually comes out of the press in hard solid rectangular blocks, but these bricks are of various degrees of compression; some kinds are only lightly squeezed into a loose mass. They are then carefully dried for about a fortnight without access of the sun or any other direct source of heat. Those lightly pressed are usually wrapped in paper and sewed up in cow-hide bags; while the more compact and resonant cakes are ornamented with gilt characters impressed on their surface without the least trace of leaf structure, and it requires an axe or hammer to break them.

The first cost of the tea-dust is about 1½d. per lb., and that of manufacture, export duty, packing, etc., about doubles the price, so that the total cost of the lower qualities of brick tea is only about 3d.

A large quantity is taken from China to Kiachta, where it is sold to the Armenians, Tartars, as well as to the Thibetans and Mongolians, who distribute it through the Russian provinces of Eastern Siberia.

The Tungou, Kalmuk, Khirghi, and Buratria natives use immense quantities of it. In Mongolia, where the pastoral population of herdsmen have little use for money, their tents, clothing, food, and temples being supplied by their flocks, Brick, or rather *Tile tea*, forms a standard of value and a convenient medium of exchange or barter, as it is in universal demand as food. After exhausting the compound with hot water in the ordinary way, these poor people regularly chop it up, and boil it either with mutton fat, butter, or *koumiss*, and the food is consumed hot in a liquid condition.

In fact, tea forms the staple food of Thibet; it is often prepared by churning the boiled tea with salt, soda, and butter; this mixed with a little barley flour is made into a sort of paste something like oatcake.

The people always add a little carbonate of soda to the water used in brewing their tea from chunks of these bricks.

Although much brick and tile tea is undoubtedly made up of inferior materials, and a little rice water often added to combine the brick and make it retain its form, yet the stories about blood and other substances being frequently mixed with the tea-dust are probably exaggerated. The absence of scent and flavour is owing to the steaming to which it has been subjected.

There are also *large green bricks* of the coarser sorts of tea-leaves (not dust) as well as small green bricks made of a better kind of tea, but both these are much sought after by the nomad tribes of China and Central Asia. The larger green bricks, in size 13 by 6½ by 1½ inches, weigh about 2½lbs. each, thirty-six large or seventy-two small going to

the "basket" when for export. The *small green*, 8½ by 5¼ by 1⅞ inches, are of finer quality, and bring a higher price. The third quality, *small black*, are of same size, and it is mostly these small *black bricks* made from tea-dust which go into Siberia.

Bride or Wedding Cakes. — F. *Gateaux de noce;* Port. *Pasteis de boda;* Sp. *Pasteles de boda;* W. *Teisen briodas.*

Grocers might do more trade in these as well as birthday-cakes, by first making themselves acquainted with the qualities, styles, and prices of the best makers, and then taking orders from families.

Most of the leading biscuit manufacturers employ first-rate artists in icing and decorating them, and keep up a stock from which to supply the trade on the shortest notice. The selection of a cake for the "happy event" is very properly a matter demanding much thought in feminine coteries. The weight, style and price per lb., with extra cost for ornaments, are all important matters.

A prettily ornamented cake of 10lbs. may be had for about a guinea.

Some firms have elaborate sketches or photographs of vases and ornaments which they send out for parties to select patterns preferred.

Brie Cheese. — F. *Fromage de Brie.*

A soft, salted, white cream cheese, made in the ancient province of Brie, in France, from pure cow's milk. Component parts:—Water, 34; nitrogen, 5·1; fat, 53·3; various, 7·6.

Fromage de Brie keeps well in the original boxes. If they should get soft, will harden on being exposed to the air by removing the cover from the box and putting them in a cool place. If too hard, can be made soft by putting them under a glass cover. If the wrappers become soiled or moulded, it is well to rewrap them in fresh paper.

Brillantine. — There are several of these preparations for polishing metals, glass, &c.

(1) Say one part of castor oil mixed with 4 parts of eau de cologne.

(2) 1 oz. of honey, ½ oz. of glycerine, and ½ oz. of eau de cologne, mixed with 2 ozs. of spirits of wine.

(3) 1 part glycerine, 3 parts castor oil, mixed with 60 parts of rectified spirit.

Brimstone.—See *Sulphur.*

Brine (for Pickling Meat).—F. *Saumure;* W. *Heli.*

This is made of salt and water, say 2lbs. of common salt boiled in a gallon of water, or 3lbs. of salt dissolved in a gallon of cold water. The above is best adapted for *vegetables;* if for pickling *meat*, use bay salt, and add 1 oz. black pepper, 1 oz. of saltpetre, and 12 ozs. brown sugar to each pound of salt, and boil for 20 minutes.

Best made from 3lbs. each of bay salt and common salt, with 1lb. brown sugar and ½lb. saltpetre, to each gallon of water. Boil and skim, and when cool it will be ready for use.

For some purposes a pound or two of bruised pimento or black pepper is an improvement.

Bringen or Liptau Cheese. — A Continental kind made in Hungary. Constituents:—Water, 34 per cent.; fatty matter, 28; Caseine, 23; salts, 5.

Brinjal. — See *Egg Plant.*

Brioches and Brioche Paste.—F. *Brioche;* G. *Apostelkuchen.*

Brioche paste is a species of paste or crust prepared from eggs and fine flour, fermented with yeast, to which are added a pinch of salt, a large quantity of sugar, and the whole worked in about half as much of butter as there is of flour. Besides Brioche halfpenny-loaves for shop sale, it is often used with soup, and as a casing for lobsters, patties, eggs, etc.

Briquettes.—There are three or four kinds of this fuel now manufactured from coal-dust, slack, saw-dust, etc., with a binding ingredient, such as tar, pitch, or clay, and pressed into blocks. The chief is made from coal-dust, others are made from petroleum, and in Victoria they are made from the lignite

fields of that colony. These latter yield about 44 per cent. of volatile matter, 31 of fixed carbon, 10 of ash, and 14 of water. Another kind is now being made at Gloucester, in which slack is the foundation, but so amalgamated with chemicals that the sulphur is eliminated, smoke abolished, and the heating power thus economically intensified.

The *Moniteur Officiel du Commerce* for August 2nd, 1894, gives the following as the formula of Signor Maestracci, of the Italian Navy, for obtaining briquettes of petroleum.

With a litre of petroleum there is mixed 150 grammes of triturated soap, 10 per cent. of resin, and 333 grammes of caustic soda. This mixture is heated, care being taken to stir it; when solidification begins, at the end of about forty minutes, observation is made as to the progress of the operation. If the mixture shows a tendency to overflow, some drops of soda are placed on the receptacle. The stirring is then continued until the solidification is complete.

The material is poured out into moulds so as to form the briquettes, which are then placed from ten to fifteen minutes in a stove. They are finally cooled, and can be used a few hours afterwards.

To the three elements constituting the above mixture Signor Maestracci recommends further the addition of 20 per cent. of wood shavings and 20 per cent. of clay or sand, which makes them firmer and more lasting.

An equal weight of these briquettes supplies about three times the heat of ordinary coal briquettes, and there is no waste.

In the process for making petroleum briquettes, described in "*Kuhlow's*," petroleum refuse is worked up in such a manner as to assume the form of a solid substance, easily handled, and constituting a cheap and convenient fuel. About 10 per cent. of soda lye, with about 10 per cent. of any fatty matter—tallow, for instance, is heated in a boiler, either by superheated steam or with exclusion of air; and so much petroleum refuse is then added to the heated mass as to make up one hundred parts. The whole is heated, with constant stirring, for about an hour, the time varying with the mode and intensity of heating; but the temperature must never be allowed to reach the boiling-point of petroleum, because in that case a large quantity of froth would form. In this incipient state of saponification the mass acquires the property of taking up large quantities of very fluid rock oil, and if this incorporation of the mass should proceed too slowly or remain incomplete it may be hastened by the addition of a little soda lye. In a short time the saponification of the grease with the fixing of the petroleum will be effected, and the mass thus produced may be run into moulds and allowed to cool, when it may be cut into pieces of any desired form. According to the use for which the briquettes are destined, they can during manufacture receive the addition of coal-dust, sawdust, and other refuse, and, if it be desired to obtain a product of less firm consistency, the grease may be entirely or partially replaced by resin or resin acid, the product in either case containing more than 80 per cent. of petroleum, more than 90 per cent. of combustible substances, and less than 5 per cent. of incombustible residue.

Briquettes from petroleum residues are also made by M. Louis Ghilini and Madame H. Sauvayre. The inventors prefer to use residues of naphtha, which they saponify by means of a caustic lye of 20° B. The naphthas are known as astakli. When the saponification is finished the product is mixed with resin and the whole is heated, well stirred, and poured into appropriate moulds. The proportions employed are as follow:—Astakli, 50 kilos.; lye, 15 kilos.; rosin, 8 kilos.

Turf Briquettes.—In Pomerania there is a factory at Langenburg where briquettes are made from moor turf by patent machinery. The fresh turf is first thrown into a machine resembling a turnip cutter and broken into small lumps. Then it passes to a second breaker, and is ground into mull or fine powder. Next it goes into a drier, or

steam cylinder, which is filled with exhaust steam from the engine, and is perforated by tubes much in the manner of boiler tubes, but larger. This cylinder revolves, and, being on a gentle slope, the mull passes slowly through the tubes, and by this means becomes thoroughly dry. From the drier it passes to a hopper, which feeds the "plunger." This plunger is worked by a 75-horse-power engine, and, by pressing the mull in a form against the preceding briquette, pushes them forward, each stroke the width of a briquette.

The factory turns out 80 briquettes a minute, or 35 tons a day, at a cost of about 7/- per ton for material and labour. The briquettes are retailed at about 6d. per 100. They give a good red heat, and last longer than any coal. Here is scope for turning the moors of the British Islands to a profitable use!

Another new kind of briquette has been invented by the Aktieslskabet den Tekn. Kem. Resin is melted in petroleum or other liquid combustible. The mixture is stirred for about ten minutes, during which time caustic soda is gradually added, and also sawdust or other filling. The process is finished when the product has acquired a sufficient consistency.

Hygienic Briquettes.—A briquette due to M. Auguste Saintaraille, is called the hygienic briquette, and is made by preparing a paste of two parts resinous wood shavings, one part powdered coal, and one part resin, mixed hot. The paste is compressed into moulds into the shape of Maltese crosses, which can be lit with a match. The combustion of these briquettes gives out a slight odour of turpentine, which is both agreeable and healthy.

Brisket of Beef.—F. *Brêchet de bœuf*; W. *Y barwyden.*

The brisket is the breast of the animal, or that part of the breast that lies next to the ribs.

Bristol Bricks.—See *Bath Bricks.*

British Brandy.—A common kind of brandy distilled in England from malt liquors, and given a flavour and colour more or less like French brandy by artificial means.

It may be called an artificial production, often made by adding to every 100 parts of proof spirit from ½lb. to 1lb. of argol, some bruised prunes, and a quart of good Cognac. The mixture is then distilled, and a little acetic ether, tannin, and burnt sugar added.

British Gum.—See *Dextrine.*

British Sherry is generally made either from Cape or raisin wine, or from dried raisins, flavoured with a little bitter almond cake (the pulpy mass remaining after the oil has been expressed from the almonds) or else the oil of almonds itself, and a very little of sweet-briar, orange water, or orris.

It is also sometimes produced from very strong pale malt wort, sugar, yeast, and rectified spirit, and flavoured.

British or **Home-made Wines.**—These are made up from various fruits, flowers, leaves, or spices, and most of them contain a great proportion of citric or malic acid, which acids are soluble and dissolve in the liquor. In order to neutralise this acidity it is the custom to add cane sugar (not *beet*), and only a little spirit to prevent the fermentation the sugar would cause. Hence the difference between wines made from the grape and those made from the gooseberry, etc. The use of unfermented grape juice is, however, now largely imported for British wine manufacturers.

British wines, although often drunk by teetotallers, are frequently stronger than many of the foreign wines, in consequence of the sugar employed being converted by fermentation with the raisins into alcohol. This, together with the spirit introduced before bottling to keep the wines clear, often amounts to 20 or 30 per cent. of true spirit, and, of course, renders the product a powerful intoxicant. (See *Sweets.*) On the other hand, British wines sometimes contain a great deal of unfermented sugar, or they have become "pricked" (see *Pricked Wine*), and are consequently apt to derange the stomach. Some of the very low-priced makes are nothing more than coloured water and

sugar mixed, with just sufficient of the refuse of distillery oil to keep it from turning sour.

At one time their manufacture formed an important part of the education of the good housewives of Great Britain, vide Goldsmith's "*Vicar of Wakefield.*" They were made from plums, apples, gooseberries, bilberries, elderberries, blackberries, currants, raspberries, cherries, cowslips, parsnips, raisins, greengages, damsons, rhubarb, ginger, oranges, and lemons. Less common were wines from mulberries, quinces, peaches, apricots, and from the sap of the birch, beech, sycamore, and other trees.

British port is often made from damson juice, with spirit and other ingredients; sometimes from old cider, elderberry juice, sloe juice, extract of rhatany, with rectified spirit and flavouring. Most of these British wines are referred to under their respective names. A retailer requires a five guinea annual licence, which begins on July 6th, and must have his name painted over the shop door.

Every holder of only a *retail* licence should carefully explain to his assistants that not more than *eleven* bottles must be sold at one time (as is clearly stated on the licence itself). Excise officers often trap juniors into selling or invoicing 14 or 16 bottles at once, and then a summons follows.

Brittany Butter. — See *French Butters.*

Broad Beans comprise the Long pod, the Windsor, the Aquadulce, and other varieties. In gardens they are usually sown between February and May in rows about eighteen inches apart and three inches deep, at the rate of a quart per row of forty feet.

Broccoli. —F. *Choux Italiens;* G. *Italienischer Kohl;* Lat. *Brassica botrytis;* W. *Math o fresych.*

This word was formerly spelt with only one "c." The plant is of very untrustworthy growth, only moderately hardy, and often killed wholesale in hard winters. In season during winter and spring; should have large white-hearted compact heads, and be free from any tinge of yellow or green, either of which indicates inferior quality.

Broccoli sprouts are purple in colour and not compact in the head. (See *Cabbages.*)

Brochettes. — See *Crystallised Fruits.*

Brom.—A Javanese beer obtained by the fermentation of rice, but not the product of distillation.

Broma.—A breakfast powder made by mixing 1lb. of pure cocoa powder with about 4 ozs. each of sugar and sago meal.

British arrowroot (prepared potato starch) is sometimes substituted for the sago, and occasionally wheat flour.

Bronze Powder and **Bronze Leaf.** —F. *Bronze en Poudre;* G. *Bronzefarben;* Sp. *Polvos de bronce.*

Are prepared in several ways.

(1) Of Dutch metal or gold leaf ground to an impalpable powder.

(2) Gold is dissolved in nitro-muriatic acid, and precipitated with a solution of pure proto-sulphate of iron, then washed and dried.

(3) Gold leaf is ground with honey to an impalpable powder, the honey then washed away and the powder dried.

(4) Gold leaf is triturated with crystallised sulphate of potassa, and the salt washed out with boiling water.

(5) A large quantity of Bronze Powder and Bronze Leaf is made in and near the cities of Furth and Nuremburg, in Germany. They are composed of copper, tin, zinc, and antimony melted in proper proportions. The cheaper qualities of powder are usually mixed with quartz powder to enable them to be sold cheaply.

Broom Corn.—A coarse grain plant raised in the United States mainly for the fibrous stalks, which are used for making brooms and brushes. Three-fourths of all the broom corn of the world is grown in the country around Arcold in Central Illinois.

Brooms.— F. *Balais;* G. *Besen* It. *Scope, Granate;* Port. *Vassoura*

Sp. *Escobas*; Rus. *Metlii*; W. *Banadl*.

Besoms or brushes, with long handles for sweeping floors, derived their name of *brooms* from being originally made of the broom plant, but the best, both for flexibility and durability, are made from ling, or heath.

They are now commonly made of bass (the well-known fibre of the Piassava plant of Brazil), birch, broom, or heath, also of bristles, sorghum stalks, etc.

Vast quantities of brushes, brooms, etc., are made in Southwark for the London markets. Birch brooms are most commonly used in gardens, and are those to which the name *besom* applies.

Metallic Comb Brushes have a large sale in India, as well as in Jewish communities, owing to the superstitious regard of the uncleanness of everything porcine, including bristles.

Broom-handles or *broom-sticks* are made by passing the stick longitudinally through the hollow mandrel of a lathe with internal cutters, and are thus rounded through their whole length. Large numbers are imported from Canada and the United States.

Brose.—See *Scotch Brose*.

Brou de Noix Liqueur. — A French home-made cordial, almost black in colour, prepared from young walnuts while green and milky. These are infused in spirits, and the product is finally sweetened and filtered.

Broussa Tea. — The leaves of *Vaccinium arctostaphylos*, Linn.; used at Broussa, and sold at about 8d. per lb.

Brown Boot Polishes.—For these polishes, creams, pastes, etc., take of Yellow Wax 3½ ozs., Yellow Soap ½ oz., Bismarck Brown 3 drachms, Potass Carb. 1 drachm, Boiling Water 10 ozs., Turpentine 10 ozs. Dissolve the soap, potash, and dye in the water, and add the mixture gradually to the wax and turpentine melted together. Rub together until quite cold. This will give a good non-sticky polish, if only a little be used at a time, and the boots will be well polished with a soft cloth after applying the paste.

Cream for Sea-Side Shoes.—Melt 300 parts of yellow wax on a water bath, and add 1,000 parts of oil of turpentine. Dissolve, separately, 120 parts of resin soap in 1,000 parts of water, and stir the mixture in with the wax and turps. When cold, a frothy paste results, which is coloured with a solution of 15 parts Nankin brown in 75 parts of alcohol.

Cream for Brown Boots.—(1) Mix 1,000 parts of yellow Petroleum Jelly, or Paraffin Wax, 70 parts of olive oil, 500 parts of ceresin, and 1 part of leather yellow. The last ingredient is added as a colouring matter to the hot mixture.

(2) Melt 4lbs. paraffin wax with 2lbs. napthaline and 1lb. soft soap; 1 gallon of warmed paraffin oil is then stirred in, and a little oil, brown colour, scented with mirbane, is added.

Special Manufacturers. — Day & Martin, Ltd., London and Liverpool (see adv., near end of book); E. Mitchell & Sons (tan polish), 5 Burnett Place, Bradford, Yorks; John Parkes & Co., Priory Works, Warwick.

Brown Bread. — See *Whole Meal Bread*.

Brown Windsor Soap. — See *Windsor Soap*.

Browning or **Gravy Salt** (sometimes called *Browning Salt, Brown Gravy Salt, Parisian Essence, Couleur Parisienne*, etc.).—A fluid preparation used to colour gravies, beef tea, soups, etc. A good one is made of following proportions—say 1lb. of caramel (burnt sugar), ¼lb. common salt, and half a pint of mushroom ketchup flavoured with spices. Some use strong beer, wine, or water, instead of the ketchup.

Special Firms.—Charles Cocks & Co., Reading, Berks; Allen Jeeves & Sons, Seddington, Sandy, Beds.

Brunswick Black.—(1) Generally made of asphaltum, boiled linseed oil, and oil of turpentine; say two parts of the first melted and mixed with one part of the second, and afterwards a sufficient quantity of the third stirred in to reduce it to the thinness desired.

(2) Take 7lbs. of pitch and 7lbs. gas-tar asphaltum, boil in an iron pot from seven to ten hours with frequent stirring, and when all moisture is out add two gallons boiled linseed-oil previously heated; then add 2½lbs. of litharge and 2½lbs. of red-lead, and boil for three hours, or until some of it will set hard. Then let it cool down and add five gallons of turpentine, or as much as will reduce it to the consistency required. When applied it should dry in from twenty minutes to one hour.

(3) If wanted cheap, and one hour will do, more oil and less turpentine is put in, and sometimes extra of asphaltum and less of red-lead.

(4) In the cheapest kinds common black pitch is used in lieu of asphaltum.

Special Firms.—Day & Martin, Ltd., London and Liverpool; John Parkes & Co., Priory Works, Warwick; Paton Calvert & Co. ("Komo" Black Enamel for Grates, etc., etc.), Leeds Street, Liverpool (see "*Komo*").

Brushes.—F. *Brosses;* G. *Buersten;* It. *Setole, Spazzole;* Port. *Escovas;* Rus. *Schtschetki;* Sp. *Brozas, Cepillos, Escobillas;* W. *Ysgubellig.*

Enormous quantities of fibres are used in brush making, after being steeped in hot water or steamed to make them supple and to prevent them breaking. A Madagascar palm has lately been found to yield a similar substance, and, more recently, the long coarse fibres composing the petioles of the wine palm of tropical Africa (*Rafia vinefera*) have been largely employed under the name of "Lagos bass," and still more recently another bass has been procured, Palmyra palm (*Borassus flabellifer*) of Ceylon and Southern India.

A selected stock of these, along with Brooms, Mops, Sponges, Chamois Leathers, Housemaids' Gloves, Mats, Kneelers and Boxes, Tamis or Tammy Sieves, Flannel, Toilet Combs, Curry Combs, Mane Combs, and Jelly Bags, forms an excellent and profitable auxiliary to the business of the family and country grocer. The most salable are sweeping brooms, scrubbing, shoe, banister, stove, plate, horse and flue brushes; crumb brushes, hair brushes; tooth brushes and nail brushes also sell well. The best brushes and brooms are those made of bristles, the long, stiff hairs which grow on the backs and necks of hogs in Russia, Germany, and other Northern countries; the white Okatka bristles from Russia being the best of all. Hat brushes, babies' hair brushes, boot polishers, etc., of good quality, are made of horsehair or strips of whalebone. The commoner sorts are usually made up of vegetable kinds and fibres, Esparto grass, Kitool fibre, etc. Bristles are of several colours; the whitest are called "lilies," and are mostly used for making best tooth-brushes; others are black, brown, grey, or yellow.

The Chinese black bristles, hard and brittle, with a glossy surface, are extensively used; but although they may be elastic and have an excellent spring, it is a metallic elasticity like fine steel wires, and they break off in use, thus wearing out faster than the Russian, German, and French, black or white, which are tougher, better, and much cheaper in the end.

Bristles are combed or "dragged" and sized according to length, and sold by "bristle merchants" in bundles, at prices varying from 1/6 to 30/- per lb., according to quality and length.

The best hair brush is made of all Okatka bristles to get stiffness; but they have to be of different lengths to render the brush penetrating, so as to enter the hair.

The high cost of bristles gives rise to all kinds of imitations, and it is not easy for a novice to distinguish a brush of genuine bristles from one made of other cheaper materials which are substituted, mixed, dyed, and glossed so as to deceive the public wholesale. Frequently the inner knots of a brush or broom are all composed of fibre, while the outside knots are of bristles of the same colour. Sometimes the materials are mixed. The fibre of the American agave and especially that of the broom corn (*Sorghum vulgare*) are largely used, also the leaf stalks of the African bamboo palm. As a rule, if a knot of

bristles be crushed or flattened down by the thumb it will right itself again quickly, but if of fibre it will remain crushed or crooked, and will not rise again.

Remove one or two of the suspected hairs or fibres from the brush or broom and burn it in the gas jet or candle, and the smell will show whether vegetable fibre or animal bristle.

True bristles will frizzle up and leave no ash, but fibre burns without smell and leaves an ash.

Jews, Turks, etc., who look upon the pig and all its belongings as vile and unclean, are much averse to using brushes made of bristles, hence must have articles made of horse or cow hair, fibres, etc. Retailers should remember this.

Brushes are now mostly made by machinery. The various knots of fibre are *punched into* the holes of the wood stock, which can therefore be made solid throughout. The punching is effected in such a way that the knot is held firmly in position by a piece of stout steel wire, which sticks in the sides of the holes. No pitch is used, and the brushes and brooms so made are able to withstand a good deal of rough usage.

Brushes are often spoilt by leaving them in water; the water not only injures the bristles, but melts the glue used in making the brush. When washed they should be dried quickly.

The best makers stamp their name or trade mark on every brush.

Brush, broom, and basket-making are industries which have been found to be specially adapted to the blind, hence here is a growing preference among the principal consumers for the articles produced by this afflicted class. They should be stamped "Made by the Blind."

Machine-made goods may be cheaper and look smarter, but the best judges prefer the hand-made.

Brooms and brushes of all sizes are best stored and displayed in a sloping show case, covered with a glass lid. The largest brooms are arranged at the back and the smallest at the front. The brushes are thus all kept free from shop-dust and unnecessary handling, and the customer standing in front can easily see every brush in the case—scrubs, shoe, stove, dandy, horse, clothes, bannisters, and brooms of hair, bass, or fibre. Without some such arrangement brushes soon get either soiled, misused, or mislaid, and unsalable. The case should be on the counter, and, if large enough, may also contain wash boards, tubs, pails, churns, and other whiteware.

Parnall & Sons, Narrow Wine Street, Bristol, also sell a very convenient and cheap stand for long-handled brooms and brushes.

Brussels Sprouts or **Borecole.**—F. *Choux de Bruxelles;* G. *Rosenkoln;* L. *Brassica oleracea fimbriata.* (See *Green Fruits*, etc.)

The favourite variety cultivated in this country are known as the Imported, although there are others stronger in growth and productive of huge sprouts.

They sell best in October, November, and December, and should be sown in Autumn or February or March. To make them "button" well, plenty of water and hardy growth is desirable. The largest and tightest buttons are the best, but loose or open sprouts are lightly valued.

Bucellas.—A rich dry, white wine, produced near Lisbon, in Portugal, from vines transplanted from the Rhenish districts of Germany. Bucellas usually contain about 12 per cent. of absolute alcohol, and seem to have the flavour and general properties of Rhenish wines.

Buckinghamshire Cheese. — A noted soft cream cheese, but, like most cream cheese, will not keep very long.

Buckwheat, Brank, or **Saracen Wheat.**—F. *Sarrasin, Blé Noir;* G. *Buchweizen, Heidekorn;* It. *Grano Saraceno, Faggina, Fraina;* Pol. *Tatarca, Gryka, Pohanka;* Port. *Trigo preto;* Rus. *Gretscha;* Sp. *Alforfon, Trigo Saraceno, Trigo Negro;* W. *Gwenith yr Hydd.*

The buckwheat plant, *Polygonum Fagopyrum esculentum*, is a native of Siberia, where it is extensively cultivated

as a bread corn. It is now grown very much in Holland, as may be inferred from the quantity of hyacinths and other Dutch bulbs coming over here packed in its dark brown husks; and is more cultivated in France (Brittany and Normandy), Germany, and America than in England, where indeed it is seldom sown except for pheasant food.

Buckwheat is not really a *cereal* or *grass* at all, but belongs to the *Polygonaceæ* family of plants, of which the rhubarb, the common dock, and several other weeds are also members. It grows two or three feet high, with a knotty branching stem of a reddish colour. Its leaves are ivy-shaped, its flowers are white and hang in bunches, and bees are particularly fond of them. The plant is an annual of easy culture, growing on the poorest soils, sandy heaths, moorlands, and requiring very little attention or manure. A sowing of 1 to 1½ bushels yields 30 or 40 bushels an acre, and weighs 46 to 48lbs. per bushel. It is sometimes sown that it may be cut young and green for cattle, or ploughed down green as a dressing for wheat. It will keep on flowering a long time, but unless harvested when the bottom seeds are ripe they will be shed and lost in the field.

The seeds resemble beech-nuts, whence the name (*buck*, beech), and make very good food for milk cows, hogs, poultry, as well as game, but are apt to produce skin eruptions on horses. In the backwoods of America they are ground and used as porridge or hasty pudding with maple honey, and considered very delicious. In fact, throughout the United States buckwheat is largely made into cakes or crumpets, and eaten for breakfast hot from the baker's. These cakes have great renown, but being deficient in gluten, the flour cannot well be made into bread.

Some of the buckwheat flours have been found to be adulterated with ground cokernut shells.

Buckwheat is used in much the same way in Brittany, Vendee, and the poorer districts in the centre of France, where "*galettes*" or "*crêpes*" (pancakes) are commonly eaten with milk. There is, however, a bitterness noticeable in most of these preparations.

Buckwheat is also extensively used in gin distilleries.

Buda or **Ofen Wine.**—An Austrian product once very popular in England.

Budram, Mwdran, or **Brwchan.**—A gruel made in Wales, by steeping oatmeal in water for 24 to 36 hours until it begins to ferment, and then boiling and skimming to the desired consistency.

Buhach.—See *Insect Powders*.

Bull Butter.—Spurious butter, made from fats and tallow of the abattoir instead of milk or cream; a rendering of all available animal fats. (See *Margarine*.)

Bullaces.—F. *Prunelles;* W. *Aeron Gwylltion.* (See also *Sloes*.)

A wild species of plum, *Prunus insititia*, the tree or bush differing from that of the common plum, chiefly in its dense bushy form, its spiny or prickly branches, and its smaller leaves. The fruit is round, of damson colour, about half the size of a cherry, and very sour. They are larger than sloes, but seldom gathered in England.

In France they are gathered and preserved in brandy like plums and cherries. They are also made into a special liqueur called *Prunelline*.

Bullet or **Bully-tree Milk.**—This is the sap or milk obtained in Dutch Guiana from the leaves of certain large forest trees of the Sapotaceæ order, called *Mimusops balota*.

It is chiefly extracted for the purpose of being made into *balata*, a superior species of gutta-percha. A gallon of milk will dry to about four pounds of balata. A considerable amount of the liquid is used by the bush negroes for mixing with their chocolate.

To drink spirits immediately after partaking of this bully-tree milk is well-known to be highly injurious.

Bummaloe Fish or **Bombay Ducks.**—Packed and retailed in 1/- tins. A small, glutinous, transparent kind of fish about the size of a smelt, found on

the coasts of Southern Asia, and when dried is much used as a relish by both Europeans and Indians. Often humorously called *Bombay Ducks*.

Bungs, Shives, etc.—F. *Bondes*; W. *Bwing*. (See also *Corks*.)

Bungs for casks are generally made of oak, beech, or sycamore wood, as being less porous than cork. Those circular discs, either of cork or wood, which are larger in diameter than in length, are termed cork shives, wood shives, white shives, or compressed shives. Shives vary from ⅞ to 2½ inches in width by about ½ inch in thickness. Soft wood shives may be ½ to 3 inches wide, and are sold at 1/4 to 4/3 per gross.

In driving in bungs, etc., the grains should be in agreement with that of the cask stave.

Buns.—The origin of the word is attributed to the old French word "bugne," signifiying a "swelling," hence "bugnet," the puffed loaf. But lexicographers do not like to be dogmatic, and prefer to leave the origin of the word "bun" in doubt. In the fourteenth and fifteenth century it had the shape of "bunne." In Hone's "Everyday Book" (1825) *hot-cross buns* are described as "consecrated loaves bestowed in the church as alms, and to those who could not receive the host, made from the dough from whence the host itself is taken."

There have been many accounts given as to the origin of these, but that given by Canon Donlevny, of Edinburgh, should be worthy of quotation. During the observance of Holy Week, the Church in early times was far stricter in the matter of fasts than she is now. Only a certain amount of bread could be eaten, and that was duly marked off in the dough by two lines to show its *length* and *breadth*. These loaves were sold in some churches, and were carried from place to place by pilgrims, and so the custom was continued of crossing the bread used on Good Friday long after the occasion for it passed away. It used to be a common belief that bread baked on Good Friday never grew mouldy, and the same belief has extended to hot cross buns, one writer suggesting that the spice preserves them. A piece of the bread baked on Good Friday was carefully preserved far on in the year, and it was considered a sovereign remedy against the house getting on fire. Others preserved a piece of it for whooping cough, and for giving to cattle to cure certain diseases. But in Asia Minor the belief as regards Good Friday bread was quite different. There, no one would make bread at all on that day, believing that the water so used would change into blood, and that when the bread was eaten a deadly sin would be committed.

Recipe for Hot-Cross Buns.—Two pounds of flour, half a pound of sugar, quarter of a pound each of butter and lard, one pound of currants, two ounces of yeast, and half a pint of milk. Method: Rub the butter and lard into the flour, stir in the sugar and currants, make a well in the centre, and put in the yeast moistened with half the milk warmed. Let stand fifteen minutes, mix with the rest of the milk warmed, and stand to rise about half-an-hour. Divide into small pieces which shape with the fingers into flat cakes. Place by the fire until well risen. Cut with a sharp knife in the form of a cross, and bake in a brisk oven. When baked, brush over with milk thickened with sugar.

Spices for Buns.—The following formulæ for hot-cross bun flavouring are those used in different parts of the country, and may be taken as the basis for essences; but the powders are preferable, as giving that amount of brown colouring necessary for hot-cross buns.

LONDON FLAVOURING.

Powdered nutmeg	... ...	6 ozs.
,, mace	... ...	1 ,,
,, capsicum	... ...	2 ,,
,, cinnamon	... ...	4 ,,
,, ginger	... ...	8 ,,

Mix lightly and sift.

ENGLISH PROVINCIAL FLAVOURING.

Oil of cloves	... ...	10 drops
Powdered nutmeg	... ...	2 ozs.
,, ginger	... ...	1 ,,

Mix intimately in a mortar.

Jamaica pepper	2	ozs.
Cassia	1	,,
Cloves	½	,,
Ginger	½	,,
Rectified spirit	14	,,
Water	6	,,

Mix the water and spirit, and make a pint of tincture from the solids by percolation. To the product add 30 minims of oil of pimento.

SCOTCH FLAVOURING.

Powdered ginger	5	ozs.
,, coriander	5	,,
,, caraway	3½	,,
,, pimento	6	drms.
,, cassia	6	,,
,, cloves	1	oz.
,, nutmeg	½	,,

Mix intimately and sift.

One ounce of any of these flavours is required for every 7lbs. of flour.

Burghall or **Burghul.**—A prepared food, or boiled wheat, split and dried in the sun. Much eaten in Persia and Asiatic Turkey.

Burgundy Pitch. — F. *Poix de Bourgogne.*

A resin obtained by making incisions in the bark of the spruce fir, *Pinus excelsa*, whence it flows thickly and languidly, and soon sets into hard and brittle flakes, gradually taking the form of the vessel into which it is run. It is of white, yellow, and reddish-brown colour, melts readily in boiling water or glacial acetic acid, and is very adhesive, with an agreeable aromatic odour. The genuine comes from Finland, the Black Forest the Vosges, and certain hilly districts in the centre and South-East of France, and is much used in medicine. It is not produced in Burgundy. A fictitious kind called Common Burgundy Pitch is made in England, but is weaker and of disagreeable smell.

Another common substititue is *Canada pitch*, or hemlock resin, obtained from *Tsuga*, *Pinus*, or *Abies Canadensis*, and collected chiefly in Canada, New Hampshire, and Vermont.

Burgundy Wines.—F. *Vins de Bourgogne.*

There are two classes of Burgundies, the wines of Nuits and those of Beaune. They are mostly red. The white wines of the Nuits district are not much thought of, but those of Beaune (*Côte d'Or*) are more popular as dessert wines. The best red wines of Nuits are:—Chambertin, Clos-Vougeot, Romanee-Conti, Richebourg, Saint Georges, Vosne, Chambelle, Morey, Nuits, and Premeon.

The Beaune red wines in order of merit are:—Beaune, Corti, Chassagne, Pomard, Volnay, Aunay, Mouthilis, Sauterne, Savigny, Givry, and Mercury.

As a rule Burgundies are more generous, sweeter, and less rough than claret. They contain about 10 per cent. of absolute alcohol. *Clos-de-Vougeôt* is produced from vines over 300 years old. This with *Romanée-Conti*, *Musigny-Chambertin*, *Nuits*, *Richebourg*, *La Tache*, *Corton*, *Volnay*, *Pomard*, and some others, all rank as delicious and delicate wines. Unfortunately, they travel badly, while Bordeaux wines are much improved by transportation. The best for travelling is *Corton*, a sound and enduring kind. *Mâcon* and *Beaujolais* are also Burgundies, although better known by their own names, the latter taking its name from the district around the old town of Beaujeu. Of the *White Burgundies*, the best are those of the Beaune district, *Montrachet*, celebrated for its high perfume, *Blagny*, *Meursault*, the beautiful amber-coloured *Goutte d'Or*, *Buxy*, *Pouilly*, *White Mâcon*, *Vaumorillon*, and *Chablis*, which latter is a white dry flinty-tasting wine. Burgundies are very popular in France, and in the last century a remarkable controversy set in between professors of physic and men of science as to the comparative merits of Burgundy and Champagne. It lasted nearly a hundred years, when a solemn decree was pronounced by the doctors in favour of Champagne. The great Napoleon did not, however, agree to the verdict, and he continued to patronise *Chambertin*, a celebrated kind of Burgundy. The Burgundy district adjoins that for Champagne, and produces some 75

million gallons a year, and there has been a considerable increase in the British consumption of this wine during the last four or five years.

The name "Burgundy," as with "Champagne" and "Madeira," has now been made a regional appellation, and under no pretext will it be allowed as a generic term.

Burmese Pickled Tea. — Also known as *Leppett* or *Letpet Tea*

This is an article of local commerce in Burmah. Most of the pickled tea consumed by the Burmese is grown in Yaung Baing, or Tawng Peng, in the Northern Shan States, the whole State being given up to the industry. The plant yielding this tea has now been identified as the ordinary Assam tea plant (*Camellia theifera*), and often grows 60 feet high. Two crops are secured each year, only the young and tender leaves being taken. These, while still green, are thoroughly boiled in large narrow-necked pots made for the purpose, and are then poured into square pits dug in the ground about 6 feet deep, the side and bottom being lined with walls of plantain leaves, which prevent contact with the earth. The pit being filled with boiled tea and the juice from the pots, plantain leaves are placed on top and earth piled above these, stones and other heavy weights being placed on top. The pits are opened after some months, when the trading season begins, and the tea is sold to traders, who come with their caravans of bullocks to carry it down the Government road to Maymyo for sale in the Mandalay markets in long baskets, so packed that fermentation is prevented. In Upper Burmah and the Shan States the tea is sold in a dry state, and is prepared by boiling in an earthen kettle, salt being added when it is drunk. In Lower Burmah, however, it is largely consumed in the solid form, the leaves being soaked in oil, a little garlic or dried fish being added, and in this form it is regarded as a great dainty. Pony caravans from Hsipaw also carry it for sale to Mandalay and other neighbouring markets, and the Flotilla Company's steamers on the Irawady often carry hundreds of baskets of this tea as deck cargo. (See "*Watts's Dictionary of the Economic Products of India.*") At all family festivals it plays an important part, and no ceremony is complete without it. In the Upper Chindwin there is a trade in the seed as well as in the leaf. The leaves when picked are thrown into an iron cauldron full of boiling water, where they remain until they assume a yellow colour, when they are rolled by hand on mats, and are then ready for the traders, who carry them away in bamboo crates. If the tea is to be kept it is either buried in the ground or the crates are sunk in water. The seed, when intended for sale, is dried in the sun and carried away by the traders in mat-lined boats to a convenient landing-place, whence it is carried on coolies' backs to Manipur and Assam, where it has an excellent reputation for its germinating properties.

Little care seems to be taken of the gardens, which are situated on very steep hill sides; but they are wonderfully healthy, and if labourers can be got, a planter has only to search for the *red earth* areas, which are numerous all over the Upper Chindwin.

The plants become large enough to give a crop in three years if the garden is kept free from jungle; seed is borne in eight years, and in 15 years the trees are in full bearing, their normal existence being 40 to 50 years. Some 600 tons of tea is dealt with in this way yearly. The profits on the trade seem to be enormous; tea bought at the gardens at from 15 to 25 rupees for 360lbs. is sold in Mandalay at from 60 to 140 rupees. The trader makes over cent. per cent. profit on his outlay, and if he makes advances this is doubled.

Burnt Almonds or **Roasted Almonds.**—Used to colour and flavour liquors, also prepared with sugar, and dyed as a sweetmeat.

Burnt Cork.—See *Spanish Black.*

Burnt Sugar Colouring. — F *Caramel;* G. *Gebrannter Zucker, Zucker-couleur;* It. *Caramelle;* Lat. *Saccharum ustum;* Sp. *Caramelos.*

Burnt Sugar, *Caramel*, or *Sugar Colouring*, as it is indifferently called, is prepared in three forms:—(1) as crystals, (2) as a fine powder, and (3) as a thick and almost black syrup resembling treacle. The latter is the sort most commonly met with, and the best of it is made by heating *crystallised cane* sugar (not *molasses*) in an oil or metal bath to 210° or 220° C., when it begins to assume a brown colour, which goes gradually deeper. When the tumefaction is complete it is dissolved in water, and then concentrated by evaporation. It afterwards dissolves readily in water, and is employed in colouring wines, spirits, beer, vinegar, aerated waters, sauces, soups, gravies, and many other liquids. Good Caramel should give a *clear* solution, free from sediment, and without developing fermentation. If used in large quantity, or of low quality, it is apt to precipitate in the liquid to which it has been added, thus forming a muddy deposit or imparting an undesirable flavour, and giving much trouble.

Caramel occurs, as a matter of fact, during the roasting of all materials containing sugar, such as coffee, malt, etc.

Foreign caramel is imported in kegs of 1 and 2 cwts., also in casks of 4 to 9 cwts. Most of this is made in Germany from potato starch, or rather burnt glucose. Ordinary Caramel for colouring vinegar, etc., may be bought at 17/- to 22/- per cwt. For Brandy colouring, soluble in 10 per cent. O/P, 25/-to 30/-. For Rum colouring, soluble in 50 to 60 per cent. O/P, 35/- to 50/-. (See *Flash.*)

For colouring spirits the Caramel used should depend on the strength of the spirit. In fact, much depends on the purpose for which it is required, and when for use in colouring valuable liquids, it is decidedly safest to buy from firms of repute irrespective of a few shillings in price.

Burr Tea.—A beverage prepared by colonists of New Holland from *Acæna Sanguisorba.*

Burriana.—A kind of fruit grown in Valencia.

Burton Ales.—(See also *Ales.*)—The famed ales of Burton-on-Trent, in Staffordshire, which are the strongest kind in general use, are brewed with hard water, and, in fact, they owe their excellence in a great measure to the hardness of the Burton water, the River Trent containing an unusually large proportion of sulphate of lime, together with carbonate and muriate of lime. These exert a considerable depurative power on vegetable juices, superseding the necessity for finings; thus the ales brewed from this water become bright and clear almost immediately. The water from some of the Burton wells is so hard and salty that peas boiled in it are almost uneatable. Some brewers to make soft water like a Burton one, add four parts of sulphate of calcium, three of salt, and one of sulphate of magnesia; while others use specially-prepared hardening compounds, such as "Burton Crystals" or gypsum, for the same purpose. It was about 1823 that the idea occurred to the Burton brewers to produce Pale ale in competition with the Indian ale, but it was not till 1851 at the Great Exhibition in London that the Burton brew became popular.

Bushel.—F. *Boisseau;* W. *Pwysel.*

An imperial bushel is equal to 4 pecks, or 8 gallons, or ⅛ of a quarter, or 80lbs. avoirdupois, of distilled water, or 2218·192 cubic inches. The *Winchester bushel* contains 2150·42 cubic inches.

Bussorah or Basrah Dates.—See *Dates.*

Butter.—Da. and Sw. *Smor;* Du. *Boter;* F. *Beurre;* G. *Butter;* It. *Burro, Butirro;* Pol. *Maslo;* Port. *Manteiga;* Rus. *Masslo Korowe;* Sp. *Mantecilla;* W. *Ymenyn.*

There are in commerce several kinds of butter: Cocoa-butter, Dika-butter, Kokum-butter, Mahwa-butter, Nutmeg-butter, Shea-butter, but these are dealt with elsewhere, under their respective headings. Cow butters are the substances now before us. The first mention of butter is made in "Plutarch's Life of Caius Cæsar," when, at a banquet given in honour of the great

captain at the house of Valerius by the Milanese chieftains, "asparagus cooked in butter" was served up. The butter produced in England is of little importance, and most of that sold in the shops is of Irish, Colonial, and Foreign make.

besides some 50,000 tons of foreign margarine and about 30,000 tons of condensed milk.

With one cow to each ten of the population, England cannot possibly supply sufficient milk for the butter, cheese, etc., she annually requires, and her farmers profess to make better use of their time than butter-making.

Copenhagen has lately been ruling the prices of finest mild butters, and Danish has also been fetching the highest prices, but some authorities predict that Australian, Tasmanian, and New Zealand butters, which come frozen or *chilled* in firkins and cases, seem likely to oust some of the foreign importations. The frozen appears to keep the best; but butter merely chilled, or that kept long in cold storage is apt to lose flavour, go mouldy, and turn out very unsatisfactory.

Friesland Factory Butters come in 56lb. kegs.

Irish, in rolls, lumps, kitts, pyramids, and firkins (see *Irish Butter*).

Italian is generally very poor and insipid.

Canadian and other imported kinds are sometimes sold as "Prime Dorset" or "Best Devonshire," which is, of course, grossly unfair both to the English producer and to the consumer.

Devonshire Butter is usually made from scalded cream.

Cream.

Further information will be found under these headings.

The makers of Danish and Norman butters are by their co-operative and factory systems simply cutting the English farmers out of their own markets. The foreign article can, while fresh, be more depended upon for uniformity and regularity in delivery.

The annual consumption of butter per head is in England, 13lbs.; Germany, 8lbs.; Holland, 6lbs.; France, 4lbs.; New Zealand, 20lbs.

An average English cow in full milk should give 150 to 180lbs. of milk weekly, or, say, 600 to 700 gallons yearly; and about 2½ gallons yield 1lb. of butter. The amount of fat in butter ranges from 80 to 90 per cent., water 7 to 16 per cent. If more of the latter, it is injurious to the keeping properties of the butter, and liable to fine. Good qualities contain only 10 to 12 per cent., and *Salt* butter not more than 16 to 18 per cent. of water. Good colonial butters rarely contain more than 6 to 12 per cent., and Danish not more than 16.

By a mechanical process considerably more water may be incorporated, and analysts have been finding 20 to 25 per cent. in Irish; in one instance on record 42 per cent. of water was found.

Creamery Butter is butter made in factories which receive fresh milk from a number of the neighbouring farmers.

Factory Butter is a name given to butter blended on the Brittany plan, from the smaller farmers and cottagers either

at the factory or at market towns, which is mixed together, washed, and improved much as possible for resale and export in large quantities of uniform qualities. (See *Blended Butters.*)

The amount of salt employed varies from 1 to 15 per cent., and even 28 per cent. has been found; but there seems to be no clear distinction between salt butter and fresh butter; a degree of saltness allowed fresh butter in one county might constitute salt butter in another.

In Scotland fresh butter must be absolutely free from salt or any other preservative, but in England it may contain 1 or 2 per cent. of salt. Danish butter usually contains 1 per cent.

If the butter be badly made, salt may hasten its spoiling; if well made, salt may spoil its delicate flavour.

In regard to purity, it has not yet been clearly defined what purity in butter is; and there is no fixed standard. Hot brine is, no doubt, often purposely used to make it absorb as much water as possible, and farmers' wives have been heard to boast how many pints of hot water they could get into their butter.

The other ordinary adulterants of butter, besides water and salt, are animal and vegetable fats, boric and boracic acid—the latter, although professedly used as a preservative, is really considered an adulterant. Butter colouring is not much used in Scotland, although it is used almost everywhere in England and abroad, and it undoubtedly helps the sale of butter to place it in the market a nice bright lemon or primrose colour. Great care should, however, be taken not to choose cheese colour or an inferior annatto, as these produce a dull brick-red colour that injures the butter and also colours the butter-milk. The colouration with annatto is also objectionable, in view of the fact that this dye-ware is often worked up with stale wine, and has been found swarming with microbia.

Another undesirable colouring ingredient has recently come into use, viz., yellow azo dye-stuff. To detect it, take a small piece of butter, about the size of a walnut, and spread it out upon a white dinner-plate. Next take a pinch of fuller's earth (take care that it is not perfumed), and stir it into the butter; then watch the results. In a few moments a pink to a violet-red colour will appear if any of the yellow azo colouring-matters are present. The presence of a slight trace of the dye is indicated by the pink coloration, and the colour deepens according as there is more dye present.

How to detect margarine or foreign fats in butter.—Various methods have been invented, but the specific gravities of butter fat and foreign fat and their respective melting points perhaps afford the readiest means of distinguishing. Analysts are usually guided by the difference in the proportion of soluble and insoluble acids. If a carefully-selected fat has been substituted, it is best detected by examining the sample through a microscope under a polarised light. The following is considered a good test:—

Into a tubular glass called a *lactocrit*, properly divided and marked, which is placed in warm water, and which contains 1·5 cubic centimetres of sugar syrup, the butter which is to be tested is gradually introduced until there is altogether 10 cubic centimetres. The glass is then closed, slightly shaken, and placed in a wooden cover, which is swung very quickly round for a few moments by a string tied to it. Thus melted, the butter becomes divided into three layers: the outside consists of water, the central of butter fat, and the middle layer is a white emulsion most plentiful when the butter is pure, but never present in margarine; also if the butter be pure the fat is transparent in addition to the white emulsion being voluminous, but if the butter contains margarine the fat remains milky.

An easy method to distinguish margarine from butter is to take some pure butter and the suspected sample, and, after melting them both at the same temperature, to drop them on the same glass plate side by side. The margarine (or tallow) drop will be full of minute crystals (little white dots), but the pure

butter (or spermaceti) drop will show no crystals. An experimenter may quickly learn the difference in the patterns of such drops.

The character and purity of butter may also be examined by testing its refractive power. The apparatus of Amagat and F. Jean is very easy to use, and by means of this instrument the deviation of pure butter of the best quality is + 35°; that of margarine only + 5°; cotton-seed oil + 20°; while lards and suets give—deviations. A simpler test is to place pure butter in a test tube of thin glass and hold it over a gas jet, when it will soon froth; the more and easier it froths the less water there is in it. But place margarine in a test tube and heat, it will froth very little unless its butter percentage is high, and if milk has been used it will, along with other added matter, form at bottom as dross and can be estimated. Vegetable fats melt and remain as clear oil.

Test for Margarine and Lard.—Stir a little—half a teaspoonful or less—of the butter in enough sulphuric ether to dissolve it. By the time the grease is dissolved the ether will have evaporated, and the residuum will show, to smell or taste, whether it is butter, lard, or tallow. Two pennyworth of ether will suffice for several lots.

Again, pure butter yields a clear liquid on melting 10 grains in a test-tube, adding 30 minims of carbolic acid (Calvert's No. 2, diluted with one-eighth its weight of water), shaking, warming till clear, and allowing to stand. Most other fats form two layers.

Other rough and ready tests for margarine.—Take two or three pieces of sewing cotton lightly twisted together, and drew them through the substance to be tested. Then set the cotton alight and blow it out almost immediately. Smell at the cotton, and if it contain much margarine it will have the smell of a newly extinguished tallow candle, but the purer the butter the less smell there will be. Or, place a piece of clean lamp or candle wick in the suspected article and set it alight, margarine will smell more or less tallowy, and butter buttery. Margarine and fats may often be detected by the smell after rubbing them violently in the hands. Real butter also melts readily at a lower temperature than margarine. A solution of carbolic acid will melt butter, but it only slightly affects margarine. Again, if a piece of genuine butter be melted in a glass, there will be a residue of salt and water, but the melted butter itself will form a clear and transparent substance of pure natural butter. Now, if one takes a piece of margarine the melted substance has a milky appearance and is not transparent. A mixture of margarine and butter has, therefore, when melted, the degree of milkiness proportionate to its impurity.

Every well-wisher to the poorer classes must be glad to see margarine obtainable, but not palmed off as genuine butter.

Rancid Butter.—To restore this, use one pint of water to each pound of butter, previously adding 20 grains of chloride of lime to each pint of water; knead or wash the butter well in this mixture, afterwards re-wash in clean brine and flavour; or melt the butter in a water bath with animal charcoal, coarsely powdered, and previously well sifted to free it from dust; skim, remove, and strain through flannel, and then salt. The rancid flavour may also be got rid of by kneading the butter in water containing a small quantity of bicarbonate of soda.

Another method.—100lbs. is placed in about 30 gallons of hot water, in which ½lb. bicarb. soda and 15lbs. fine granular animal charcoal, free from dust, has been mixed, and the whole is churned together for some 30 minutes. The butter is next separated, warmed, and strained through a linen cloth, then resalted, coloured, and, if considered satisfactory, finally worked up with one-half its weight of fresh butter.

A better and simpler method is to wash the rancid butter with some fresh new milk and next with cold spring water. (Butyric acid, on the presence of which rancidity depends, is freely soluble in fresh milk.)

How to cut Butter.—It is a well-known fact that in the churning process the small fatty globules previously floating in the milk become concentrated and formed into a solid substance—butter. It is said there are about four millions of these globules in a pound of butter. Now the more these globules are bruised, burst, or cut, the sooner the butter goes bad. The experienced butter salesman, therefore, will always use a wire. After the tub has been turned out, he will cut the butter horizontally about the middle; then cut perpendicularly the upper half into two equal parts, and place these halves on the top of each other with the cut parts facing outward. In cutting the first few pounds and half-pounds from the top, he will cut them from the bottom half. He will not have any pieces lying about; he will never touch the butter with his hands; and he will not wipe his knife on the edge of the tub and leave scrapings there every time he serves a customer. Good butter-cutters can cut a pound of butter nine times out of ten just to the ounce, but the inexperienced always cut too much, and have many pieces lying about. If you are waiting on adults and cut too much, just mention it, and they will nearly always take it, and save you from cutting off; but when a child asks for a certain quantity give just what is asked for. It looks very disgusting to see a tub of butter all covered with pieces, and where the knife has been scraped on the edge of the tub.

Do not stick your knife in the butter when not in use. If your butter is turned out on slabs, and the salt should make its appearance on the sides, take a clean cotton cloth, wet it, and wrap it round your butter every night, and it will look fresh every morning.

To prevent butter sticking to the slab, slicer, beater, etc., scrub them every morning with soap and boiling water, and afterwards keep slicer and beater in cold water, and the slab wet.

Butter should, as a rule, be kept separate from everything else, as other goods are liable to change its flavour. It does, however, derive an agreeable aroma from a proximity to oranges. There is a very common mistake made in keeping sweet butter, namely, in water. This very quickly injures the flavour of it. It should be kept in a cool, airy place, but perfectly dry. When butter is made up in small fancy shapes, and kept for two or three days in water, the flavour is affected, and the butter more or less injured.

In sampling butter the novice should take care in withdrawing the auger or sampler, to keep turning it round on its axis.

The most approved packages for butter are made of white Danish beech-wood, purified so as not to colour or flavour the contents. Frequent complaints are made of mould in imported butters. Mould is very infectious, of rapid growth, and not easily eradicated. It often arises from mouldy cellars or warehouses or other close stuffy places. Butter should be stored in dry and airy situations. Some attribute the mould largely to the inferior grease-proof paper often used for lining the packages or wrapping the butter. The following precautions are recommended:—(*a*) The removal of mould or mould germs from the casks by their being scoured, brushed, and rinsed in water to which soda or salt has been added. (*b*) The destruction of possibly existing organisms by steaming the casks with hot steam for five to ten minutes. (*c*) Soaking the paper in a strong solution of salt, or steaming it (for this purpose place it folded on the bottom of cask before steaming). (*d*) Protecting the casks inside, the paper, and butter from germs which might fall upon them from the air or the clothes of the person handling them. (*e*) Using as tight casks as possible, and packing the butter as carefully and firmly as possible, avoiding empty spaces. (*f*) Lining the casks in the warm season with thick parchment paper (No. 2, 3, or 4), or using two layers of paper—for instance, No. 4 outside and No. 7 nearest the butter. (*g*) Rubbing the inside of the cask with salt immediately before placing the butter in it (the salt should previously have been

placed on a hot stove for half an hour, and should be kept in closed stone or glass jars). (*h*) The casks with butter should be kept in as cool and dry a cellar as possible—in cellar for choice with a temperature of 4 to 5 degrees centigrade.

Special Firms.—Geo. Wall & Co., Ltd., 14 to 26 Williamson Street, Liverpool; established over thirty-five years; receivers of the finest selected Danish butter; this firm now has also the selling of the butters from some twenty creameries situated in the richest butter districts of Ireland (see advt., p. 10). Henry Bird, 15 Farringdon Road, London, E.C. John Hayes (butter exporter), Tralee, Ireland. W. A. McKnight (Canadian and States), 24 Mathew Street, Liverpool. J. J. Metcalf & Co., 45 Whitechapel, and 21, 23, and 25 Sir Thomas Street, Liverpool. Morris & Jones, 13, 15, and 17 Sir Thomas Street, Liverpool. R. Rutherford & Co. (all kinds), 112 Whitechapel, Liverpool. Thomas Wilson & Co. (Danish and Irish), 3 Hood Street, Liverpool.

Butter Beans.—A variety known as the *Haricot Beurre*, or butter haricot, so called from its light yellow pod, is boiled whole and then fried in melted butter or oil, forming a very delicious adjunct to the dinner table. This long-neglected variety has of late become materially popularised, and is now being largely cultivated. Large quantities are grown in Peru, and hence often called *Lima Beans*.

Butter Colourings.—Formerly the juice from grated carrots was mixed with the cream, but the large quantity necessary tended towards early deterioration of the butter.

A substitute was next found in paste annatto, an article obtained in the West Indies and South America by the fermentation of the seed of annatto.

Between 1860 and 1870 commercial butter colourings were introduced, and alkaline solutions obtained from annatto were used both for butter and cheese. These coloured the butter-milk as well as the butter-fat, but latterly vegetable oil has been used more extensively for butter colouring.

This is entirely absorbed by the butter-fat, leaving the butter-milk uncoloured.

If the oil used be pure, and one that does not easily get rancid, the colour is absolutely harmless. Many butter colourings consist of a mixture of about 40 per cent. of chrome yellow with some fat coloured with annatto, while competition has led some manufacturers of these colours to make their preparations stronger and stronger, overloading the oil with more colouring matter than it can hold in solution when exposed to various temperatures, age, etc., and these have a tendency to separate to some extent unless the bottle is well shaken before using.

In France also annatto (*roucou*) is used for this purpose. It is imported in the form of paste from Cayenne and the West Indies, and then mixed with olive oil and saffron to the shade desired.

Butterine.—A conventional name applied a few years ago to the artificial butter made by churning oleomargarine (a product of animal fat) with milk, water, etc., but on the "Margarine Act" (1887) coming into force all such substances sold in the British Isles were ordered to be labelled *Margarine*.

Butter-Milk.—F. *Babeurre*; Per. *Dook*; Port. *Soro*; Sp. *Suero*; W. *Llaeth enwyn*.

The liquid that remains in the churn after the butter is removed.

Its average composition when fresh is 90·62 per cent. of water, 3·78 casein, 1·25 fat, 3·38 milk sugar, ·32 lactic acid, and ·65 of ash.

The lactic acid increases with age. It is never fat-free, and really contains all the constituents of milk; but a great portion of the sugar has been changed into lactic acid. It often contains much of the salt added to preserve the butter.

Being exceedingly wholesome and nutritious, it is often taken with fruit, puddings, cakes, mashed potatoes, etc.; and is said to allay the nervous irritability caused by excessive tea-drinking. It is also good for rickets, diabetes, and many stomach affections, and some say it induces longevity.

Separated milk must not be sold as butter-milk.

Butter Nuts. — (Botanical name: *Caryócar.* Synonyms:—*Pekea,* and *Rhizobolus.*)—The fruit of a North American species of white walnut tree, *Júglans cinerea,* so called from the oil the nuts contain.

Butter-nuts are of oblong shape, about two inches in length, round at the base, sharp at the point, and viscous.

The kernel is sweet and pleasant to the taste when fresh, but contains so much oil that it soon goes rancid.

Butter of Mace.—See *Mace Essence.*

Butter Powders.—These generally consist of bicarbonate of soda coloured with either a little turmeric or annatto. (See *Butter Colourings.*)

Butter Scotch.—A very nice butter scotch may be made as follows:—

Take 1lb. of the very best of butter, put it into a clean white pan or basin, and melt it down, stirring steadily with a wooden spatula; then add to it 4lbs. of best sugar; continue to stir and boil it to the *crack,* then pour it, about a quarter of an inch thick, upon a marble slab that has been previously rubbed over with olive oil or butter, or it may be poured into greased tins. When it has sufficiently cooled, cut or mark it into tablets. It may be flavoured with lemon or vanilla whilst boiling, or it may be left plain, as you please, but it is best to add the lemon late as possible, so long as it will incorporate with the sugar. Some add a little ginger, in which case the ginger is boiled in with the sugar.

Butter Soap or **Sapo butyricus.**—Soap made of soda and butter.

Byrrh.—A tonic wine or liqueur not unlike Quinine Wine. It is a combination of quinine with the red wines of Collioure, Banyuls, or Malaga, and fortified with alcohol. First made about 1873, and is now a speciality with Violet Freres, Thuir, Pyrenees-Orientales.

C

Caamina.—This is a name given by the Spaniards and others to the finest sort of *Paraguayan tea.* The shrub grows wild and is used in Chili, Peru, and other South American countries as tea is with us.

Caasnini and **Caanana.**—See *Maté.*

Cabbages. — F. *Choux;* Port. *Couves.* (See also *Cauliflower, Red Cabbage, Brussels Sprouts, Sour Crout,* etc.)

Broccoli, Cabbage, Cauliflower, Kohl, Brussels Sprouts, etc., have all been cultivated from one or more species of Brassica, and chiefly the Common Cabbage, *B. oleracea,* a native of the rocky parts of the sea-shores of England and Scotland, and which is said to possess in its wild state a most nauseous taste. They will grow in almost any soil, but prefer a light stony one.

Cabbages have been in cultivation for ages, and the original plant has given rise to several very curious races of esculents. In the Channel Islands, by picking off the lower leaves, the stem is made to grow to a height of 12 feet or more, and is used for walking sticks. Borecole, or Cow-cabbage, are forms with loosely-arranged, enlarged, and fleshy leaves termed *forma acephala.* Those in which the leaves are in a more compact and rounded head, including the *Red* Cabbage and the *White* Cabbage, are said to be *formæ capitatæ;* and those in which the disc of the leaf is increased, so that its surface rises into little hollow projections (*forma bullata*), are Savoys or Curled Kale. A number of small leaf-buds on the stem (*forma gemmifera*) constitutes Brussels Sprouts; and an abnormally enlarged, branched, and fleshy flower-stalk with abortive flowers (*forma Botrytis*) is the Broccoli and Cauliflower form.

In one variety or another they are in season all the year round. They are more nutritious, especially cauliflowers, than any other vegetables, unless it be

mushrooms. The dried leaf usually contains 30 to 40 per cent. of gluten, which in potatoes, for instance, is nearly absent, and dry cauliflowers contain even 50 to 60 per cent. Boiled and eaten in conjunction with potatoes and pork fat, cabbages are really an excellent and valuable food. They should be chosen crisp, firm, and with large hearts.

The small Savoy is usually in good condition from May to August, while Brussels sprouts are seasonable all through the year.

Cabrillion.—A French name for the small cheese made around Auvergne and Lyons from goats' milk.

Cacao. — See *Cocoas*, *Raw* and *Manufactured*.

Cacao Butter. — F. *Beurre de Cacao;* G. *Kakaobutter;* It. *Burro di Cacao;* Lat. *Oleum theobromæ;* Sp. *Manteca de Cacao.* (See also Cocoa-nut oil, *Mafurra Tallow*, etc.)

This is commonly called Cocoa Butter, but is quite different to Cocoa-nut Oil or Butter, so it is here spelt Cacao for the sake of identity.

Cacao butter, that is *Oleum Cacao Concretum*, *Oleum Theobroma*, *Butyrum Cacao*, as the chemists variously call it, is a white or yellowish concrete oil or fat obtained sometimes by heating and grinding the seeds or beans of theobroma cocoa into a liquid state, when the oil or fat rises to the surface, and on cooling sets or cakes in the form of butter or tallow, but of firmer consistency. Sometimes suspended in bags to filter through in the ordinary way. More often, it is extracted by powerful hydraulic pressure, the beans being gently heated over a fire, then decorticated, and placed between hot iron plates; but quite recently a German firm brought out a patent process for the thorough extraction of cocoa butter without the aid of pressure. The method is somewhat similar to that adopted in the orthodox Turkish bath, for the oleaginous matter is literally sweated out of the cocoa. The apparatus is circular in form, and first lined with felt, then with calico or linen. The cocoa is put in in small quantities, so as to gradually coat the lining whenever a rotary motion is imparted. The speed is increased very considerably, and then very hot air is introduced. The cocoa powder resultant is the very driest of powder, and virtually all the butter is extracted. In some cases the extraction of the fat while in paste form is assisted by the addition of water.

Cacao butter has an odour resembling that of chocolate and an agreeable, bland taste. In fact, the essential oil is the fat, and, if this be completely extracted, the true flavour is lost to the cocoa drinker!

Pure roasted cocoa deprived of its husk consists of about 50 per cent. of this "butter." It has a special characteristic in that it never turns rancid, however long it be kept. When fresh it is yellowish, but becomes white on continued exposure to the air, and melts at 85° to 95° F. Mostly used in making the white creamy inside of "*Chocolate Creams*," also for ointments and other pharmaceutical preparations, as well as perfumery; and a little is professedly used in making some of the cocoa butter soaps, but very few of these soaps contain any of this rather expensive ingredient. Cacao butter, although a purely vegetable product, is often adulterated with tallow, lard, cokernut oil, sesame oil, tallow, white wax, stearic acid, etc. But in the genuine article we have a sweet vegetable fat, suitable not only for the scrupulous Hindoo, who will not use animal fat, and the prejudiced Mahommedan, who avoids the use of hog's lard, but also for the fast days of the Roman Catholic. Wholesale, in tablets or blocks, from 1/- to 1/4 per lb.

Besides what is obtained as a by-product in the manufacture of thin cocoas, cocoa essences, etc., in this country, a considerable amount is now imported, and especially from Holland, which sends about 900 tons a year in 2 cwt. cases. Until 1896, it was imported duty free, but, being now classed as a cocoa product, the duty of 1d. per lb. is levied upon it. Cheap stearine from Denmark has recently come into competition with cacao butter.

Cachous or Breath Perfumers.—F. *Cachou;* G. *Kaschu;* It. *Cacciu;* Sp. *Cachunde.*

A sweetmeat or small lozenge, often made round like a pill, and composed of extract of liquorice, cashew nuts, with gum, etc. Intended for smokers and others, for sweetening the breath.

Cacio Cavallo.—This is the name of the typical cheese of Southern Italy, also made to some extent in Lombardy. It is very palatable and nutritious, and considered a great delicacy. Made from sheep's milk. The inferior sorts sometimes have an obnoxious odour of the sheep. The chief centres of its production are Asso Romano, Albruzzi Puglie, and Calabria.

Caerphilly Cheese.—This is the cheese *par excellence* of Wales, and is produced around the little market-town of that name in Glamorganshire, where a market for it has been in existence from a period beyond memory. It is not much known elsewhere, but is as popular in every Welsh county as Cheddar is throughout England.

It is claimed for it that, owing to climatic influence, combined with suitable herbage and the formation of the soil, this unique cheese can only be produced in the above district and a certain part of Monmouthshire, west of the River Usk.

The great variation which, however, exists among these cheese and even in cheese from the same farm is a great drawback to its sale. The Caerphilly authorities some time ago resolved that every cheese passing through their market should be branded, but much is still sold in distant places as "Caerphilly," which is not made there but in Somerset and Gloucestershire.

Cafe Noir Biscuits. — Square shape, length 3 by 2 inches, and nearly ¼ of an inch thick; about 32 to the lb. It is highly baked. The upper-side is pricked, and the material similar to Osborne or Oswego, while the under-side has a coating of hard and smooth brown icing. The whole biscuit is strongly flavoured with vanilla.

Caffeine. — F. *Caféine;* G. *Kaffein;* It. and Sp. *Cafeina.*

The active principle in coffee and an alkaloid identical with *theine* (which see), but obtainable from coffee. It is white, bitter, and crystallisable, and was first discovered or isolated in 1820 by Runge, Pelletier, and others. It is also present in tea, cocoa, guarana, coca, kola, yerba mate, etc. It possesses highly stimulating qualities, but its effect is not followed like that of alcohol by depression, and it renders coffee a valuable antidote to nicotine (tobacco poison). It is a very powerful drug, and is frequently used to relieve headache; it stimulates the heart, and increases the amount of urine passed. Used in excess, caffeine causes palpitation of the heart, muscular twitchings, general nervousness, and diarrhœa.

Pure caffeine is quoted by many wholesale druggists at about 14s. per lb., but it is very doubtful whether it is a genuine extract from coffee. Ordinary coffee contains about 1 per cent, Java 4·25 per cent., and Martinique 6·25 of caffeine. America is the greatest consumer of caffeine, it being used there in one or two important specialities.

Cagliari Paste.—This is of various shapes, similar to maccaroni, vermicelli, etc., Cagliari being the name of a province, and also the capital of Sardinia, celebrated for its hard, dry wheat.

Caju-nuts.—See *Cashew-nuts.*

Cake Powder.—See the *Easteleine Company's* adv., near end of book.

Cakes. —See *Slab Cakes.*

Calabar Beans. — The seeds of *Physostigma venenosum*, imported from the Calabar coast of West Africa. These ordeal beans are highly poisonous.

Calabash. —F. *Calebasse;* Port. and Sp. *Calabaza.*

These gourds are of two kinds, viz., the long, or Ceylon, and the round. The East African Calabash is full of bright orange-coloured seeds, about the size of a shilling when ripe, and at that time covered with a thick glutinous coat. They are excellent vegetables

when young, and when dried are utilised as basins, baskets, and other vessels. In Spain they are commonly employed for carrying wine.

Calcavalla or **Calcavellos.**—Port. *Carcavellos.*

A highly-flavoured and sweet white wine from Portugal; also manufactured as a British wine in imitation of the above.

Calcium Soap. — A soap made either directly by saponifying fat with hydrate of lime, or by treating soluble soap with a solution of a salt of lime. Used chiefly in the manufacture of stearin wax.

Calcutta Howrah.—See *Chutneys.*

Calf Meal.—Various mixtures are made up under this name. The following have been prepared for many years by one of the largest spice houses:—(1) 46lbs. ground lentils, 40lbs. fine locust meal, 10lbs. linseed meal, 6lbs. ground liquorice, 2lbs. table salt. Somtimes a little turmeric is added to impart a yellow colour. All the ingredients must be finely ground and well mixed together. (2) 52lbs. fine locust meal, 28lbs. linseed meal, 28lbs. ground lentils, 2lbs. common salt, and 2lbs. ground fenugreek; total 112lbs.

Apply to Roger Errington, Victoria Mills, Sunderland.

Gardner's patent "Rapid" Sifter and Mixer, freely used for calf meals. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Calves' Feet Jelly. — (See also *Table Jellies.*)—Used to be made from calves' feet and flavoured with either Cognac, Madeira Wine, or Sherry, but seldom now except in private families. After calves' feet went out of use, neat's feet or cow heel, with parchment cuttings, calves' pates, etc., were used, but gelatine has since come into vogue, and is found very suitable for the purpose. Most of the Calves' Foot Jellies sold in bottles, even when prepared by first-class makers, are now made from gelatine. For a common jelly, soak one pound of gelatine for an hour in a gallon of water and then bring to a boil on a slow fire and strain.

Californian Fruits. — The most popular importations comprise Apricots, Plums, Greengages, Peaches, Pears, etc., which are graded as Extras, and Standard No. 1 or No. 2, according to quality. They arrive in 2½ to 3lb. tins, packed in cases of two dozen. An increasing quantity of evaporated or dried fruits now come from California, and there is every prospect of these becoming highly popular throughout the United Kingdom. Fresh Peaches and Apricots also come occasionally packed in light airy cases, but they do not keep good always. California also is noted for its oranges, the yield for the last season, December to June, 1900, being about 4½ million boxes. The orange industry is mainly confined to the southermost counties of the State, and only a small number reach England.

Californian Wines. — Wine production in California may really be said to be in its infancy, for, although a few inferior sorts have been made there over a hundred years, they were produced from the Old Mission grapes which were originally introduced by a body of Franciscan friars from Mexico, and these Mission grapes are heavy bearers, but make very poor wine. It was only in 1880 that the business began in earnest, when some 200,000 grape cuttings and rooted vines of the finest varieties were selected in Europe, Asia, Persia, and Egypt, and distributed throughout the State, the most noted sorts being the Hungarian *Zinfandel*, the French *Folle Blanche*, *Semillon*, *Cabernet Sauvignon*, *Cabernot Franc*, *Petit Pinot*, and the best of the Bordeaux, as well as the German *Riesling* or *Hock* vines.

The Californian soil and climate being perfect and reliable for vine growing—in fact, it has been proved that the soil in several parts of the State is quite equal to that of France, while the climate is far more reliable—they have succeeded beyond expectation. Instead

of an annual crop of some 5,000 up to 1880, the yield in 1893 was about twenty million gallons, and of excellent quality. In 1897 it was nearly 26 million gallons, viz., in Sonoma 9, Santa Clara 7¾, Napa 4½, and other counties 4½ million gallons. About one-third of the product is now consumed in California, and the rest either sent into the other States, New Orleans, New York, etc., or exported. Increasing quantities are now finding their way to England, many persons preferring them for their simple purity and wholesomeness. The best made up to the present time are the natural dry red and white varieties, such as those of the Claret, Burgundy, Sauterne, Hock, and Chablis types, which are grown on the coast range extending north and south of San Francisco.

Although made from the same varieties of grapes as in Europe, the wines are somewhat different. For instance, the White wines made from Riesling grapes, although resembling in many respects the German Hocks, have much less acidity and more body.

This is evidently because the grapes ripen in California, whereas in Germany they scarcely ever do so.

Sauterne types in California, very clear and soft, are chiefly made from the Semillon and Sauvignon-Blanc grapes, but have not the excessive sweetness of French Sauternes.

The counties of Los Angeles and Fresno, being warmer, are particularly suitable for Sherry, Port, and other sweet sorts. In car load lots, these wines, of good quality, can be bought at 1/6 to 1/8 per gallon.

There is obviously a great future for wine production in the "Golden State," and so far there have been no signs of phylloxera.

Calisayine Bitters. — (See also *Liqueurs* and *Medicated Wines.*)—A tonic liqueur or "bitters" prepared from Bolivian bark (*Cinchona calisaya*).

Calisaya (the native name for the bark in Peru and Bolivia) is, however, a rather dangerous and disguised intoxicant, and, although taken by men, women, and children as a tonic, constant indulgence is said to result in paresis, cirrhosis of the liver, diabetes, and death.

Calla-roots.—These are a new kind of American vegetable resembling potatoes, but longer, and consist of the roots of the *calla* lily. The interior is also a little more viscid than the ordinary Irish tuber, but when cut up there is very little difference. They are already grown extensively for market in the swampy lands of Florida and other parts of the United States, where flooded lands yield enormous crops. They reproduce themselves by the multiplication of their bulbs underground.

It is said the Egyptians have cultivated for centuries similar crops during the season of the Nile overflow, and that calla lily bulbs are a common vegetable also in Japanese markets, but it is only recently that the Western world has become alive to their palatableness and prolificness as an agricultural industry.

Callibogus.—An intoxicating drink used by fishermen of Newfoundland, Labrador, and the Gulf of St. Lawrence, consisting of a mixture of spruce, beer, and spirits.

Callipash and **Callipee.** — See *Turtle Meat.*

Cambric Tea. — A conventional name for a mixture of hot milk and water, given to children.

Cambridge Sausages (Royal).—These once famous sausages seem to have lost much of their celebrity. They were made formerly of two parts of meat to one part of bread, but now this is reversed. The old recipe was:—Chop well equal parts of lean pork and veal, say 1lb. of each, to this add 1lb. of fat, part pork and part veal, chop and beat well with a hard beater. Allow 1lb. of bread crumbs, a little parsley, thyme, two heads of leeks, or a little garlic or shalot, chopped very fine, 1 oz. of sage leaves, chopped very small, salt, pepper, and nutmeg. For each pound allow one egg, the yolk and white separately; beat both well; mix in the yolks and

enough of the whites to moisten the bread. Turn the skins inside out, stretch them on a stick, wash, and scrape them in several waters. When perfectly clean take them off the sticks, and soak in salt and water for two or three hours before filling.

A modern method:—To every 20lbs. of lean meat there is usually added 12lbs. of fat and 10lbs. ground rice, which has been boiled a quarter of an hour in a bag. The rice and meat are then chopped up together with the seasoning till quite fine. A good seasoning powder is made by mixing 4lbs. salt, 1½lbs. white pepper, 3 ozs. each of sage, nutmeg, and ginger, 1½ ozs. of mace, and ½ oz. cloves. About ½ oz. of seasoning is used for each pound of meat. Bread is sometimes used instead of rice, but rice keeps good the longest. *Sausage machines* save much time, noise, and labour in chopping.

Cambridgeshire Cheese.—A noted kind of soft or cream cheese.

Camel Corn.—See *Chick Peas.*

Camembert Cheese.—A small, flat, soft cheese of circular shape and pale yellow colour with a dark rind, originally made from whole or partially-skimmed milk, around the village of Camembert, in Normandy, France. Very fine, sweet, and delicate in flavour, and commands a high price at all seasons, but is very soft and soon perishes. They are now imitated in nearly every part of France, and also abroad, so that not one hundredth part of the cheese sold under that name are produced at Camembert; but there is a weekly market at Alencon, where the genuine are to be had.

Composition:—Water, 51·30; casein and albumen, 19·00; fat, 21·50; milk and sugar, 3·50; ash, 4·70. About £150,000 worth is made yearly, and it is considered one of the best soft cheeses made. It is ripe in about four weeks, but the flavour depends on the successful growth on the outside of the cheese of a fine pilose mould, which is first white, and then blue, the mycelium of which penetrates into the interior of the cheese, and causes a change in its body equivalent to ripening.

Camembert is undoubtedly one of the best and most saleable of the soft and fancy cheeses which have come so much into vogue during the last few years. About five gallons of good new milk will make a dozen cheeses, the curd being made at twice, half the milk being set in the morning and the other half in the evening. Temperature of milk 80° to 84° F. A sufficiency of rennet is used to cause a fairly firm coagulation in three hours—the rennet being exactly measured with a cubic centimetre pipette. Example—Take 25lbs. of warm, fresh morning milk, make it 82°, and set the milk in wooden tubs so as to conserve the heat. Add two cubic centimetres of Hansen's rennet, mixed with a little water, and stir occasionally during the first half hour. In three hours the curd will be ready to ladle out into the moulds, which are perforated tin cylinders five inches high and as many broad. These moulds are placed on straw mats, which assist drainage, and give the cheese a nice surface. In *ladling* out, do not break or mash the curd, or loss of fat will result.

In the evening repeat the process with fresh milk, except that perhaps a little more rennet will be necessary, the evening's milk being richer. By the time the evening's curd is ready the other will have sunk, and left room for it to be filled in, having first broken the top of the morning's curd so as to let the two curds join. By the evening of the second day the cheeses will have settled, and be firm enough to turn out on to fresh mats, where they are slightly salted on the upper surface, and left for twelve hours, being then turned and salted on the other surface and sides, and the moulds removed. The cheeses remain in the making-room four days, when they are placed on shelves covered with straw, in a room where they can get currents of air so as to ensure partial drying. They here remain a week, and become covered with a fine white fungus or mould peculiar to Camembert, and then a blue mould.

They are then ready to be removed to the cellar or cave for perfect ripening. This cellar should be cool (about 50° F.) and dark, with very little ventilation and a fairly moist air, and provided with shelves covered with straw, on which the cheeses are placed. Turning is done each day, and in the course of three or four weeks they will be ripe, which condition is known by their assuming a reddish tint, and the body of the cheese on pressing being soft and yielding. A ripe Camembert weighs about 11 ozs. They are sent to market in light, wooden, round boxes, one cheese in each box, or sometimes in packages of six, wrapped in straw, which keeps the cheeses in shape, also preventing dryness. They keep well in the original boxes. If they should get soft, they will harden on being exposed to the air, by removing the cover from the box and putting them in a cool place. If too hard, they can be made soft by putting them under a glass cover. If the wrappers become soiled, re-wrap them.

Camomile.—See *Chamomile.*

Camphor or **Camphire.** — F. *Camphre;* Du. and Sw. *Kamfer;* Da. and G. *Kampfer;* It. *Canfora;* Port. *Alcamphor;* Rus. *Kamfora;* Sp. *Alcanfor.*

The gum, or concrete volatile oil, of several kinds of laurel and bay trees of Eastern Asia, especially the *Cinnamomum Camphora*, or Camphor laurel, common in Formosa, Japan, India, and China, whence it mostly comes to Europe in small crumbly masses (like coarse raw sugar) or "Bells," and packed in chests, drums, and casks. The root, bark, leaves, and berries of the tree smell strongly of camphor. The wood is cut up into small pieces, 1½ to 2½ inches in size, which are boiled in water and steamed over a slow fire. The steam rises and wets the *straw lid* of the kettle, and when cool the crude camphor is found in the straw in small sand-like grains. Sometimes a bamboo pipe conveys the steam to vessels filled with cold water. After being refined by subliming it from quicklime in iron vessels it condenses, and is generally sold in thin hollow cakes, quite white, but if exposed to the air it totally evaporates. In the provinces of Tosa, Hiuga, and Satsuma, in the South of Japan, there are immense groves of these camphor trees, huge evergreens of singularly symmetrical proportions, and not unlike lindens, many of them owned by the Japanese Government, the wood being very desirable for ship-building. These gigantic trees are very pretty; about as hardy as citrus trees, vigorous, and long-lived. Some are 10 to 12, or even 15 feet in diameter, and upwards of 300 years old, and the law provides that for every tree cut down a young tree shall be planted in its stead. The roots contain a much larger proportion of camphor than the trees. The camphor and camphor oil are distilled by peasants who are very poor, and employ only the rudest machinery. The wood is boiled five or six times, and 320lbs. of wood usually yields about 6lbs. crude camphor. This camphor is exported from Tamsui in matted wooden tubs, measuring 6½ cubic feet and containing 133⅓lbs. each. The adulteration is generally water, sometimes oil. The quality known as *good old dry* is the best by reason of its greater purity, pinkish colour, and bold grain. The Japanese product fetches 2½ to 10 per cent. higher prices than the Formosan.

Very little information can be obtained from the Japanese regarding its manufacture, and the only foreigner known to have visited the camphor districts declined to give any details about it. The "independent" savages of that region, said to be of Malay origin, will only trade with the "Hakkas," or Chinese immigrants, and will not permit any others to approach their mountain fastnesses. Two or three American companies have, however, lately been organised for refining camphor in Japan. Although the camphor laurel is very common in China, very little is manufactured there. In the island of Formosa, where camphor has recently been made a Government monopoly

here are several immensely wooded districts, and there is little fear of the supply being soon exhausted. The inhabitants, however, are aboriginal barbarians, and apt to make dangerous outbreaks. A large quantity of Formosa camphor and some from Amoy comes to England by way of Hong Kong, but it contains a great deal of oil and moisture, and cannot be refined to the proper hardness without adding Japan camphor to it. To make it fit for exportation requires much work, diligence, and experience. The crude article is brought by the natives to the market in very rude wooden tubs. Each tub is carefully sampled, vertically and diagonally, and the samples are tested by fire, and sometimes by alcohol. The rest is easy, and consists in weighing, cutting, mixing, and packing for shipment.

In Formosa no trees under 50 years old are used, and in Japan none under a century.

Camphor is not now much used in making smokeless powder, on account of certain practical disadvantages discovered. It is, however, used in continually increasing quantities for the conversion of collodion cotton into celluloid, which is applied to the manufacture of imitation ivory, tortoise-shell, horn, and a great variety of purposes. As an adulterant, a substitution of Borneo is sometimes made. This latter, a stearoptene, known as *Borneol*, $C_{10}H_{18}O$, is imported in liquid form, but is a product of *Dryobalonops aromatica*, and so is the hard camphor of Sumatra. Camphor is very bad for painting other goods. Imported in the form of tablets and bells in casks of about 5 cwts. each. The price is now four times what it was 20 years ago. Annual imports about 100 tons of refined and 600 tons of unrefined.

Camphor Balls, Squares or **Cakes** —Also called *Chap Balls*, *Chilblain Balls*, etc.

These are mainly used to anoint the hands after washing, to prevent "chapping" and chilblains, or as a scent. How prepared: (1) 3 dr. white wax, 3 dr. spermaceti, ½ oz. almond or olive oil, and 2 dr. powdered camphor. Colour if desired with alkanet root and stir till partly cold. (2) 1 oz. lard, 1 oz. white wax, and 1 dr. of camphor.

Camphor Soap. — Formulæ: — Soap 1,500 parts, oil 40, essence of lavender 5, camphor 60, cocoanut oil 1,000, caustic soda at 40° B 500. When saponification is complete add alcohol 100, water 50, and camphor 75.

Camphor Tea.—A solution made by pouring boiling water on a lump of camphor.

Camphorated Chalk.—Used chiefly as a tooth-powder, and prepared by mixing 6, 10, or 15 parts of precipitated chalk with one part of powdered camphor. The lump camphor should first be broken up, a small quantity of rectified spirit added, then reduced to a fine powder, and lastly passed through a fine sieve. Prepared chalk often used in lieu of the precipitated. It is less clean and velvety, but cleans the teeth better.

Camphorated Oil. — According to the Brit. Pharm., this should contain not less than 21 per cent. of camphor and 71 per cent. of pure olive oil; or 1 oz. of camphor dissolved in 4 fluid ounces of olive oil. Camphor evaporates very rapidly, and if exposed, or the bottles be opened frequently, the retailer may be fined for selling it under its proper strength. Olive oil should be used in preparing it and not cotton seed oil, the latter being very inferior in its healing properties. Liquid paraffin is, however, an admirable solvent for camphor, and the solution has the advantage over the usual camphorated oil of becoming perfectly limpid with a little heat. Nevertheless, if the camphorated oil be found deficient in camphor or olive oil, the seller is finable. It should also be remembered that in store bottles the camphor is liable to settle, and so leave the upper stratum of oil deficient.

Camp Ketchup. — How to make: —Heat to boiling point ½ gallon old beer, 1 quart sherry, ¼lb. anchovies, then add ¼lb. crushed shalots, and ½ oz. each of ground ginger, nutmeg,

mace, and pepper; put into a stone jar and shake it once every day for a fortnight, then allow it to settle, and bottle.

Camwal. — The initials of the Chemists' Aerated Mineral Water Association, Limited, which professes to supply chemists only who are shareholders.

The *Idris Co.* is another limited concern professedly supplying only chemists, hotels, clubs, etc., at wholesale prices.

Canadian Balsam. — A kind of turpentine or liquid oleo-resin obtained from *Pinus balsamea*, used for mounting microscopical objects.

Canadian Produce. — The staple foods received into this country from Canada are Cereals, such as wheat, barley, oats, flour, etc.; animals (living), dressed meats, cheese, butter, eggs, fish, fruit, lard, condensed milk, potatoes, poultry, and game; but of the total annual imports of such products from all countries (about £120,000,000) Canada, so far, sends only about 7 per cent., whereas she can easily supply 30 or 40 per cent.

The Canadian climate, fertile soil, and her intelligent, cleanly, and industrious people are most favourably adapted for yielding the very highest qualities.

Products from that pure and healthy northern atmosphere seem to have better keeping qualities, richer flavour, and a higher percentage of nutritiveness than those grown further to the south, so that their importations may be expected to increase rapidly.

The wheat, flour, and cheese are not injured in quality by being carried at the ordinary temperatures of the atmosphere. Indeed, Canadian No. 1 hard wheat and flour from the sun-kissed prairies of Manitoba and the North West are unsurpassed by those from any other part of the globe. Butter, dressed meats, fruits, eggs, poultry, and a few other articles require to be carried in cold storage to protect them; but to help the Canadian farmers and settlers to obtain a foremost place in the British markets, the Canadian Government has provided what is practically a complete chain of cold storage service from the producer along the railways and steam ships to the ports of Great Britain. It has arranged and subsidised not only trains and ships, but also cold storage buildings at the ports of export, to be maintained until the trade can take care of itself. It has also encouraged creamery owners to erect cold storage rooms, by allowing a bonus of £20 to each of those used and kept at a satisfactory temperature.

Canadian Apples.—Are referred to under *American Apples*. The grading, packing, and handling in Canada is capable of improvement. There seems to be a difference of opinion there in defining standards—Ontario, for instance, contending for size as indicative of No. 1 A; while Nova Scotia, whose apples are among the best will not agree. There is also too much dishonest packing, *i.e.*, "topping," or placing the finest apples at the top and the inferior below. The Nova Scotian Standard for apple-barrels is 150 quarts, dry measure.

Canadian Bacon. — The development of the pork-packing industry bids fair to surpass that of the United States. The fact that Canada's exportation of bacon, hams, and lard has grown from $870,313 in 1890 to $5,860,584 in 1897 is sufficient of itself to attract consideration. There is now a regular and active demand on the British markets for this superior class of products. The chief factories are at Toronto, Hamilton, Bowmanville, Palmerston, Brockville, and other points of Ontario, Quebec, Winnipeg, and Vancouver, but over three-fourths of the exports are from Toronto. The so-called pea-fed bacon and hams from the Ontario packing houses are now recognised as fully equal, if not superior, to the best Danish, but the term "pea-fed" does not necessarily mean that the hogs were fed on pea-meal.

Canadian Butter.—The Dominion Government, moreover, undertakes the

management of some creameries in the north-west territories, making and marketing the butter, etc., and lends to settlers in these districts, who have formed joint-stock companies, sums of money sufficient to provide the necessary machinery.

Canadian butter comes to England either in boxes or 70lb. tubs, and is mostly made between November and April from "stall-fed" cows, the grass milk being preferable for cheese-making.

The expansion in the Canadian export butter trade was even more remarkable this year (1899) than last, the increase in quantity being almost 50 per cent., while the increased returns to the producer are also nearly 25 per cent. more than they were last year. In round figures, 451,050 packages of Canadian butter were shipped to England in 1899, and the price has averaged $1 per package more than in 1898. Taking this as the basis, the revenue from butter was $5,998,000, an increase of $2,000,000 odd, as against a gain last year of only $610,000. This is certainly a most remarkable showing. The range each month throughout the year was higher than 1898. The highest price of the season was paid in September, when 24c was realised. One has to go back to the year 1894 before coming across a similar figure, and then it was not in the fall, but on stock that had been carried through the winter months, which, of course, made its cost all the more. The low level was during June and July, when 17½c. was the price. In May the price averaged 1½c. more than in May, 1898, in June 1c., in July 1¾c., and in August and September 3c. per pound above the same months in 1898. In October the difference was only 1½c., and in November it had fallen to 1c. per pound.

Bristol still continued to be the leading customer, but Liverpool this season took second place from London, as destination for Canadian butter. The ports stand in the following order:—Bristol, 158,210 packages; Liverpool, 105,864; London, 105,135; Glasgow, 13,847; Newcastle, 7,400; Aberdeen, 741; Leith, 406; Antwerp, 204; Manchester, 29,242—total, 451,050 packages.

The laws of Canada prohibit the manufacture and sale of oleo-margarine, butterine, and imitation or 'filled' cheese (margarine-cheese).

Canadian Cheese.—Not less than 60 per cent. of the whole of the cheese imported into this country now comes from Canadian ports; but it is said some of it is really made in New York State and Wisconsin. "French" grades are also often rebranded and sold as fine grades of Canadian, masquerading as "*Perth Gems.*" Sometimes American cheese, sent forward unbranded, is afterwards branded "*Canadian*" or "*Ingersoll*," with false names of shippers or factory, so that the branders cannot be traced.

There has been much legislation to uphold the standard of Canadian goods. In 1893 an Act was passed preventing the making of filled cheese, prohibiting, under pain of a fine, the fraudulent branding of the word "Canada" on cheese not made in the Dominion, and providing that the name of the country from which cheese came into Canada should be plainly marked on the package. In 1897 an Act was passed to provide for the registration of cheese factories and creameries and make the branding of the word "Canada" or "Canadian" on all cheese and butter intended for export compulsory. The branding of the date of manufacture was not rendered compulsory, but any misrepresentation on the subject by means of marking packages was rendered punishable. The registration of factories and creameries is provided for, and the product of each can, in consequence, be identified. Still, August cheese is often sold as September make.

These things destroy confidence in the article, as also does the practice of selling Autumn-made cheese, but delivering earlier makes of non-keeping quality out of cold storage.

Canadian cheese is nearly all shipped from Montreal, where there are about half-a-dozen large merchants, or agents, of Europeans firms. These agents have

other sub-agents buying for them in Ontario and Quebec. Most of the real Canadian cheese is made in Ontario. The best is made in Perth, and the best autumn makes have lately been beating our best English in price and quality.

There are 1,123 cheese factories in Ontario. About 75 per cent. of these are east of Toronto. The following counties have the greatest numbers:— Hastings, 96; Frontenac, 72; Leeds, 65; Prescott, 63; Dundas, 55; Carleton, 53; Glengarry, 48; Oxford, 45; Russell, 44; Lanark, 43; Stormont, 43; Northumberland, 43; Grenville, 40; Middlesex, 39.

The curing occupies only about three months, and the manufacture is carried on from April till November, but the quality produced during these two months and the intervening winter season are from "fodder-fed" cattle, and so much inferior to the summer and autumn grass makes, that factory-men are discontinuing their manufacture.

The freight and other transportation charges to English ports only add about 6 per cent. to the cost. The boxes, however, are often badly made, and of green, instead of well-seasoned, wood. The cheese-making industry in Prince Edward Island is showing remarkable development, and large shipments are being made to England from Charlottetown.

Canadian Eggs. — These are of uniformly large size, carefully selected, and arrive in good condition, as to freshness, cleanness, fulness, and central position of the yolk. The Canadian egg case, with its cardboard compartments, is greatly preferred by many to the egg cases from other countries, and the exports from Canada nearly all come to Great Britain. In 1896 we received over 5½ million dozens and in 1898 over 10¼ million dozens.

Canadian Poultry is also an important branch of business. (See *Turkeys.*)

Special Importers from Canada:— W. A. McKnight (cheese, butter, and eggs), 24 Mathew Street, Liverpool; R. Rutherford & Co. (bacon and butter), 3 Hood Street, Liverpool.

Canadian Tea. — A decoction made from the leaves of *Gaultheria procumbens.* (See also *Tea Berry* or *Mountain Tea.*)

Cananga Oil. — This is the name applied to a perfumery oil resembling that of Ylang Ylang. It is distilled from the flowers of *Cananga odorata*, indigenous to Burmah, and cultivated in many parts of the Eastern Archipelago. The oil is largely exported from Java, and the best from Manila. It has a specific gravity of from 0·910 to 0·920. Price about 18/- per lb.

Canary-seed. — Da. *Canarifröe;* Du. *Kanaryzaad;* F. *Alpiste* or *Grain de Canari;* G. *Kanariensamen;* It. *Sema di Canario;* Sp. *Alpiste.*

The small white or reddish seed of canary grass, *Phalaris canariensis*, a native of the Canary Islands, used chiefly for feeding birds, but occasionally employed in some countries in the preparation of human foods. Large quantities are imported into England from Holland and Germany. English canary-seed is mostly grown in Kent and Isle of Thanet. A quarter of English seed weighs 448lbs., foreign about 464lbs. Some 500 or 600 tons of canary-seed are sold in England yearly, and entirely for the purpose of feeding cage-birds. New crop due about 1st September.

Special Firms.—Hedley, Gamble, & Crosfield (cleaners), Circus Street, Liverpool; Morris & Jones (merchants), 13, 15, and 17 Sir Thomas Street, Liverpool.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

Canary Tea. — Obtained from the plant *Sida canariensis.*

Canary Wines. — These comprise the cheap Sack and Port wines made in the Canary Isles (Spanish). The favourite kind is *Teneriffe* or *Vidonia*, a dry wine of good body, produced at the vineyards around Las Palmas,

Grand Canary. Some say the best vineyards are at Orotava, S. Ursula, Ycod de los Vinos, Buenavista, and Valle de Guerra.

Malvoisie is made from a very sweet kind of grape called *Cabosa*, and special to the Islands of Canary and Madeira.

Canary *Sack* is a white variety of full flavour, almost similar to Madeira (Portuguese), and like Canary Port is usually retailed in England at about 1/- a bottle.

The Malmsey of Teneriffe is also an excellent product, but rather acid.

Candied Fruits.—See *Crystallised Fruits.*

Candied Peels.—(See also *Citrons, Lemon Peel*, etc.)—Candied peels are in England generally prepared as follows:—The Bitter, Seville, or Bigarade oranges, the lemons or the citrons, are cut in two halves and each pressed by hand flat side down on the top of a revolving knob of wood, a trifle smaller than the fruit, to clear out the pulp, pips, and ligatures, which fall into a trough. This pulp is largely used in Marmalade manufacture. The peels, after being soaked some few days, weeks, or months in salt water, are washed in clear water, then boiled in water until soft and until the salt is got out. They are afterwards boiled several times in syrups of sugar. This last process occupies about a week, for the peel must be boiled in very thin syrup, then got to absorb thicker solutions, until the peel assumes a swollen transparency. They are finally half filled with thick syrup, and dried at a gentle heat on trays.

Leghorn is the chief seat of the industry in Italy, citrons, oranges, lemons, etc., being received for this purpose from Corsica, Sicily, Calabria, and other southern provinces of Italy, also from Tunis, Tripoli, and even Morocco. The sugar is imported from Egypt. The wood for the boxes in which the peel is packed goes from Trieste. The fruits are sent halved and packed in hogsheads in fairly strong brine, so as to ensure thorough preservation of the rind, by an equal saturation of the interior, as well as exterior, face.

Women with the fore-finger and thumb quickly gouge out the insides, and throwing this aside place the rind unbroken in a vessel alongside them.

The rind is next carried to large casks filled with fresh cold water, in which it is immersed for two or three days to rid it of the salt it has absorbed.

The rinds are then boiled one or two hours in a large copper cauldron to make them tender, also to ensure the extraction of any remaining salt.

The fruit next undergoes a saturation for about eight days in large jars with syrups of various strengths. This causes the slight fermentation desired. After this the peel is boiled and stirred for about an hour in still stronger syrup, of a density of 40 degrees, in large copper vessels over a slow coke fire. The contents are then poured over a large wooden trough, over which is coarse open wire netting. The peel is distributed over the surface of the netting, so that the syrup, now thick as treacle, may drain into the trough below. The peel having now taken up as much sugar as necessary, a quantity of crystallised sugar is dissolved in a little water, and into this the now dried peel is immersed, and the whole again boiled over a slow fire, until the little water is driven off; and the sugar upon cooling will form its natural crystals over the surface of the fruit. The peel after being finally dried on the wire netting is now complete and ready for packing in 7lb. boxes. Thus the great bulk of candied peels have until lately been prepared in Italy—particularly at Leghorn, Palermo, and Messina; but there appears no reason why they should not be wholly manufactured in this country, where sugar is cheaper and mechanical enterprise greater. Indeed, many of our manufacturing confectioners and jam-makers now cure and turn out big lots, thousands of hogsheads of fruit in brine coming from Bastia and other ports to England for that purpose. It seems, however, that during the last year or two an emasculated article has found its

way into the shops. It is known in the trade as *Candied Skins*, from which all or most of the essential oil has been extracted before candying. It is only 2/- or 3/- per cwt. lower in price than the genuine, and even looks brighter and more attractive, but it is really very deficient in flavour, and may be detected by the taste.

For the genuine article, apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Candied Sugar.—See *Dutch Candy*.

Candies.—An American term for Sweets or Boiled Sugars.

Candle-nuts.—The kernels of the candle-nut tree, *Aleurites moluccana*, which grows on most of the Pacific Islands, also in Central America. These kernels are very rich in oil or fat, and the natives commonly thread several of them on the mid-rib of a palm leaf or reed or stick of wood. When lighted they become fair substitutes for candles. They are so used by the San Blas Indians in Central America, and a child usually has the duty of knocking off each nut as it burns out. In Tahiti and Fiji the tree is called *Futui*, and *Doodoe* is its title in Pitcairn's Island. These nuts are similary used as candles in the Hawaiian Islands.

Candles. — Du. *Kaarzen;* F. *Bougies* or *Chandelles;* G. *Lichteren* or *Kerzen;* It. *Candeles;* Sp. *Bujias;* Port. *Velas;* W. *Canwyllaw*. (See also *Dip*, *Mould*, and *Paraffin Candles*, *Rushlights*, *Ozokerit*, etc.)

If ever there was a phase that distinctly marks the progress of man in civilisation, it is to be found in the methods which he has adopted from time to time for producing artificial light. He began with the rude torch, which served as a means of illumination as far back as we can trace in human history, and which, even in our day, is the accompaniment not only of the war dance of the veriest savages, but of the rejoicings, by processions and other celebrations, of the most highly cultivated youths of the universities.

Nor is the series just commenced as yet completed, for notwithstanding that the force of electricity has been pressed into our service as a substitute for sunlight, that very light itself has already been stored up on a small scale to produce a faint glimmer sufficient to distinguish printed characters for the hour of night in the sleeping apartment during the absence of the great luminary himself.

In the Isle of Man and a few other places there are districts where one of the oldest customs of people making their own candles still survives. The ironmongers sell the necessary utensil—a long candle-shaped tin tube, with a handle for holding. A home-made wick, constructed out of old fishing nets unravelled, or almost anything else, is passed through this tube, and all the fatty refuse that is not good enough for the pig is melted down and poured into it. Once cool, the candle is drawn out and its manufacturer lives light free.

Many brands of candles under a many different names have been brought into the market, but most of them vary only very little in composition. They are made from either tallow, wax, or spermaceti, or a mixture of these substances. Their value depends upon their clear burning, high melting point and light-giving properties, as well as on their handsome appearance, which in all cases should be as white and transparent as possible.

Exhaustive experiments have shown that the chief factors affecting the light which a candle gives are:—The number and size of the threads in the wick, the closeness of the plaiting of the strands, the pull on each strand during plaiting, the previous cleaning of the cotton used, the treatment of the wick by the manufacturer, and the extent to which the wick is stretched when set in the candle mould by the workman.

Various other conditions also affect the amount of light a candle affords, such as the length of time it has been burning, whether the "cup" of the candle is dry or contains melted sperm, the

ughness or smoothness of the wick, ie curvature of the wick, etc.

"Paraffin" candles are probably sold ow more extensively than any other.

Candles are usually either *dipped* or *oulded*. The former are generally mposed of coarser tallow.

"Mould" candles were first intro-uced by the Sieur De Brez, in the 15th ntury. The great faults of tallow ndles are that they "smoke," gutter," give off a bad smell, and they e easily bent with warmth. If we press llow, a liquid oil exudes, called *olein*, id it is this liquid olein which renders llow so soft, and which, by melting oner than the harder stearin, causes e candle to gutter and form columns slag wax.

Recent improvements in candle-aking have, however, been introduced, hich consist in not employing the hole of the fatty or oily substances, it in decomposing them and then using ily the *stearine* of the fat and the *almatine* of the oil.

Candles are, therefore, now chiefly mposed of stearic acid. It has a gher melting point than tallow, mely, 150° F, and the gases produced the destructive distillation of stearic id in the flame of the candle burn th a brighter flame than those pro-uced from tallow. The light of the me is due to the incandescence of rbon particles liberated by the decom-osition of the various hydrocarbons esent.

Wax cannot be formed into candles melting it and then running it into oulds, because of the tenacity with hich it adheres to the mould, and its eat contraction on cooling; but the cks properly cut and twisted are sus-nded by a ring over a cauldron of uid wax, which is poured on the tops the wicks until a sufficient thickness obtained, when the candles, still hot, e placed on a smooth walnut table, pt constantly wet, and rolled upon it means of a flat piece of boxwood or lled between marble slabs.

The large candles used in Romish churches are merely plates of wax bent round a wick and then rolled.

Candles improve by keeping a few months. Those made in winter are the best. The most economical, as well as the most convenient, plan is to purchase them by the box, keeping them always in a cool dry place.

The duty on candles was repealed in 1831 by Acts 1 and 2 William IV., cap. 19. The penalty for evasion of the duty was very severe.

Candle-power, in comparison with the electric light and the standard of light referred to in the phrase "*sixteen-candle gas*," are based on the average light afforded by an average sperm candle, burning at the rate of 120 gr. an hour.

Candle-wicks are usually composed of spun cotton plaited together, and the wick tends to bend naturally.

The wicks were a great source of trouble formerly, because the cotton wicks showed a great tendency to stand up above the body of the candle till they came in contact with the air.

One method to obviate the long wicks was to soak them in solution of nitre, so that they provided their own oxygen, but if the solution were slightly too strong, the wick disappeared in the fat, and the flame was extinguished.

Another method, invented by Messrs. Palmer, of London, was to have a thin bismuth wire running through the tip of the wick to bend and come in contact with the air.

For stearin and paraffin candles the wick is plaited over a braiding machine and dipped in a solution of boracic acid before using. It thus twists out of the flame, and is completely burnt away, so that snuffing is not required.

Coloured Candles.—Pigments have hitherto been used for colouring candles —such as vermilion, ultramarine, etc., in a fine state of division; but a better effect is now obtained by the use of oil-soluble aniline colours. These are obtainable in the leading shades of blue, green, yellow, red, and brown.

Rosin Candles, or Torches, used to be very common in France, but are now only used in Brittany. The method of

manufacture is the same as that adopted by the ancient Gauls. Hempen fibres are steeped in molten rosin, and then rolled between two hard bodies to give them a somewhat cylindrical form.

Cane Sugar. — Port. *Azucar de Canha;* Sp. *Azucar de Caña.* (See also *Sugar.*)

Cane sugar is made from the saccharine juice contained in the slender stems of the sugar cane, *arundo sacharifera,* a perennial plant, or gigantic grass, very sensitive to cold, and only thrives in regions bordering on the tropics, where there is little or no frost. The plant requires cultivating, and is not known wild in any part of the world.

It originally came from China; was cultivated in Persia A.D. 500, Egypt 750, and was produced in Sicily, 1148; in Madeira, 1419; in the West Indies, 1510; in Barbadoes, 1641. It is now cultivated in nearly all warm countries, and there are many descriptions grown. Large quantities are raised in Cuba by cheap coolie and Chinese labour, in the north-east of Java, where the population is very dense and labour cheap, also Peru and in Brazil. The latter country receiving most of her imported merchandise from England, the ships conveniently bring back sugar as return cargo, so that most of the Brazilian sugar comes to Europe. Most of the Cuban sugar goes to the United States.

The Cuban sugar houses, in regard to capacity, are really in advance of those of any other country. Very many can grind 1,000 tons of cane in 24 hours and some can do more than this.

There are in France and Belgium, known as *Usines Centrales,* factories where the juice is conveyed by a system of pipes from small juice stations to a central establishment, which equal or excel the Cuban houses in capacity, but elsewhere there are none so large.

The cane grown in Java is almost black in colour, and is called "Cheriban." It attains a height of about 15 feet, and weighs 5 to 9lbs. Peru also exports large quantities of sugar, but the late war with Chili was very disastrous to the industry. Most of the plantations were destroyed by the Chilian army, buildings were demolished, the irrigation ditches were cut, and the labourers were driven into the mountains to escape conscription. In fact, Peru has scarcely yet recovered, but is again exporting a considerable amount of sugar.

Other cane sugar producing countries are Argentina, Guiana, Trinidad, Demerara, Martinique, and Barbadoes, Venezuela, Colombia, Ecuador, Mexico, Natal, Queensland, the United States of America, and Egypt. All these have enormous areas suitable for sugar growing.

Cane sugar is probably produced cheaper in Mexico than in any other country. There are two kinds of cane planted, one called the *Cana criolla,* or Creole cane, which is about ½ inch thick, of a light-green colour, with thin bark, short joints, and very sweet. The other, called *Cana pinta,* or painted cane, of a reddish colour, one inch in diameter, thick, with a tough bark and longer joints. The latter yields best and is the kind mostly planted, although the former gives a whiter and harder sugar.

Hitherto the cane has been reproduced under cultivation solely by buds and suckers. Three sorts of cane sugar are grown in India—the purple, the white and a variety of the white requiring large supply of water. The best soil for the purpose is tenacious, without being heavy, readily allowing excessive moisture to drain away. In some localities, where the ground is low, the beds where the cane is to be planted are raised 4 or 5 feet above the adjacent land. The soil should be sufficiently elevated to be entirely free from inundation; but not so high as to be deprived of moisture or to encourage *white ant.* The cane or stalk is a long, round, hard and knotted stem, growing in favourable situations from 6 to 20 feet high, with leaves from 1 to 6 feet in length, and having at the top a large panicle or cluster of long hairy flowers, but the cane is always reaped before it flowers

The average height of the cane is about 10 feet, with a diameter of 1 to 3 inches. The stem is hollow, but jointed, or marked, with the scars of fallen leaves, as in the bamboo. The Otaheite cane has been the popular kind grown in West Indies; but it is said the *Jamaican* is a marvellous cane, and stands dry weather better.

Sugar canes have, however, been propagated from time immemorial by cuttings, although during these last three or four years attempts have been made with the view of remedying the deadly fungus growths and other diseases of the cane to obtain fertile seed from the arrow or inflorescence for raising cane, but this is a very difficult and slow process.

A day or two before planting the cane the field is ploughed and lightly rolled. The set consists of the top joints of the canes cut off, tied in bundles of 40 to 50 each, which are kept moist and stored for the purpose from the previous harvests. When wanted for planting they are dressed and dipped in a liquid manure of cowdung, pressed mustard-seed, and water. They are then placed separately in the rich dry soil, and covered with leaves and grass to protect them from the heat. Ten or twelve days afterwards they are planted about 2 feet apart in rows, 3 or 4 feet distant from each other, in the fields, carefully watered and frequently hoed. In due time a tangled mass of thread-like roots strike into the soft earth, and eventually a bunch of 10 to 18 aerial canes spring up out of each root-stock, and assume various shades—some of green or purple, some variegated with beautiful stripes.

It is a rather curious fact that very few persons appear ever to have seen any mature sugar *seeds*. In botanical works the subject is often mentioned, but apparently only to reiterate the fact that the sugar cane so rarely matures its seeds that they have never been noticed. So rarely have these flowers been seen that some writers aver the cane bears none, but as often happens with plants cultivated to a large extent, and which are cut down before they flower, they after a time cease to flower. It is the same with rhubarb at Banbury, peppermint at Mitcham, and in numerous other instances.

In India the canes are planted in February, and in the following January are ready for harvesting. The cutting is then continued through January, February, and March.

It is one of the main drawbacks in cane cultivation that seed time and harvest fall together.

Some kinds, however, are ripe in 10 months, while others require 12 to 20 months. The canes are richest just before the plant begins to flower, and the lowest part of the cane yields the most sap, hence the desirability of cutting them as close to the ground as possible. The stump which remains develops into a fresh plant, and may last in this way several years. These new shoots are called "ratoons," and in some of the West Indian Islands (Dominica, for instance) the plantations go on ratooning in this way for 20 or 30 years, after being once planted. We receive our heaviest supplies of cane sugars from the East and West Indies, Mauritius, and Brazil.

In the West Indies a gang of negroes is turned into the field just before the canes begin to flower, armed with cutlasses, heavy iron blades a couple of feet long, fastened to a short wooden handle to give a firm grip. One blow severs the cane low down and a second cuts off the top. These cut canes are at once tied up in bundles with wisps of strong green strap-like leaves. The bundles are loaded into ox or mule drays, which crash along the lanes to the mill-yard, amid the shouts of the drivers and the cracking of whips, for the negro is nothing if not noisy.

The canes are next thoroughly crushed, and, after tempering the dirty-looking juice with lime and boiling down, it is run into flat, wooden troughs to cool. Here it sets into a dark-brown mass of wet crystals; by rapidly rotating these in "centrifugals" the molasses present is driven out, and a refined product is ready for the table.

Unfortunately, cane sugar raising in the West Indies seems doomed, unless the English Parliament speedily impose countervailing duties, which shall be equal to the bounties allowed to beet sugar exporters by foreign Governments.

There are several ways of extracting the sweet fluid from the ripe sugar cane:—

(1) The most general one is by pressing the long canes between the iron rollers of horizontal sugar mills, which squeeze out the juice, the refuse stalks, called "Megass" or "Bagasse," being afterwards used as fuel.

(2) The cane may be reduced by the use of raspers, or "defibrators," to a coarse pulp, and the juice expressed by powerful presses, at the rate of about 65 per cent. of the bulk.

(3) The canes may be macerated in steam or water, and the juice then extracted.

(4) A newer method is that of diffusion, in which the canes are cut in small pieces, and the sugar obtained by repeated washings with hot water. As the juice spoils very quickly, no more canes are cut each day than can be pressed or ground. By the first method the juice falls into a shallow trough, where it is "defecated" by adding to it hot milk of lime, or other similar substance. It is next concentrated by a quick boiling in copper pans, and after the grosser impurities rising to the top are removed as scum, a little milk of lime is added for the purpose of neutralising the vegetable acidity. The syrup is then run off into narrow wooden coolers, where the sugar concretes or partly crystallises, thus separating from the liquid which afterwards is known as molasses. The crude sugar is then put into hogsheads with holes in the bottom, through which for a month or six weeks more of the non-crystallisable fluid or molasses drain off into vats below, leaving the sugar in the state known as muscovado or *raw sugar*. Sometimes the molasses are separated more quickly by centrifugal force. A gallon of juice is usually obtained from about twenty ordinary canes, and yields about a pound of raw sugar, and in this state it mostly reaches the British refiner in Liverpool, London, Greenock, or elsewhere. The refiner generally commences by washing these raw sugars, mixing or dissolving them in hot water to which a little lime has been added, and then filtering first through cotton bags, and then through layers of bone black (animal charcoal) to discolour and clarify it. Up to a few years ago bullock's blood was used for precipitation of the raw sugar, but a more desirable substitute has been found, and this bone filtration leaves the liquid a water white. Being thus separated from all impurities, it is next boiled in vacuum pans with steam, and then whipped dry by a centrifugal machine into *Crystallised Sugar*, and thus separated from the unsolidified portion, or syrup, and may be then dealt with in two or three ways. (1) It may be further dried and passed through a bolting process which regulates or separates the different sized granules ready for market in bags, or (2) it may be put into moulds, conical or other shaped, to dry as Loaf Sugar, and the syrup which drips out is known as *Golden Syrup*. (3) The liquid intended for making into *Cube Sugar* after leaving the centrifugal machine goes into a cylindrical drum, with two sizes of holes—square and half square. As this drum revolves, its contents pass through the holes, in cube shapes, on to large plates that are conveyed by a mechanical carrier toward an oven, in which they are transferred for six hours of baking, after which the cubes are passed over an oscillating sieve for screening broken pieces, and are then dropped into cases or barrels, which are performing a sort of jim-jam waltz, in order to shake down the sugar as compactly as possible.

A great art in sugar boiling nowadays is to produce what is known as *fine grain*, that is concentrating the syrup until minute particles acquire a granular form, and then *feeding* these with liqueur till they have the appearance of large grains of yellowish colour. This kind is mostly sold as "pieces"

yellow moist sugar. To improve the colour of the sugar, a little sulphuric acid is generally put in the pans with the liquid sugar. The process known as "bluing," to impart a whiter and brighter appearance, is usually effected by suspending ultramarine in water, and applying it as a final wash, or let it into the vacuum for a few minutes before the batch or "strike" is finished. A teaspoonful is enough for a ton, but some beet sugars are so excessively blued that they yield a blue syrup on solution.

Genuine cane sugar possesses much higher sweetening power than common beet sugars, and no jam or British wine manufacturer would use any other.

Importers and Merchants.—Graham, Son & Hay, 16 Stanley Street, Liverpool; The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Canella Alba or **White Canella.**—A kind of cinnamon in small pipes. It is both outwardly and inwardly of a yellowish white colour, and thicker than ordinary cinnamon.

It has a fragrant smell, and a smart pungent taste, with the aromatic flavour of cinnamon, ginger, and cloves combined.

White Canella also yields, upon being macerated and distilled, an aromatic essential oil of yellowish colour, which sinks in water, and has the smell of oil of cloves.

Canica.—A sort of wild cinnamon growing in the Isle of Cuba. Its taste, however, is more like that of cloves than of cinnamon.

Canna Starch.—See *Tous-les-mois.*

Canned or **Green Corn, etc.**—(See also *Maize.*)—An American product consisting of maize (Indian corn), that has been gathered full-grown, but green and milky, and the grains or kernels of which have been cut from the cob and closely filled into clean tins, so as to leave no air-spaces. These are placed in a large oven or other air-tight vessel, and steamed from 4 to 8 hours; the harder the corn, the longer the exposure required to cure it. The lids are then soldered on, leaving a small vent-hole, and the full tins again boiled for about two hours. Immediately the steam has escaped and before cold air can enter, the hole is quickly soldered up. Sometimes the corn is boiled on the cob and cut off afterwards, which is perhaps the best plan. It is then filled into tins or "cans," and hermetically sealed.

The corn may be canned either way, and will keep good for years, but lacks much of the delicious flavour of the fresh gathered corn.

It is chiefly prepared in Maryland, New York, Maine, Iowa, Illinois, Ohio, and Virginia.

Fruits, Tomatoes, etc., are all canned in much the same way, but Green Corn, owing to its density, is one of the most difficult to preserve.

Canned Corn often sours from imperfect curing. It arises from the disease germs, either the microbe or bacilli. The first are round like minute balls, and the second are elongated or rod-shaped; both vary in size, and the growth or division is very rapid. With a microscope they may be seen darting and twisting in all directions. In the spore state they resemble small oval beads, and have no motion. In their normal condition microbes are easily killed in a boiling heat, and many will succumb even at a lower temperature. Most of the disease germs may be killed at 212° or lower, but 250° F. will make sure work of them, but the heat must reach the centre of the can.

About three million cases, of two dozen tins each, are put up yearly in the United States, prices varying from 2/- to 6/- per dozen tins in New York. Tinned corn is judged by whiteness, tenderness, sweetness, and juiciness, and these qualities vary considerably in different brands.

Canned Beets have now a good sale in the United States and Canada.

Machinery has reduced the cost of packing to a wonderful degree. One machine automatically sifts and separates peas into different grades or

sizes; another places the brine on them, and fills 18 tins at a time with the desired quantity of peas, and has a capacity of 5,000 to 6,000 cans per hour. Another cooks maize or green corn, and also fills the tins with the processed article. Another invention labels the tins in the most perfect manner with great rapidity, and then packs the tins in wooden cases. Other machines pack tomatoes in tins, and still others "cap" or solder on the lids.

Canned Fruits.—(See also *Bottled Fruits*, *Tinned Meats*, etc.)—It is a singular fact that we are indebted to Pompeii for the great industry of fruit canning. Years ago, when the excavations were just beginning, a party of Cincinnatians found in what had been the pantry of a house many jars of preserved figs. One was opened, and, although they had slumbered through many centuries, they were found to be fresh and good. Investigation showed that the figs had been put into jars in a heated state, an aperture left for the steam to escape, and then sealed with wax. The hint was taken, and the next year canning fruit was introduced into the United States, the process being identical with that in vogue in Pompeii twenty centuries before. Large factories are now occupied in this business, especially in America, where the growth of the industry has been phenomenal. The work being done in the summer and early autumn, a cheap building is all that is necessary. "Canning outfits" are sold complete by several firms. The outfit required for canning purposes is very simple, consisting of a large wooden vat, in which water can be rapidly made to boil by means of steam. This vat is provided with a basket made of small iron rods, hung by a tackle to a crane. This basket is to hold the cans, and is so arranged that it may be promptly lowered into or raised from the water. Cans cost about two cents. each, are made on the place by expert tin-workers, and by the aid of machinery three men will make 100,000 cans a day; the cost of labour, labels, and boxing is comparatively trifling. The profits are said t range from 25 to 40 per cent.

The fruits should be fully ripe especially apricots, nectarines, peaches and pears; not soft and mushy, but s that they will keep their shape. The are often canned too early, and, althoug these may look better, the flavour will b deficient, for flavour only comes wit ripeness.

Glass is best, but tin will do; onl there is the slight danger of the acid the fruit dissolving a portion of the ti

For home use the fruits are ofte merely cooked in a porcelain or granit ware kettle in small quantities of 12 20lbs. a time, and, when cooked, poure into tins or jars, and sealed at once.

If the finest appearance is desired, a fruit that is peeled or cut should be once dropped into water to keep it fro discolouring. By the aid of a silv spoon or knife the pieces can be arrange in the can systematically and regularl and the can should then be shaken dow solid as possible by gently jolting the table.

It should be filled with syrup. Th amount of sugar in this syrup is not ve important, but most people prefer a goo heavy syrup. The filled cans, with t covers loosely on, are now placed in boiler (a sort of "copper"), with wat enough to reach up nearly to the nec and the whole brought to a boil, a kept long enough to cook thoroughly.

Each fruit or vegetable, in order th it may keep, requires to be steamed "processed," as the boiling is calle for a given time; how long appears be the chief secret of the business, a depends largely on the ripeness of t fruit.

The following table shows averages:

	Time for boiling. Minutes.	Sugar quar fru Oz
Cherries	5	6
Raspberries	6	4
Blackberries	6	4
Strawberries	8	8
Plums	10	10
Whortleberries	5	8
Pie Plant	10	8

Sour Pears (whole) ...	30	4
Bartlett Pears (halves)...	20	6
Peaches (halves) ...	8	4
Peaches (whole) ...	15	4
Pine Apples (sliced) ...	15	6
Crab Apples	25	8
Sour Apples	10	5
Ripe Currants	6	8
Gooseberries	8	8
Wild Grapes	10	8
Quinces (sliced) ...	15	10
Tomatoes	20—½ teaspoonful of salt.	

The fruit shrinks considerably in ›oking, and, therefore, a few pieces, ith extra sugar, are cooked in a :parate dish to fill up with, if necessary. As soon as the cans are cooked enough ıey are removed from the water, the ›vers removed, and the cans filled as ill as possible with boiling hot syrup. hey are then wiped and soldered up, screwed down tightly with rubber-tted tops.

The fruit is then set aside, where it ın be watched for a week or so, and ıen, if no fermentation is noticed, it is acked in cases, or stowed away in a ark place to keep. If any can looks ›ubtful, the top is covered tightly with ›tton, and will then probably keep long ıough for home use.

To prevent the hot fruit breaking the ass jars, they are stood on a wet folded oth while being filled.

"I had the pleasure," writes a corre-›ondent, "while at Buffalo, of getting glimpse of a Convention of Canned oods Packers, and of visiting an ex-ibition of the machinery which is so :tensively used in preserving food. ne huge machine picks up the ears of :een corn or maize, carries it along, rips off the husks, brushes off the silk om the cob; another cooks the kernels corn, conveys it through a pipe to a ter, where it is packed into the tin can, hich is then sealed; another fills a tin ith peas and puts on the brine or quor. Others take the tins, place on e caps, brush in the soldering flux, ılder the cap, and pass the tin along. nother puts on the labels and packs ıe tins in boxes of two dozen each. They have a machine which takes the peas, strips off the pods, then shells the peas, and afterwards sifts them into six grades. The owner of this machine stated that he yet expected to perfect a machine into which pea vines could be fed, and, by automatic action, the pods taken off, the peas shelled, graded, packed into tins, and sealed. Here I found many machines for packing corn, peas, tomatoes, and having a capacity of handling 20,000 to 40,000 tins per day of ten hours. When one is witness to the wonderful extent to which machinery is used in the preserving of food, and how greatly it exceeds in amount of work the power of human hands, he begins to understand how it is a very good canned pea is sold at 2/10 to 3/- per dozen; corn and tomatoes at about the same price. I met one manufacturer who, by the aid of machines, turns out 60,000 pounds per day of condensed mincemeat, and will average that daily output for months at a time. Evidently the American's love of pie is not growing less.

"The attendance at the Convention reached nearly 300. There were some scientific papers read, in which the cause for the souring of sweet corn was given as due to the action of bacteria. The remedy is in preserving at a temperature of 250° F., for 60 minutes, under pressure. Of course a banquet and the inevitable speech-making is a feature of these gatherings."

If less than 8 ozs. of sugar be used to the pound of strawberries they are apt to lose much of their shape, freshness, and flavour, turning out pale, spongy, and insipid; but raspberries, on the contrary, seem to have their colour, flavour, and odour intensified. Success does not depend so much after all upon the amount of sugar used, as upon driving out the germs of fermentation by heating the fruit and excluding the air. Tomatoes are first scalded and peeled as for cooking, then boiled for about 15 to 20 minutes only, and canned as above.

By another method the article to be preserved is cooked for a short time first,

and then put into hot jars or tins, from which the air has been expelled by heating them to boiling point. They are at once sealed, and when cold are stored in a cool dark place.

Canned fruits are generally packed in 2½lb. tins, but some are also packed in 3lb. tins, and "seconds" or *pie fruits* in gallon cans.

All canned foods are best fresh as possible, and cans corroded inside should be rejected on account of the tin salts or stannic oxide incorporated in the food and likely to be injurious to health. Some authorities attribute the presence of these salts of tin to the use of hydrochloric acid employed in soldering.

Canned fruits, as well as canned fish, meats, etc., all contain larger or smaller traces of tin, caused by the feebly acid juices of the meats and by the more abundant acid juices of the fruits eating into the tin. Analysts have found from 1½ to 11 grains of dissolved metal in 1lb. cans, the larger proportions, however, being only found in some of the cheaper qualities of apricots.

The juice of the fruit being apt to dissolve some of the solder, or even the tin, although the metal is not actually poisonous unless consumed in large quantities, or by children when there is irritation of the bowels. The best packers, of course, by carefully selecting their tins, seeing they are free from scratches, etc., and using fruits of only a moderate acidity, render the risk of contamination from tin very slight. The "watered" deposit observable in the inside tin coating of cans of preserved fruit or vegetables, together with the discolouration of the contents, do not prove that they are bad or even going bad, unless they are absolutely coloured a brown tint. The stains are generally merely caused by sulphuret of tin, containing iron also, and this matter is formed by the decomposition of sulphuretted compounds in the vegetables themselves. The tint is darker, according as the fruits are older and were riper when canned.

Recently several fruit canning factories have been started in British Columbia, the principal being in Vancouver and New Westminster, where black currants, plums, pears, apples, etc., have often gone to waste.

California has a great fascination for fruit consumers, and although growers in the Eastern States of America aver that the flavour is much inferior to their own growths, yet it is a common practice in Baltimore and New York State to label other products as "*Californian*." In fact, labels on tinned goods are very unreliable, both as to quality of contents and place of origin. A case of Californian canned goods weighs about 65lbs. gross.

The care that is exercised abroad in canning goods, preserves the fruit and other food in good condition as a rule, but it cannot prevent stoned fruits, such as cherries and plums, from occasionally undergoing a change after being tinned for a certain time. These goods will often be found faulty in the spring, although all necessary attention was paid in the canning; it is, therefore, as well to use tinned fruits containing stones early in the season—that is, in the autumn—and reserve the peaches and apricots (from which the stones are removed), pines, etc., for consumption in the spring.

Cold Canning is now done in many households. Heating the fruit tends more or less to the injury of the flavour, and, instead of cooking, it has been found that by filling the cans with fruit and then with pure cold water and allowing them to stand until all the confined air has escaped, the fruit will, if then sealed perfectly, keep indefinitely without change or loss of original flavour.

Frost, of course, ruins the quality and flavour of fruit and vegetables, canned or fresh.

Special Firms.—M. & W. Jones, exporters, Villa Nova de Gaya, Portugal; and Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool, also proprietors of the "Orient" brand of Tomatoes.

Canned Meats.—See *Tinned Meats*.

Cannel Coal. — Sp. *Ampelita*. (Also known as *Candle Coal*, *Parrot Coal*, etc.)

A highly bituminous coal, opaque and brittle, breaking into more or less regularly formed cubes, and burning clearly, hence its name of *candle* or cannel coal. It is the best for gas making.

Found in Lancashire, Ireland, and Scotland. This coal is also susceptible of a high polish, and is often made into cheap trinkets resembling jet.

Cantal Cheese or **Fourme.** — A French kind made in the department of Cantal. It is of cylindrical shape, about as high as it is wide, and weighing 50 to 100lbs. The interior is whitish, full of small crevices, and fairly rich. The taste is rather peculiar, but appreciated by the Auvergnais, and the annual production is about 100,000 quintals.

Cantaloup. —A superior but small variety of musk melon, which takes its name from Cantalupo, the residence of the Popes, a few miles from Rome. (See *Melons.*)

Canter Cheese. — A term used in Cumberland for blue-milk cheese.

Cantharides or **Spanish Flies.**— F. *Cantharides;* G. *Spanische Fliegen;* It. *Cantaridii;* Sp. *Cantaridas.*

A kind of dried beetles, *Cantharis vesicatoria.* The beetles are about three quarters of an inch long and a quarter of an inch broad, with two long elytra or wing sheaths of a shining coppery green colour, under which are two thin brownish transparent membranous wings usually mixed with greyish brown powder containing bright green particles.

Their odour is somewhat strong and disagreeable, but they are valued for their stimulant and diuretic properties.

They are usually reduced to powder as required, for ointments, tinctures, plasters, etc.

Cantharides Vinegar.—See *Vinegar*

Cape Gooseberries.—An excellent fruit (*Physalis edulis*) resembling cherries, very popular in South Africa and Queensland. They also grow freely without any special cultivation in Madeira, where they are called *Tomates Inglez* (English tomatoes), and are in season from February to April. The flowers are white, and the berries yellow. In early Spring great quantities of these sweet and acidulous fruit are made into delicious preserves, but, so far, very little reaches this country, the pulpy nature of the fruit precluding its exportation in a fresh state. It is very nice when candied for dessert.

There is another variety of the plant, *P. Violacea*, which bears yellow flowers and violet-coloured fruit, but the yellow is the most esteemed.

Cape Madeira. — A heavy, boiled, and mixed sweetish wine, containing about 12 per cent. of alcohol.

Imported from the Cape of Good Hope.

Cape Tea. — See *Boer Tea.*

Cape Wines. — The leading descriptions of wine made at the Cape of Good Hope are :—(1) Sweet wines, under the general name of "Constantia"; (2) Dry white wines; and (3) Table wines.

The *sweet* are made from the highly ripened white and red Frontignac grapes, and from the red Haanepoot. The second description includes white wines belonging to the large categories of Madeira and South Spanish wines, particularly of the sherries, alicantes, and white ports. The chief sorts of grapes used for these are the Haanepoot and Muscatel.

The best red table wine is that made from the *grosse syrah*, a kind of "Hermitage" vine.

Pontac (described elsewhere under its name).—The white table wines are made from Riesling, Steen, and Spengler grapes, and appear in the market as "still hock" or "white Hermitage"; but are all far too alcoholic and heating for the climate.

Yearly production of Cape Wines is about 200,000 hectolitres.

Caper Teas. — (See *Chinese Teas.*)— These may be generally told by the leaves being rolled up into little lumps with starch or gum. As a class they are much adulterated, and, in fact, can hardly be called genuine tea. The

demand for them in England is now very limited. The boxes average about 21lbs. each.

Capers.—Du. *Kappers;* F. *Câpres;* Ger. *Kappern;* It. *Cappari;* Rus. *Kaperszii;* Sp. *Alcaparras;* W. *Sibr-flagur.*

These are the pickled flower-buds of the caper plant, *Capparis spinosa,* very common throughout the South of Europe, and nearly allied to nasturtions.

The bush, or "alcaparra," is a low trailing shrub often growing on old walls, fissures in rocks, or over rubbish heaps, and bears white and purple blossoms. The plant is also largely cultivated as a garden ornament. Each bush yields about a pound of capers yearly. The buds are usually picked every morning as they approach maturity from May to November, exposed in the open air for 24 hours, and then thrown into a cask or other vessel of strong white pickling vinegar, and when full these are headed up and sold to the wholesale merchants.

These merchants sort them into different sizes by means of copper sieves, and in this way they are divided into various grades, such as *Communes,* ordinary value about 15/- per cwt.; *Mi-fines,* 32/-; *Fines,* 36/-; *Capotes,* 40/-; *Capucines,* 50/-; *Surfines* (or Superfines), 58/-; and *Nonpareils,* 84/. The last, being the youngest and smallest in size, are considered the choicest; while Communes are the largest and cheapest. The agreeable taste and sharp acrid flavour for which capers are so valued seems to be the capric acid—$C_9H_{19}CO_2H$, called also rustic or decatoic acid—which, in large quantities, has the offensive smell peculiar to goats.

Capers also contain a gelatinous substance, related to the *pectin* group.

Their greenish colour is heightened by the copper wires in the sieves, but sometimes copper coins are put in by the country people, and for retail purposes capers are generally put up in green bottles. The finest quality of vinegar, previously boiled and cooled, is generally used, inferior kinds being apt to spoil the capers. Those grown in the South of France are considered to be the best, especially those of Provence; Roquevaire, Cuge, and Ollioules growths, firm and of good colour, have long been held in high repute, and will keep good for several years. Capers are usually very cheap in Marseilles in June, July, and August, but buyers should beware of Spanish and other inferior kinds, commonly labelled and sold as "French capers," although they have merely been imported *by way* of France, hence the port of shipment is no proof of their origin.

Besides France and Spain, considerable quantities come from Italy; another cheaper quality from Algeria, and a few small salty capers arrive from Majorca. A flat shaped variety also comes from Lyons.

The presence of copper colouring in capers is easily detected. Take a teaspoonful of the liquor and put it into a wine-glass, add a little water, and then an excess of ammonia solution; if copper be present, a beautiful blue colour will be produced. The ammonia solution should be strong, and well stirred in with a bit of glass rod, which can be had at any chemist's shop for a few pence.

A simpler test is to immerse the clean steel blade of a penknife or a knitting needle in the caper liquor, and leave it there overnight; next morning examine it, and if copper be present there will be a red deposit of pure copper on the surface of the penknife or needle. It is best not to add water in using this latter test, and if there is much copper the steel then becomes coated with it very quickly.

Special Importers.—Charles Cocks & Co., Reading.

Capillaire.—Lat. *Herba Capillorum.*

A syrup made by infusing 2 ozs. of the Maidenhair Fern, *Adiantum Capillus Veneria,* in 1½ pints of boiling water, and 2lbs. of pure cane loaf sugar, which is poured while boiling hot on 2 ozs. more of the fern, and about two hours afterwards strained clear.

Another recipe:—16lbs. lump sugar

and 6 eggs, well beaten; boil in 3 gallons of water, and skim it as long as any scum appears; then strain through a bag, and, while warm, add a few drops of essence of lemon.

It is often prepared from simple sugar syrup, perfumed with orange flower. Retailed in 6d. and 1/- bottles.

Capsicums. — F. *Piment des Jardins, Piment rouge;* G. *Spanische Pfeffer, Schotenpfeffer;* Lat. *Capsici fructus;* Port. *Pimentos;* Sp. *Pimientos.* (See also *Chillies, Bird Pepper, Cayenne, Paprika,* etc.)

There are several species of capsicums. *C. annuum,* known also as Guinea pepper, exists in an enormous number of varieties, especially in Central America, but also in Japan, West Indies, Natal, and Zanzibar. One of its varieties, used for feeding birds, is more fully referred to under *Bird-Peppers. C. cerasiforme,* or Cherry Pepper, has cherry-shaped red and yellow pods; *C. dulce, C. americanum,* or *C. tomatoforme; C. baccatum,* see *Bird Pepper; C. grossum,* or *Bell Pepper,* native of India, etc., etc.; *C. fastigiatum Bl.* (*C. minimum Roxb.*), or smallest Red Chillies; *C. tetragonium,* etc., etc.

The Capsicum is a comparatively hardy plant, but the fruit has very little flavour. The *Capsicum grossum* is very popular, and the only kind proper for pickling, its skin being thick, soft, and tender, whereas that of the other sorts is thin and tough.

The shrubby capsicums of Sierra Leone, distinguished as *C. fastigiatum Bl.* (*C. minimum Roxb.*), or *Small red chillies,* are scarcely an inch in length, a line or two broad, and of a deep orange red colour. These last are hotter, and possess considerably more aroma than the other species of capsicums. Each pod encloses about a dozen flattened reniform seeds. They are cultivated very extensively on the south-east of Zanzibar by the Wahadinu people, as also is another variety bearing larger red and yellow pods, but this is all consumed locally. As a rule, Zanzibar capsicums are of a brownish red colour, dirty looking, and inferior, but very hot. Those from Japan, on the other hand, are milder, sometimes rather sweet, or almost tasteless (see *Japanese Pepper*). The kind imported from Natal is an inferior variety of *C. annuum,* much larger than "Chillies," and of a dull brownish-red colour, also very pungent. The yellowish red pods grown in Sierra Leone are also very pungent, but inferior in aroma and appearance. The names of the different varieties are, however, very much confused, and the terms capsicums, chillies, red peppers, red bird-pepper, cayenne pods, birds'-eye chillies (very small and red), guinea pepper, chili pepper, maleguetta pepper, grains of paradise, are all used promiscuously in different parts of the country; but, as a rule, in commerce, the smaller pods are called "Chillies," and the larger "Capsicums."

The plants bear white flowers, and grow luxuriantly in most hot countries. In the south of India they grow wild, and form the chief seasoning used by the natives. (See *Nepaul Pepper.*)

The drier and hotter the soil, the more pungent the fruit. In all tropical countries some form of capsicum is an article of daily diet. It seems to be nature's tonic for the stomach in hot climates.

Immense quantities are eaten raw and green, some are pickled, others made into chutneys and curries. When red-ripe they are generally exported either in cask with salt and water, or dried in the sun and baled. They are often pickled in brine, and used in seasoning mixed pickles, sauces, etc. Also dried and ground into powder to make "cayenne pepper."

Capsules.—See *Metallic Capsules.*

Captain Biscuits. — Captain Biscuits are very similar to *Sea Biscuits,* but are made from finer flour. Take 8lbs. of flour, ½lb. butter or lard, and a quart of milk. The dough should be thoroughly kneaded, or broken by break, or in machine, till quite smooth, and baked in a fairly quick oven.

Capucines.—See *Capers.*

Caracas Cocoa.—This is a fine quality of cacao, grown in Venezuela. It used to be considered superior to any other, but has been surpassed by the Ceylon product. The best qualities come from Ocumare and Caracas, and the more ordinary from Rio Chico and Higuerote (Port Carenero).

The method of curing in Caracas is first to spread out the newly gathered pods in the shade of an outhouse for a week or so to mature. They are then opened with a knife, and the seeds or beans, spread on tables, are exposed to the sun until they turn red. They are next covered up closely with banana leaves and fermented or sweated daily in a cool place for four or five days, but are stirred and aired every morning and evening. After this they are again spread out and dried in the sun till they sound hollow, when they are ready to be sacked for the market.

The beans, or seeds, are more spongy than the *Criollo* kind (see *Cocoa*), and 14 to 16 pods yield 1lb. of beans.

The manufactured article sold in England as "Caracas Cocoa" is understood to be prepared from about 50 per cent. of this kind of cacao, with arrow-root and sugar added.

Caraburna Raisins.— These come from Samos, a Turkish town in Asia Minor. They are very plump and sweet, and are largely used in France, in their dried state, for wine manufacture.

Carambolas. — The fruit of *Averrhoa Carambola*, imported from the East.

Caramel. — See *Burnt Sugar Colouring.*

Caramels (Sweetmeats).—These were of American origin, but the English makes are now generally preferred. Usually made up of glucose, sugar, milk, and butter or cream, and exquisitely flavoured with chocolate, vanilla, etc., etc. They are either moulded or cut in the shape of dice, each piece being afterwards wrapped in waxed paper.

Caravan Tea.—A commercial name for tea grown in China, packed into large bales, covered with lead, and carried into Russia entirely overland. It used to have the reputation of being the best tea produced in China, and some say its superior and delicate flavour is enhanced by this mode of transit, or, at least, preserved from the "ship smell" of teas coming to Europe, but now only common grades are sent overland. (See *Brick Tea.*)

Caraways.—See *Carraway.*

Carbolic Acid.—F. *Acid phenique*; G. *Carbol säuren*; It. and Sp. *Acido fenico.*

This acid, or *Phenol*, as it is technically termed, is a very abundant product in the distillation of coal, and recognised as a valuable disinfectant and deodoriser. It is also an excellent antiseptic, and largely employed in surgery as a wash for ill-conditioned ulcers and gangrenous sores. Weak carbolic acid has been found to be a valuable protection against the bites of gnats and insects. Sponged on the skin and hair, and in some cases the clothing, it will drive away the whole tribe. The safest plan is to keep a saturated solution of the acid, which cannot contain more than 6 or 7 per cent., and it may be added to water until the latter smells strongly. This may readily and with perfect safety be applied with a sponge. Horses and cattle may be protected in the same way from flies, which sometimes nearly madden them.

Carbolic Deodorising Powders.—These are of various strengths, but their basis usually consists of a mixture of freshly slaked lime (dry) and ordinary whiting coloured with rose pink. An infusorial earth, known as *Kieselguhr*, is used for the better sorts, and is much more absorbent. It may be coloured in the same way. A deodoriser is not always a disinfectant.

Carbolic Soaps. — These if well made possess great disinfectant and deodorising powers, particularly if they contain not less than five per cent. of phenol, and are invaluable for washing

linen of fever patients, also for cleansing infected chambers. A strong carbolic soap generally contains about 1 part of carbolic acid to 9 parts of soap, but this is too strong for personal use, and a milder variety known as carbolic toilet soap is prepared for this purpose, in which about 2 per cent. of carbolic acid is added to the soap while in a melted state, and thoroughly incorporated by "crutching."

Its thorough incorporation, without leaving the product soft, requires considerable skill, and the best methods are, in fact, considered secrets. A good carbolic soap is made of the following:—20lbs. half-palm soap; 1lb. starch; 1 oz. carbolic acid in crystals and perfumed with 2 oz. oil of lavender and 1 oz. oil of cloves.

Carbonade of Meat.—A piece of meat, fowl, or game, cut, sliced, or scored across, and seasoned, and highly broiled or grilled over a coal fire, almost "carbonised" or burnt. These dishes are very popular in Germany and other northern countries.

Carbonate of Ammonia. — See *Ammonia.*

Carbonate of Soda.—F. *Carbonate de Soude;* G. *Natriumcarbonat;* L. *Sodium Carbonate.* (See also *Washing Soda.*)

The word "carbonate" is applied in a general way to any salt which has been formed by a combination of carbonic acid and some other base. Therefore, carbonate of soda means a combination of carbonic acid and soda.

Also known as crude soda, alkali, soda ash, etc. Soda is procured from several sources. In Egypt, Hungary, and some other countries it is found as an incrustation in dried-up soda lakes in the summer season. Some is obtained from "barilla," the ashes of kelp and other plants growing on seashores.

It is also produced from *Cryolite*, a mineral found in Greenland and in the Ural Mountains. This mineral being ground to powder is mixed with lime, water is added, and it is then boiled. But the great bulk of the carbonate of soda of commerce is prepared at chemical works from common salt. The salt being first dissolved by sulphuric acid, and afterwards roasted with lime, chalk, and small coal, is next formed into a pasty substance called "black ash." This black ash, when drawn from the oven and cooled, is then acted upon with water, and a solution is obtained which is finally evaporated and calcined into the form of carbonate of soda. Soda is, as we know, decomposed by the action of heat, and carbonic acid is given off with the formation of a sesqui-carbonate, which in turn is transformed into a normal carbonate.

The mode of manufacturing it from common salt was invented by a Frenchman named Leblanc, at the end of last century, in competing for a prize offered by Napoleon; and has since made way for the simpler "ammonia process," whereby a solution of common salt is treated with bi-carbonate of ammonia, and by this *bicarbonate* of soda is produced.

Bicarbonate of Soda.—*Carbonate* of soda, as above shown, is a salt formed by the union of carbonic acid with the base (soda) $NaHCO_3$. When the base is imperfectly saturated with the acid, the salt formed is called a *sub-carbonate*, and when there is an excess of acid, *bi-carbonate.*

Sesqui-Carbonate of Soda.—*Sesqui* is a Latin prefix meaning a *whole and a half;* hence sesqui-carbonate of soda is a concentrated compound, in which an equivalent and a half of carbonic acid combines with one of soda. It is technically represented by $Na_4H_2(CO_3)_2H_2O$, and is the best form of washing soda, doing about twice the work of common *Sal Soda.* Over 350,000 tons of carbonate of soda are made yearly in this country. It is used in enormous quantities in the arts and manufactures, has a stronger alkaline taste than the bicarbonate of soda, and is more readily soluble in hot water. Although all these preparations are commonly called "Carbonate of Soda," the white powder usually dealt in by grocers and druggists is either bicarbonate or sesqui-carbonate,

and the proper carbonate of soda is, as a rule, only used in manufacturing operations.

Gardner's patent "Rapid" Sifter and Mixer is freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Cardamoms or **Elatchee.** — Da. *Cardamomer;* Du. *Kardamomen;* F. *Cardamomes;* G. *Kardamum;* It. *Cardimomi;* Rus. *Kardamom;* Port. and Sp. *Kardamomos;* Sw. *Kardemummer;* W. *Grawn Paradwys.* (See also *Grains of Paradise.*)

The spicy and bitter seeds of a reed-like plant growing five to ten feet high in Southern India, China, Ceylon, and Java, known as *Amomii Cardamômum.* They are largely grown in Malabar, where the plants are called *Elettari.* In Travancore cardamoms are a sirkar monopoly, and cultivated in gardens of about 20 acres by the ryots or native farmers.

There are many varieties, both wild and cultivated, and, in commerce, they are merely divided into three grades, viz., "shorts," "short-longs," and "long-longs," according to their length. It is also customary for several kinds to be also mixed together and classed as the greater or the lesser cardamoms. The chief exports are from Cochin China, Annam, and Tonking, and amount to about 100 tons a year; but, as with certain other Chinese products, very little is to be learnt about them botanically. They are usually packed either in gunny bags, or in large chests, well jointed and pitched. The seeds, about the size of mustard seed, are of dark brown colour, of pleasant smell, and aromatic taste, and grow in three-cornered pods of pale colour and about half an inch long. They also possess hot, pungent, carminative, and stomachic properties, yielding about three per cent. of oil, and are largely employed in medicine, especially in veterinary practice, as well as in culinary sauces, soups, curries, cordials, cake seasoning, etc., but mostly for imparting a factitious strength to beer and spirits. They lose their strength quickly when ground, and should be chosen in the pod, close shut on all sides, each pod full of seeds of pleasant smell and an acrid aromatic taste.

The ovoid cardamom, the fruit of Amomum medicine is a native of south-western Kwangsi, as well as of Tonquin. Ground cardamom are often adulterated with the wild cardamoms of Ceylon, Siam, and Korarima, but the pericarps are distinguishable by their bast fibre, the wild seeds being also characterised by the thick walls of their epidermal cells.

Wholesale prices, 3/- to 4/6 per lb.

Cardon, Cardoon, or **Chardoon.** —F. and Sp. *Cardon;* Lat. *Carduus.* (See also *Artichokes.*)

A prickly species of Cynara (*C. cardunculus*), closely related to the thistle and the artichoke, but larger. They should be tall and upright, and the ribs of the leaves of fleshy consistency. The cardoon differs from the cultivated artichoke in that the ribs of the leaf of the former have been developed, whilst in the latter the flower heads have been the objects of selection. Mostly imported from France, and sold in tins of ½lb. 1lb., and 2lb. sizes.

Also cultivated in this country. The seeds should be sown in heat—three seeds in a 40 pot, removing the two weaker ones when it is seen which is the strongest seedling. Harden off in a cold frame when the roots get round the sides of the pot, and plant them out in May in trenches 18 or 24 inches apart in the trench, and five feet from trench to trench.

In the Pampas of Buenos Ayres the cardoon, although only naturalised there during the 19th century, has grown wild and spread with such abundance as to obstruct travel and traffic in some parts.

The plants require much water when growing, also when blanching, but are very useful vegetables, although the flavour does not please everybody, and they are often grown merely as garden ornaments.

Cargo Rice.—A term applied to the coarse but sweet and large-grained rice which is principally exported from Bengal, only about one part in five being husked. It is preferred by the natives to every other sort. This rice is not kiln-dried, but is parboiled in earthen pots or caldrons, partly to destroy the vegetable principle, so that it may keep better, and partly to facilitate the process of husking.

Carlowitz Wine.—A sound red wine produced near the town of this name, and the best known of Hungarian wines.

It has a rather rough taste, not unlike Burgundy, and is very popular as a dinner wine.

Carlsbad Sugar Wafers. — A dainty wafer-like kind of dessert biscuits, very thin and delicate, with a sprinkling of fine sugar between.

Carmine. — Du. *Karmyn;* Fr. *Carmine;* Ger., Pol., and Rus. *Karmin;* It. *Carminio;* Dan., Sp., and Sw. *Carmin;* W. *Lliw Coch.*

A very beautiful red or carnation-coloured pigment bordering upon purple; a species of lake in powder; largely employed by artists in miniature. The best for colouring foods is made of finely pulverised cochineal by means of water in which "*chouan*" or "*antour*" has been infused. It is, however, well known that much of the carmine prepared from cochineal does not consist of the pure pigment, as it generally contains a considerable amount of ash which should not be there. Others prepare it with Brazil wood, pernambouc, and leaf gold, beaten in a mortar and steeped in vinegar, the scum which arises forming an inferior carmine. Carmine is also made with carbonate of potash, alum, and fish-glue; but this requires very skilful manipulation. Carmine used to be very high-priced, but since the discovery of aniline colours its value has considerably lowered.

Carminic Acid. — See *Cochineal Colouring.*

Carnauba Wax.—(See also *Vegetable Tallow.*)—This hard and brittle wax, often called *Ceara* or Brazil Wax, because it is indigenous to the State of Ceara, is obtained from the young leaves and berries of a black palm (*Copernicia cerifera*) and others in Brazil. The leaves and crushed berries are steeped in boiling water, and the wax rising to the surface is skimmed off. It forms a crisp, translucent covering on both sides of the leaf, and may even be scraped off with a knife, or it may be shaken from the leaves after rubbing or beating them together.

It has an agreeable smell. Unless harvested while the leaves are young, it falls off of its own accord when they are more fully grown. The wax is then dried and stamped in a mortar, and then fused to separate it from other bodies which the scales contain.

Its chief value arises from its high melting point, which is said to range as high as 80° to 90° C. Hence it is employed in many ways—to harden beeswax and stearine in the manufacture of candles, to wax floors, to insulate electric wires, etc.; it is also used by furniture-polishers and brass-finishers in putting an extra polish on their wares.

The qualities vary from light brown, greenish-grey, to pale yellow; also the prices, from 40/- to 80/- per cwt. respectively.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, E.C.

Carne Liquida. — The liquid meat extract, as invented and prepared by the Uruguayan chemist, Dr. Valdes Garcia, in which he combines the qualities of extract of meat with the nourishing properties of the meat itself. The great bulk of the liquid meat extracts on the market are obtained through this source. An immense quantity is manufactured, but, so far, the secret of production remains with Dr. Garcia, and he takes care to guard it.

Carob Beans.—See *Locust Beans.*

Carolina Rice. —(See also *Rice.*)—This rice, raised on the low, marshy grounds of South Carolina, U.S.A., is unquestionably very superior to any brought from any part of India. It was first raised in South Carolina from seed

taken from Madagascar about the end of the seventeenth century. It is very broad and short, and usually very much broken up. It is very mucilaginous, and boils softer than Patna; but very little of this excellent kind now leaves America, selected Patna, Java, and other East Indian rice, worth only about half the price, being often sold as Carolina in this country.

Of course, the sellers render themselves liable to very serious penalties, under the Merchandise Marks Act. Some try to evade the Act by selling the substituted article as of the "Carolina kind," which, of course, is not Carolina at all. Genuine Carolina comes mostly to Liverpool, but cannot well be retailed at less than 5d. or 6d. per lb.

Carolina Tea. — Made from the leaves of *Ilex vomitoria.*

Carpet Soap. — The best known and most reliable article in this line is *Sadler's Marvellous Carpet Soap.* Sells at 4½d. and 8d. per bar. Packed in 14lb. boxes; to cost 7/-, sells for 10/-. From usual agents, or the Depot, 160 North Street, Brighton, Sussex.

Carrageen. — The proper name for Irish Moss, a well-known alga or seaweed, *Chondrus crispus*, which abounds at the town of Carragaheen, near Waterford, and about Sligo, in Ireland. It grows far down on the rocks, and is only uncovered at low spring tides. It is a deep rich green when gathered, but when washed, dried, and bleached by sunlight, it turns to a yellowish-white or straw-colour, horny and translucent. It has valuable emollient and demulcent properties, containing 63 per cent. of *carragheenin*, an agreeable jelly-like starch, but not a particle of gelatine. It is popularly known as *Irish Moss*, and is used in invalid cookery, making soups, blanc-mange, etc.

Characteristics of best quality.— Foliaceous, crisp, smooth, whitish, odourless, tasteless, mucilaginous. A strong decoction gelatinises on cooling. It possesses adhesive and stiffening powers, and dries down on the fibre, which it will not injure, nor change sensitive colours.

The same kind of moss is also found on the coast of Massachusetts and at Hamburg.

Half an ounce soaked for ten minutes in three pints of water, then boiled, strained, and flavoured, yields a very pleasant drink; or if sugar and milk be used instead of water, a pound weight of stiff jelly or blanc-mange is produced.

Carrageen is fed to cattle in times of scarcity. For feeding calves, wash 1lb. of dry moss in cold water, then boil 3½ or 4 hours, and when lukewarm strain and mix with bran or milk. For cattle or pigs, boil 1lb. of the moss in 10 gallons of water, and when cold, mix with oatmeal, barley meal, or Indian meal; for horses, with cut straw or hay. It is also made into size for thickening calico, and employed as stuffing for mattresses, etc.

"New seasons" crop cheapest and most plentiful latter end of August. Prices, 15/- to 25/- per cwt.

Carraway Comfits. — See "*Comfits.*"

Carraway Essence and Oil. — The oil is colourless or pale yellow when new, has an aromatic and somewhat acrid taste, but it turns darker with age. Its value depends on the amount of *carvol* it contains. Frequently adulterated with oil of cummin.

It should have a density of at least 0·910 at 15° C., not more than 15 per cent., should distil over below 185°, and 55 per cent. should come over above 200° C. The rotary power varies from 79° to 80°.

If kept long, a plenol is formed; and to this is due the blue colouration given by ferric chloride.

Carraway Essence is commonly made by mixing about ¾ oz. of the oil with 12 ozs. of rectified spirits.

Carraway Seed (often spelt Caraway).—F. *Fruits de Carvi, Cumin des Prés;* G. *Kümmel;* It. *Carvi;* Port. *Alcaravie;* Sp. *Alcarabea;* W. *Garddy.*

The deep brown seed, or more correctly the mericarp, of the small umbelliferous plant *Carum carui*, growing wild in some parts of Europe, but largely cultivated in Germany, Holland, etc., and in our own counties of Essex, Kent, and Suffolk. The plant is a biennial, grows 2 or 3 feet high, with pinkish white flowers and has a tapering root like a parsnip, but much smaller. This root, when young, is good eating. The seeds are oblong, pointed at both ends, thickest in the middle, striated on the surface, and more or less crescent shaped, with a strong aromatic smell and warm pungent taste.

The German and Dutch, of light blue-brown colour, are larger, but the English is most esteemed. The Bohemian, Polish, and Russian seeds are ordinarily of blackish colour and small grain, and often mixed with dirt and *débris* of the fruit-stalk. About 1,000 tons of these are imported yearly, *viâ* Holland. Occasionally a large pale variety is imported from Mogador, and is about half as long again as the English.

"*Drawn*" *Carraways.* — The exhausted seeds after the oil has been expressed; value about 1d. per lb., but often mixed with genuine or ground seed. The drawn seeds are much darker in colour, and, of course, lack the volatile oil and the pleasant aromatic smell of unexhausted seeds.

Carraways of low dark colour may be much improved by damping them, and submitting them on trays to the fumes of burning sulphur in a close chamber, or other similar contrivance.

Carraway seed is used in medicine as a carminative, and as a spice to flavour liquors, cordials, bread, cakes, confectionery, etc.

Carraway comfits or *Scotch Carvie* are these seeds coated with sugar and generally coloured pink or white. It should be chosen new, large grained, bright coloured, free from dust, and of strong agreeable smell.

Apply to Hedley, Gamble, & Crosfield, Circus Street, Liverpool; or to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Carrots.—F. *Carottes;* G. *Carotten, Mohren, Gemeine Cahre, Gelle Rube;* It. *Carota;* Lat. *Daucus Carota;* Port. and Sp. *Zanahorias;* W. *Moron cochion.*

These are next in importance as vegetables to onions and potatoes; they grow wild in the countries around the Mediterranean, and are now cultivated in most parts of the world. They are of biennial growth and native of Britain. Large quantities are grown in Suffolk. In Germany they are sometimes cut up into small pieces and roasted and then used to make a drink instead of coffee. New English carrots come into the markets about June; but considerable quantities of small young ones done up in bunches arrive from France in April. Price 6d. to 1/- per small bunch. Carrots, potatoes, beets, and parsnips keep best in a cellar on dry earth or sand, and when fully grown. Those beginning to sprout should be used first.

As food, carrots are somewhat indigestible, but are heat-giving, and much used for flavouring soups, stews, and sauces. They contain 89 per cent. of water and 4·5 per cent. of sugar.

As an ornament, the upper part of the root is occasionally placed in a hyacinth glass with water, and the young leaves sprouting out green and fresh are very pretty.

The garden carrot was first introduced into this country in the reign of Elizabeth, and ladies used to wear the elegant and graceful leaves of the carrot in their hats instead of feathers; and even as a food it was cooked in greater variety of ways than at present. The leaves were commonly used as "greens." Carrots are more popular in France than in this country, and enter into a large number of dishes. Syrup, jam, and wine are sometimes prepared from carrots; they can also be fermented, and used in beer instead of malt, and in distillation they yield a considerable amount of spirit. The best carrots are of light red or yellow colour, of conical shape, sweet, and crisp. Young carrots are more tender and preferable for the table, and are in season from April to June. The small dwarf carrots, so much

esteemed by gourmands and resembling overgrown radishes, come from France. (See "CRECY.")

Carrot Soup. — (See *Purée*, or *Potage Crécy*.)

Carvie, or **Carvie Comfits.** — Scotch names for Aniseed or Carraway Comfits—seeds preserved and coated in sugar and dried. (See "*Comfits*.")

The word *Carvie* is properly the name for a variety of bastard or Vosges aniseseed. It used to be sold by grocers, but is seldom met with nowadays, and the other seeds named are substituted. Carvie seed is, however, used in the preparation of certain liqueurs, such as *Kummel*, also in some kinds of German biscuits.

Cascara Sagrada. — (Sacred Bark) —A tonic purgative, from the bark of *Rhamnus purshianus*, a species of buckthorn.

Cascarine. —A proprietary food made from maize.

Casein. — F. *Caséum*, or *Caséine*.

The solid part, curd, or nitrogenous constituent of milk, and out of which cheese is made.

Cashew, Caju, or **Acajou Nuts.** —Du. *Catsjoenooten*; F. *Noix d'acajou*; G. *Akajunüsse*; It. *Acaju*; Port. *Noces d'Acajou*; Sp. *Nueces de acajou*.

A kidney-shaped nut, about an inch long, the produce of a tree called *Anacardium occidentale*, which grows in South America and the West Indies.

Along the sea shores of Western India the cashew-nut tree is the predominant tree of the woods in the neighbourhood of towns and villages.

In Makualand, East Africa, the trees are very extensively cultivated by the natives, and a very strong spirit, called *Arripa*, is distilled from the fruit. The cashew tree is very like a walnut tree, and the leaves—broad and large—have a similar smell. It has very little bloom, and the bluish shell-like nut, which is the only part that will keep good for exportation, grows out at the top of a large fleshy pear-shaped fruit or swollen stalk. The kernel, forked like that of a walnut, is in a very hard double shell, between the layers of which is a black oily juice, so acrid and caustic that if touched by the lips or fingers it sometimes burns the skin and causes blisters.

This acrid property is, however, neutralised by heat, and the kernels are then eatable and of very pleasant taste. Not only is the roasted kernel edible, but also the pear-like enlargement of the floral receptacle. In the tropics the nuts are commonly used in cooking, and greatly improve the flavour of chocolate. The oil is used as an indelible marking-ink for linen. In England the kernels of cashew nuts are often sold in bottles, and used at dessert after being well roasted. Cashew stones are largely used in German confectionery; and the nuts make capital monkey heads for dolls.

Cashmere Chutney. — (See also *Chutneys*.)—An Indian condiment, very hot and sour, composed of sliced fruits and spices.

Cassareep. — (Also called *South American Cassaripe*.)—A West Indian sauce made from the expressed juice of the Cassava or *Manihot* root (see both), concentrated and freed of its volatile poisonous properties by heat and exposure, to the consistence of treacle, and flavoured with pepper, cinnamon, and mace. The scum is carefully removed during the process. It is used as a condiment in the West Indies and in making sauces. Some travellers from the West Indies (Mr. Davitt among others) say that much of the cassareep is prepared by natives chewing the plant and expectorating the juice.

This juice when freshly obtained is highly poisonous, and has to be well boiled to render it innocuous.

Importers.—The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Cassava. — F. *Cassave*. (See also *Mandioca*, *Yucca*, etc.)

A West Indian name for the shrub *Manihot utillissima* and its congeners, largely cultivated in many tropical

countries for its valuable products, such as Tapioca, Cassareep, Onycou, and Farina.

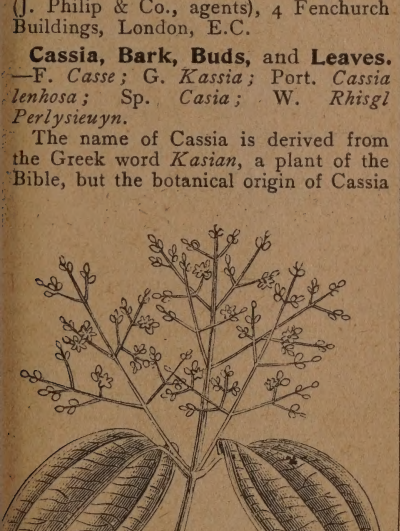
The bitter and some of the sweet Cassavas contain a poisonous amount of hydrocyanic acid, but, by exposure to light and air and drying, the poison is decomposed, and the edible substance becomes quite harmless.

In Florida it has been found to yield a larger percentage of mercantile produce than any other of the bulbous plants, say, 30 to 40lbs. to the root, and 3,000 roots to the acre. This equals about 45 tons. When dressed the root produces about 30 of syrup or glucose, 40 of starch, and 10 per cent. of tapioca.

Importers.—The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Cassia, Bark, Buds, and Leaves.—F. *Casse;* G. *Kassia;* Port. *Cassia lenhosa;* Sp. *Casia;* W. *Rhisgl Perlysieuyn.*

The name of Cassia is derived from the Greek word *Kasian*, a plant of the Bible, but the botanical origin of Cassia



CASSIA.

Lignea of commerce (Cassia Bark) has long been involved in considerable mystery and uncertainty. Many grocers and spice merchants and others who ought to know better have been content to imagine it the outer bark of the common cinnamon tree, but such is not the case; for the trees, although both of the laurel order, differ in many particulars. The bark of the Cassia tree is thicker, rougher, denser, less quilled, breaks off shorter, and is not so agreeable in flavour or perfume as the produce of the sister tree. Powdered cinnamon is an astringent medicine in diarrhœa. but powdered cassia has no such property. Some varieties of Cassia are grown in Java and other East Indian Islands, but the bulk of the cassia sold in England comes from China, *viâ* Canton. It is grown in districts where Europeans are not settled, and have rarely visited. The Chinese have long managed, with their usual shrewdness, to keep its cultivation and curing processes to themselves.

The subject having long excited a keen interest in scientific and commercial circles, it was decided in 1882 between Lord Kimberley, then Secretary of the Colonies, and Sir J. D. Hooker to send up to the Cassia districts Mr. Ford, head of the Botanical Department at Hong-kong, for the purpose of gaining information, if possible, and reporting on the subject.

Mr. Ford proceeded up the West River, Sai Kong, in the month of May, and, besides much interesting information, brought back with him about 1,700 young Cassia plants from the districts of Loting and Lukpo, in the Kwangtung Province, and Taiwa, in the Kwangsi Province, with the view of distributing same in any places suitable for Cassia cultivation. The only tree from which cassia bark, buds, and leaves of commerce are obtained in China, appears to be the *Cinnamomum Cassia Blume* (Yuk Gwai she), a medium-sized, stiff, ornamental tree, growing 20 to 40 feet high, if allowed, and with a trunk about 3 feet in circumference. But few trees attain this height. The plants are raised from seeds, and the tree has not been met with in a wild state; and like most of the order Lauraceæ, to which

cassia belongs, the seeds must be sown very shortly after they mature, or otherwise they rapidly lose their vitality. They are sown as they ripen, from February to April, at about three inches apart, in drills two inches deep and one foot apart in beds prepared beforehand in the open air, each bed about six feet wide and any length desirable. The beds are raised about nine inches above the surrounding ground. In about three weeks the seedlings appear above the ground. These only require an occasional watering till ready for transplanting a year or two afterwards into the permanent plantations, which must be on the hillsides. The plants, being lifted from the seed beds with a portion of the long tap root, are arranged 3 feet apart, and any gaps caused by the decay of trees in the older plantations are also filled up with young plants.

When the trees are about six years old the first crop of bark is obtained. The season for barking is March, April, and May, but after that time the growing bark loses its aroma, and is not, therefore, gathered. The branches, which are about an inch thick, being cut to within a few inches of the ground, are carried to houses or sheds in the vicinity of the plantations. All the small twigs and leaves being cleared off, a large bladed knife, with the cutting edge something like the end of a budding knife, is used to make two longitudinal slits and three or four incisions, at sixteen inches apart, round the circumference through the bark. The bark is then loosened by passing underneath it a kind of slightly-curved horn knife, with the two edges slightly sharpened. Pieces of bark 16 inches long and half the circumference are thus obtained. The bark, after its removal and while it is still moist with sap, is then laid with the concave side downwards, and a small plane passed over it and the epidermis removed. After this operation the bark is left to dry for about twenty-four hours, and then tied up in bundles about 18 inches in diameter and sent in to the merchants' houses in the market towns.

Cassia Leaves.—The leaves, which are cleared from the branches that are barked, are carefully preserved and dried, and afford by distillation cassia oil. A large quantity of leaves are sent to Canton where the operation of distilling is performed.

Cassia Twigs.—These are removed from the cut branches at the same time as when the leaves are obtained. They are a marketable commodity for native uses.

Cassia Buds.—Cassia buds, about same size as small peas, are the immature fruits. They are gathered when about one-eighth grown, and have a rich flavour nearly equal to cinnamon. Buds, and the seeds which are annually required for sowing, are obtained from trees ten years and upwards of age, that are left standing at about fifty and a hundred feet apart amongst the trees which are cut down every six years for their bark. These seed-bearing trees are not cut unless there is a demand for the very thick bark on their trunks, when some of the trees which can be conveniently spared are scorified.

New season crop usually reaches Canton in the month of May. The yield of bark per acre is about 1,500lbs. per acre, but as the bark can only be obtained once every seven years, the profit after cutting, peeling, scraping, and packing, Chinese dues and rates, cost of freight, etc., cannot be a large one. Bark on old trees about ⅛ inch thick, burnt umber colour, and almost covered with lichens; bark on six years old trees and branches 1-16—1-12 inch thick lighter in colour than the older bark. Fruit very dark purple. The bark leaves, and incipient fruit—"buds" of commerce—taste strongly of cinnamon, the strongest taste being in the "buds" next the leaf peduncles, then the bark, and lastly the leaves. The older the bark, the more pungent the taste.

The best cassia is that which is thinnest, lightest coloured, and most like cinnamon in flavour. The small and broken pieces are the cheapest. Chinese Cassia bark is occasionally

adulterated with an inferior variety (*C. Burmanni*).

Calabar Cassia is also a rather inferior kind, darker in colour, thicker and coarser.

Annum Cassia, miscalled in the United States *Saigon Cassia* or *Saigon Cinnamon*, is really produced in the wildest parts of Annam, and not in Saigon (Cochin China). Very little is known about it, and there is no evidence of cultivation, and it is mere assumption that the tree is *Cinnamomum Cassia*. The bark, however, seems distinct enough from the cassia bark of South China. It occurs in straighter and smoother quills. It has none of the corky layer removed, but has a sweeter and more pungent taste than ordinary cassia, and most of this goes to the United States.

Ground Cassia is ordinarily made up as follows:—(1) Take 2 parts cassia lignea, 2 parts bale cassia, 1 part cassia buds, and 1 part wheat flour; (2) take equal parts of cassia lignea, bale cassia, and lignea vitæ sawdust. Ground cassia is occasionally adulterated with ground ginger.

Cassia Lignea is usually sold tied up in 1lb. bundles (which are not always packed the same inside as outside), and exported in half-picul cases, resembling tea chests and containing about 67lbs. each. Cheaper sorts are exported in bales.

Cassia is used in America and on the Continent for sweetmeats, chocolate, soups, and cooking purposes, and is taken largely with sugar and boiled rice, stewed fruits, etc. It also forms a staple in *Cassia Cakes*, and is used for mixing with rye bread—all on account of its sweet aromatic flavour; whilst here it forms the basis of ground spice, and is used for mixing with cattle foods.

Cassia bark reaches Canton and Hong Kong by steamer and junk. During 1896 the exports from Canton were:—

	Piculs.		*Taels.*
Cassia Lignea ...	3,333	value	33,432
,, Twigs ...	9,065	,,	6,040
,, Twig Bark	11,820	,,	25,457

and from Kowloon, during the same period:—

	Piculs.		*Taels.*
Cassia Lignea ...	70,138	value	490,966
,, Broken ...	3,676	,,	12,865
,, Twigs ...	2,386	,,	1,731

Thicker barks are distinguished by the Chinese as cinnamon, but Mr. Ford says this bark is simply the thick bark of very old (cassia) trees of the same species, and this is correct as regards the cinnamon produced in Kwangsi and Kwangtung. The latter province exports three times more cassia than the former.

The market town of *Ta-wu*, in the P'ingnan district, is the great centre of the trade, but there is a powerful "ring" in Canton that controls the whole business.

Cassia Oil. — Distilled from cassia leaves, buds, or bark, the former yielding about 1 per cent., but the latter scarcely so much. It has a sweet burning taste, with aromatic and fragrant flavour. When new it is of a golden yellow colour, but turns brown with age. It is considered a good specific for influenza. Often sold for oil of cinnamon, which it somewhat closely resembles. An inferior oil of cassia has also recently come into the market, which, although said to be pure, and having the external appearance and character of oil of the best quality, yet it contains only from 45 to 55 per cent. of cinnamic aldehyde instead of 85 to 95.

This aldehyde, being the most important constituent of cassia oil, should be made the main test of quality.

Cassis.—A French name for black currants, also for a home-made cordial, sirop, or liqueur, obtained by infusing the berries in brandy or other spirit for several months, and then sweetening and thickening the juice with sugar or glucose. The ordinary alcoholic strength is 25 to 28 per cent.; if more, the flavour is spoilt. It is a very popular drink with the people of Brittany; and most of the black currants

grown in France are used in this way, very few being made into jam or jelly. The Cassis de Dijon has a great reputation.

Caster Sugar. — See *Confectioners' Icing Sugar.*

Castile Soaps (pr. Cast-eel.) (also known as *Marseilles*, *Venetian*, or *Olive Oil Soaps*, and formerly called *Castle* or *Spanish Soap*) are either white, mottled, or powdered. They are usually superior and expensive kinds, first made hard with soda (cheap olive oil and water, or sometimes poppy, cotton, or other seed oil is added so as to render the product less hard). They are generally dry, inodorous, horny, and are pulverisable when warmed.

The *white*, which contains about 21 per cent. of water, is of a pale greyish white colour. This is said to be the purest, and is often used in medicine to form mild aperient pills. It should impart no oily stain to paper, and be free from rancid odour.

The mottled or marbled varieties are coarser and inferior to the white, contain more water, a larger proportion of free alkali, and a lower quality of fat. They are marked or veined by means of a small proportion of either iron, salts, or ultramarine being added to the boiled soap while in a semi-fluid state, and before it cools, merely to beautify them and gratify an old fancy (see *Mottled Soap*).

Powdered white Castile soap resembles wheat flour, and is often used in making furniture polishes, etc.

For any of these Soaps, apply to:— C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Castor. — A scent obtained from the secretions of the castor-beaver, but now almost obsolete in the perfume trade.

Castor Beans.—Same as *Castor Oil Nuts.*

Castor Oil. — F. *Huile de Ricin*; G. *Ricinusoe*; It. *Olio di Ricino*; Lat. *Ricini Oleum*; Sp. *Aceite de Ricino.*

A fixed oil obtained from the seeds or beans of the castor oil plant, *Palma Christi.*

It is now cultivated throughout India in two varieties.

In Egypt the bush attains the proportions of a small tree, and produces much oil, especially in Fayoum. Castor oil is commonly heavy, thick, and viscid, of a light amber colour, and with a somewhat nasty smell and sickening taste. It has a greater viscosity than any other oil; solidifies at about 18° F., and has a specific gravity of about ·969 at 12°. The seeds (called in Singhalese, "*Ameneka*") are first cleaned from the dust and capsules, then warmed to "blood heat," bruised between rollers, and then pressed cold in hempen bags. The oil which exudes is allowed to stand to settle, or it is clarified. This quality is of a fine light yellow colour, and called *cold-drawn* castor oil. A secondary quality is afterwards got by steaming the same seeds and again straining them. This product is then heated to 212° to separate the albumen and other impurities, but it remains greenish, is not so rich, and is liable to turn cloudy and to thicken in frosty weather. The cake or refuse remaining after expression of the oil is called "*pomace*," and is used in the manufacture of fertilisers. A bushel of seed, costing about 5/-, makes two gallons of refined oil, and the pressing costs about 1/- a bushel, and the oil realises 2/6 to 6/- a gallon. Like other vegetable oils, castor oil may be either partially bleached or completely decolourised by exposing it to the action of the sunlight, when it slowly becomes pale in colour and finally colourless. Several wholesale druggists have framework arranged outside the roof of their warehouses for this purpose. The oil must, however, be kept in stoppered bottles, for if exposed to the air the oil soon goes rancid.

Castor oil is liable to be adulterated with cheaper oils, such as croton, linseed, colza, cottonseed, poppy seed, and especially resin oil, which latter has a density higher even than castor oil.

Castor oil, both French, Italian, American, and East Indian, is extensively used as a most convenient and mild purgative, although, strange to say,

the actual purgative principles have not yet been identified with certainty, but are attributed to ricinolic acid and ricinelaidic acid. Dose, ½ oz. to 1 oz., often taken in water, gin, peppermint water, or weak lavender water. It is also used by dyers to fix colours; some 150,000 gallons are thus used in Scotland annually for Turkey-red dyeing. Nearly 2,000 tons of castor oil are imported yearly, about two-thirds from India and the rest chiefly from Italy. The lower qualities are used by soap makers in the manufacture of transparent soaps, and large quantities are used for lubricating purposes. As lubricants, castor oils are considered very good when judged by their viscosity alone, but the lower grades contain too much free acid, and are likely to cause greater corrosion of metal bearings. It is also used in the manufacture of Dutch cheese, butter, etc., and is frequently an adulterant of olive oil, 15 or 20 per cent. of castor oil in the latter not being recognisable by taste; in fact, strong, rancid olive oils appear to be sensibly improved by such an addition. Castor oil is imported chiefly from Bombay, in tins, barrels, hogsheads, and duppers, and classified as *Finest Tasteless*, *First Pressing*, *Second Pressing*, *Bleached*, *Yellow*, and *Seconds*. It is the best lamp oil they have in India, and gives an excellent white light, with but little soot—almost an imperceptible amount—which quality no other oils possess. The pure oil can be taken without tasting it by rinsing the mouth before and after with vinegar, and then chewing a coffee berry. Castor oil which has become acrimonious and nasty by long keeping may be greatly improved by mixing it in hot water, shaking well, and then, after it has stood a short time, pouring it off.

Importers and merchants.—F. Newbery & Sons, 27 and 28 Charterhouse Square, London, E.C.; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Castor Oil Nuts or **Beans.**—F. *Graines de Ricin*; G. *Purgiernüsse*; It. *Manteche*; Port. *Carrapatos*; Sp. *Catapucia Mayor*, *Chervas*.

These are the seeds or beans of the *Palma Christi* or castor oil plant (*Ricinus communis*). There are numerous varieties, but they may be classed under two main types. The *Palma Christi* is a tall bush or tree growing wild as a perennial about 30 feet high in the East Indies, and is often used as a hedge-plant. It yields large seeds with abundance of oil, but of inferior quality, whereas the cultivated plant is an annual, yielding smaller beans, but a finer quality of oil. It commences to yield beans about 10 months after the seed has been planted. In France it is also cutlivated as an ornamental plant in gardens, and around Nimes it is grown for its oil. The castor oil plant, although a native of East India, is now grown in most warm countries. Flies, and most insects, even locusts, as well as birds and the smaller animals, seem to have a real antipathy to this plant, and always avoid it as a pestilence. Large quantities are raised in Senegal and in the Western States of America, particularly Kansas, Illinois, and Missouri; St. Louis is a great centre for the beans, oil, and cake. The seeds are usually planted in rows or lines like Indian corn, about 2,000 plants to the acre, and these are grown six or ten feet high. The leaves are large and broad, but there is not much flower, and the smooth and marble-streaked beans or nuts which form in large clusters at the top of the plant grow three in a pod. An acre may yield 20 to 30 bushels, and each bushel will yield about 2 gallons of cold pressed oil (see *Castor Oil*).

In India the processes of extracting the oil are very primitive, but in Kansas City and Belleville, America, and some other places it is done by very powerful hydraulic machinery, the nuts being first carefully washed, and afterwards submitted to a pressure of 7,000lbs. to the square inch. The whole bean is never used medicinally, as it contains a poisonous element which has to be got rid of. (The name, castor oil nuts, is often wrongly applied to *Ground Nuts*.)

Castor Sugar.—Should be spelt *Caster* sugar.

Castoria.—A preparation of castor oil, widely advertised in America, and professedly inoffensive to the taste or smell.

Catalan Wine.—A wide term simply meaning any of the wines of Catalonia, in Spain, of which there are many cheap varieties, mostly red, and sold under different names. They may be had on the spot from 6d. a gallon upwards, and are mostly shipped from Barcelona to Tarragona.

Catawba Wines.—These are American products, both still and sparkling. Considered the choicest kind of wines made in the United States, and have been highly eulogised by Longfellow.

Cat Salt.—A name given by salt-workers to a very beautiful granulated kind of common salt. It is formed out of the bittern or leach-brine which runs from the salt when taken out of the pan. When the common salt is taken from the boiling pans it is put into long wooden troughs with holes bored at the bottom for the brine to drain out; under these troughs vessels are placed to receive this brine, and across them small sticks, to which the cat salt fixes itself in large and beautiful crystals. It contains some portion of the bitter, purging salt, is sharp and pungent, and is white when powdered, though pellucid in the mass. Large quantities of this salt are used in the manufacture of hard soap.

Catechu, Cutch, or Kuth.—The latter are native abbreviations of Catechu (pronounced Kat'-e-coo), a brown, inspissated extract from the wood, etc., of several species of the acacia plant in India; but in commerce, "*cutch*" is a superior quality, breaking freely like toffee, while "*catechu*" is a coarser and tougher kind, requiring to be chopped with an axe. It is used chiefly by dyers as a source of tannic acid, also in medicine as an astringent.

Catsup.—See *Ketchups*.

Cattle-foods.—(See also *Feeding Stuffs*.)—A typical cattle food (spiced) is made as follows:—6 cwts. locust bean meal, 10 cwts. Indian meal, 3 cwts. linseed-cake meal, 40lbs. sulphur, 40lbs. saltpetre, 30lbs. common salt, 20lbs. fenugreek, 10lbs. gentian, 5lbs. sulphate of iron, 4lbs. anise seed, 3lbs. ginger. All the ingredients should be of sound quality and finely powdered. Total, 20 cwts. 1 qr. 12lbs.

Cattle-spice.—The following are ordinary examples:—

(1) 16lbs. oil-cake; 1lb. each of gentian-root, liquorice-root, and fenugreek; ½lb. each of common ginger, nitre, aniseed, coriander-seed, and sulphur; ¼lb. Peruvian-bark. All are mixed thoroughly in a ground state, and the ground oil-cake added last.

(2) Equal parts of aniseed, ginger, liquorice, turmeric, and pimento. All ground and well mixed.

(3) 1lb. each of gentian root, cumin, fennel, anise, coriander, grains of paradise, African ginger, liquorice, dried sulphate of iron, flowers of sulphur, long pepper, carraways, fenugreek, and salt—all in coarse powder. Mix the above thoroughly with 7lbs. locust bean meal.

(4) 3lbs. carraway-seed, 6lbs. each of cumin seed and best turmeric, 1lb. common ginger. All ground and well mixed.

Apply to Roger Errington, Victoria Mills, Sunderland.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Cauliflower.—F. *Chou-Fleur*; G. *Blumenkohl*; It. *Cavolfiore*; Port. *Couveflôr*; Sp. *Coliflor*; W. *Cawl*.

A variety of the common kale or cabbage, identified as *Brassica oleracea*. The deformed inflorescence or head is only used. It is rich in albuminoids and phosphates, very nutritious, and much more tender than broccoli, with which it is often confounded, but the two are distinct. Cauliflower is easily injured by frost, whereas broccoli will endure a very hard winter. In England cauliflower is grown most in Cornwall, Devon, Channel Islands, and about

London, but for pickling purposes thousands of hogsheads of the heads come in saltwater from Holland *viâ* Amsterdam and Rotterdam every year.

Early cauliflowers arrive February to April from North of France and Channel Islands. French growths mostly come from St. Malo, near Cherbourg, large quantities being cultivated about Morlaix, Brest, and Roscoff, in Brittany, but the largest go to Paris.

The best have large white compact heads; any tinge of yellow or green indicates inferior quality. Small dark or soft spots betray age and decomposition, and are often cut off by the sellers.

Nearly all pickle-bottlers dye cauliflowers yellow with turmeric, which, however improving the colour, gives a nasty musty taste to the pickles.

For vegetables and pickles, apply to Allen Jeeves & Sons, Seddington, Sandy, Beds.

Caustic Soda (L. *Sodium hydrate*) is made by mixing crude carbonate soda with boiling water and then pouring on slaked lime.

Cavendish Tobacco or **Negro Head.**—An American production which has been softened and sweetened with molasses or syrup, and moulded into quadrangular cakes for chewing or smoking. The best is from the Virginian leaf, with or without flavourings, which is usually sweated a day or two to deepen the colour. Each of these compact masses is next separately wrapped in selected leaves, and is again pressed in powerful steam presses. *Cut cavendish* is the same tobacco cut into fine shreds.

Cavendish is imitated by English manufacturers, but this is generally very hot and bitter, also deficient in the aroma and flavour of the genuine American. This is accounted for by the limited choice of first-class leaf, so essential in producing fine light coloured kinds of cavendish. *Black cavendish* or *Negro-head*, like spun tobacco, affords a disguise for all kinds of stuff—good and bad.

Caviare (pr. *cav'-yar*). — Da. *Caviar;* Du. *Kaviaar;* F. *Caviar;* G. and Sw. *Kaviar;* It. *Caviale;* Port. *Ovas escaladas;* Rus. *Ikra;* Sp. *Caviario, Cabial.* (See also *Botargo.*)

A condiment largely used by rich and poor in Russia. It is prepared from the dried spawn or salted roe of fish. The genuine is made from the roe of the sturgeon, especially the white sterlet species, a single fish yielding as much as 120*lbs.* of roe. It is, indeed, the chief product of the *Accipenser huso.* A cheaper and less prized red kind is from the grey mullet, or some of the carp species.

Caviare in its finest condition is grey, pearly, succulent, and delicate; but most of that met with in England is black, herring-flavoured, and small-seeded. It is as different from the article in Moscow as is a shadow from the substance.

The roes are first washed in vinegar, and then salted. Sometimes they are put into a bag with a strong brine and pressed by wringing, then dried, and put into casks or cisterns perforated at the bottom, where they are pressed by heavy weights. The inferior sorts are often trodden with the feet.

In the Volga district the white sturgeon leads for the high quality of its roe, and next comes the common sturgeon.

When a stranger is admitted into the fishing section where Caviare is prepared, he finds it supplied with a number of troughs, wooden tubs, and vats, and a stand looking like a bench, with upper frame open, on which is placed the freshly salted caviare in order to separate it from the superfluous brine. There is also a very important implement—the caviare press—with which the "pressed caviare" is prepared. On the walls hang the caviare sieves or wooden frames and nets of strong cord.

The workmen separate the caviare from the egg bags in which it is enclosed, by rubbing it with the hand through a sieve into a vat. The egg skin does not go through, but remains on the surface of the sieve. When fish are in the first

stage of decomposition, the egg skins get so fatty that they cannot be separated from the roe, and from these the low grades of caviare are made.

Next is the salting of the caviare. It is salted only with brine made of fine salt, which is carried in bags all the way from the Lake of Bardymkul, in the neighbourhood of Chodjent, in Ferghana, Turkestan. This salt is obtained by dynamite explosion, and is of superior quality to any salt produced in England. The difference in "fresh" caviare is caused by the smaller or greater quantities of salt contained in the brine, and this is regulated to meet the length of time the caviare is intended to be kept. The fresh brine is kept in large wooden tubs, and the fine clean salt used for the preparation of the brine is put into small bast barrels. The superfluous brine is used again. Immediately after the eggs have been rubbed through the sieves, they are put through the brine, and, as soon as they are deprived of the superfluous brine, they are put into tin jars or cans and small wooden kegs; and the so-called "fresh caviare," which is high-priced, is ready for market. The cheaper kind is first cured in the brine, then put into linen bags and pressed. This is called "pressed caviare."

A large trade in caviare is carried on on the Caspian Sea, the Volga, and its affluents, over a million pounds being exported annually from Taganrog and Astrakan. The greater part of it goes to Turkey, Greece, Italy, and Germany; only a little to England, and still less to France.

A good deal of both lake and river caviare, salted with German salt, is now prepared in the United States and Canada, chiefly at the Delaware River, Georgetown, Chesapeake Bay, the Fraser and Columbia Rivers, Lake Superior, and the Lake of the Woods; these makes are largely exported to Germany, through Hamburg. Some 4,000 or 5,000 kegs of about 140lbs. each are shipped yearly, nearly half of the export being consumed in the cheap restaurants of Berlin, and the finer quality in Austria, Italy, England, and other European countries.

The Lake caviare is preferred to that from the rivers, on account of its larger roe, the latter being small and black in the river caviare. The Lake of the Woods has a total area of over 6,000 square miles, and its waters abound with fish of all kinds. The most important fish in the lake are the sturgeon, and it is these to which the fishermen devote the most attention, but it is feared that unless measures are taken soon to reduce the take the fish will be exterminated, so far as commercial purposes are concerned.

After the fish is killed and the head cut off it is carefully cleaned, the roe being set aside in tanks. When the catch has been disposed of, the roe is then taken and washed repeatedly until it is thoroughly clean, after which it is rubbed by hand through a series of screens until all the eggs are separated. That is all the process necessary. It is packed in the kegs, and kept in cold storage until the time for shipment arrives, when it is sent to London and to Germany. A number of experiments have been made with Canadian and American salts, but so far they have not proved so good as the salt brought from over the ocean. On arriving in Europe the kegs are opened, and the caviare is sorted out according to quality. It is then put up in small lead packages and tins and sold as Russian caviare. The inferior portion is often reshipped to America, where the appetite for caviare is not so exacting. In Germany the use of the Canadian product is increasing, while the supplies of the Elbe and Vistula are decreasing.

Holland also exports a little caviare, but the quality is poor.

Caviare is prepared in two ways for export from Russia.

In making *Caviar grénu* the eggs are cleaned in water to remove the outer covering, and are then left in strong brine for about 45 minutes, which is afterwards drained off.

In preparing *Caviar compact* the eggs are separated from the skin veins, etc., and then salted in a trough and left about 45 minutes in brine; but, while

there, they are kneaded in order to soften them, after which, instead of being left to drain slowly, they are twisted in cloth bags, and, finally, heaped lightly into small wooden barrels ready for delivery.

A third method consists in preserving the eggs just as they are taken from the fish, and, after lying for seven or eight months in brine, they are dried in the sun. This is a coarser kind of caviare, but largely exported.

Large quantities are made in Cura, where the people dry it in front of their houses, the smell attracting such swarms of flies that the air seems alive with them. Thousands of tons are made annually, but it is oily and not considered very digestible, and, as it is generally in a state of decomposition, it can scarcely be wholesome.

Caviare is occasionally eaten as a delicacy in this country, and, even in Shakespeare's time, it was known to a few, but not relished by many. Hence, Hamlet says of a certain play, "'Twas caviare to the general," *i.e.*, to the common people, who could not relish nor understand it. It is sold in small glass barrels and in tins, but the best is packed in small kegs, and the inferior in dry cakes.

The savoury and piquant taste of caviare, as well as its suitability for use as *hors d'œuvres*, sandwiches, and for various culinary preparations is in some countries one of the most appreciated preserves among *gourmets*.

True Russian caviare is easily distinguished by the superiority of its quality, the delicacy and freshness of the "grain," which is very loose, while British or German caviares are only a species of pulp (*bouilli*) which has lost nearly all its aroma.

The relish for caviare has to be acquired, for when first tasted it is very disagreeable, so it is only occasionally eaten as a delicacy by English people. A popular way of serving it is to spread it on dry toast, on slices of brown bread and butter, or on French roll or Vienna bread, and it is sometimes garnished with watercresses, or a little lemon juice may be squeezed over it. A person rarely consumes over half an ounce or so at once.

Cayenne Essence is prepared in various ways:—

(1) ½ oz. of cayenne and ½ pint of brandy digested 10 or 14 days and then filtered.

(2) 3lbs. of bruised cayenne pods and 1 gallon of rectified spirit. Digest 14 days, express the tincture and filter. Distil off one half, add 15lbs. of dry salt, mix, dry, and rub through a sieve, and finally fill in warm dry bottles. It is often coloured with a little vermilion or rouge.

Capsaicin, the active principle of cayenne, is so very pungent that even half a grain diffused throughout a room will set a whole party of people sneezing.

Cayenne or Guinea Pepper.—(See also *Capsicums*, *Chillies*, *Nepaul Pepper*, *Paprika*, etc.)—An extremely pungent and fiery kind of spice, originally from the island of Cayenne, but now grown in all hot countries, and largely employed for culinary purposes. It consists of the powdered pods and seeds of different species of capsicums, which are of all sizes and quite numerous, but principally of *C. minimum*, *C. baccatum*, and *C. frutescens*.

It ought to be remembered that cayenne is not really pepper at all in a true sense, the plant not being one of the *piperaceæ*.

C. frutescens, also known as Guinea Pepper or Red Pepper, yields the best sort. The pods of this species are small, scarcely an inch in length, very narrow, and of orange-red colour. They are somewhat hotter than the first-mentioned variety and aromatic, which the others are not. A quantity of this species is also cultivated around Salonica, and especially in the Canton of Karadja Abad, about Vardar Yenidje, and Vedine, in Turkey. The plant here seems to prefer a sandy and humid soil, and it grows sometimes almost in the water. Harvesting commences only when the plants are entirely red. The first gathering is the best, and the last

the worst, as the peppers redden imperfectly in the autumn.

The ruddy tint of fresh-grown capsicums soon dulls and becomes unattractive when ground and exposed to light; hence, ground cayenne, when genuine, is very dingy in appearance, and whoever chooses it from its ruddy fresh tint makes a great mistake. It is then almost sure to be contaminated, perhaps with red lead, or perhaps, worse still, with sulphuret of mercury. Red brick-dust, salt, saw-dust, mustard-cake, rice, red ochre, and turmeric have all been found in ground cayenne.

Ground cayenne if heated strongly volatilises a very acrid vapour (due to *capsaicin*) causing intense irritation of the throat. This sensation can be produced by so small a portion of cayenne that any foreign substance mixed with it can in this way be detected. It is only necessary to separate carefully, by the aid of the microscope and a camel-hair brush, all particles of cayenne, and heat the portion suspected; if no acrid vapours arise it is not cayenne. The crystalline alkaloid, called capsaicin, does not exist in the seed, but in the pericarp. The oil is called *capsicol* or *capsicin*.

Cayenne greatly improves the flavour of various foods and assists the digestion, but both this and all other hot peppers if used too frequently become injurious and induce dyspepsia. The small seeds inside the cayenne pod, or the pods themselves fed to canaries will turn the feathers from pale yellow to deep gold colour.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

Cayenne, Soluble.—Used as a condiment, and is prepared by adding the strong tincture of cayenne (see *Cayenne Essence*) to common salt. The solution is then evaporated until a portion of it, on cooling, crystallises.

A little saffron, or annatto, or rouge, is generally added to improve the colour of the product, which is quite soluble, and retains the pungent taste of the cayenne.

Cedratur.—(See also *Citrons.*)—A species of citron, *Citrus medica*, growing abundantly in Corsica, Sardinia, Sicily, Madeira, and the Azores. The fruit has the shape of a pear, but is very much larger, and has a very thick and tough rind. This rind, when candied, commonly goes by the name of "Citron peel," although over double the size of other citrons, and often weighing 5lbs. to 10lbs. each. The peel is very rich in essential oil. Four different products are obtained from the cedratur, namely:—(1) The candied peel, mainly sold by grocers at Christmas time. (2) A preserve made by cutting the fruit into small pieces, and boiling in sugar like jam or marmalade. (3) A liqueur prepared by macerating the fruit in alcohol and the addition of syrup. (4) An essential oil largely employed in perfumery.

Celery and Cerleriac.—F. *Céléri*; G. *Sellerie*; Port. *Celeria*; Sp. *Apio*; W. *Bwyd-lysiau*.

An umbelliferous plant (*Apium graveolens*), a relative of the parsley family, native of Europe, and long cultivated in gardens for the use of the table. Perhaps the largest and finest is grown about Manchester.

The green leaves and stalks of the upright or Italian are used for flavouring soups, and the lower stems are blanched in the ground by packing the earth around them nearly to the leaves as soon as they begin to droop. Another way of blanching celery is by binding rough strong paper on to the heads; this method prevents the outer leaves being disfigured by slugs, and also permits of liquid manure being freely used. There are several varieties, pink, yellow, and white stemmed. *Celeriac* is the name given to a large and turnip-rooted variety. *Wild celery*, growing in ditches and on the sea coasts, is said to contain a dangerous narcotic poison.

Celery is in season during winter and spring, and will keep some time after gathering; it may be kept several months by putting it in boxes filled with earth

and storing them in a cellar. Celery is often much damaged by the larvæ of the "celery-stem fly," and a fungus known as "red rust," and "black mildew."

It should be chosen creamy-white in colour, large, crisp, solid, and nutty in flavour. Celery has long been considered an excellent remedy externally as well as internally for rheumatism.

Celery-seed in bottles is a salable commodity used for flavouring soups, but henbane seed, which is very poisonous, has been found in some preparations.

Celery oil. A new industry in Germany, is the manufacture of a strong aromatic oil from the leaves of the celery plant. This is used as a flavouring. One hundred pounds of leaves makes one pound of oil.

Celery Coffee. — See *Coffee Substitutes.*

Celery Essence.—This is made:—

(1) By digesting celery seeds in spirit for a week or ten days, and then filtering.

(2) 2 drachms oil of celery, ½ oz. carb. of magnesia, 1 oz. sugar, 8 ozs. cologne spirit, and 8 ozs. of water. Dissolve the oil in a little of the spirit, and rub in a mortar with the addition of the magnesia, then add the sugar, and colour slightly with tincture of grass.

Cement for Bicycle Tyres.—See *Bicycle Tyre Cement.*

Cement for Glass, Marble, Porcelain, and Crystal, is made of powdered glass and white of egg. Glass, in the finest powder, is mixed to the desired consistence with white of egg. Broken articles joined with this cement set so hard that they may be broken again in another part, but not where first cemented.

Cement for Jar Lids. — A good cement for fastening lids on jars is made from 4½lbs. plaster-of-Paris, 3lbs. common resin, and 1lb. caustic soda. Melt the resin and soda in hot water, and stir in the plaster-of-Paris when wanted for use. Another—Melt and mix 1lb. of resin and 1lb. of tallow. See that the lids are quite dry before sealing them on the jars. The compound sets in an hour, adheres strongly, is not permeable like plaster used alone, and is attacked only slightly by warm water.

Cement for Jewellery, etc. — Regularly used by jewellers, and known as diamond cement. It is made of gum mastic and isinglass dissolved in spirits of wine.

Cement for Rubber and Metal.—A good one is made by dissolving pulverised shellac in ten times its weight of pure ammonia. It should stand three days before use.

Cements, various.—(See also *Portland Cement.*)—Many kinds of cement are used for repairing broken glass, china, and earthenware. They are mostly made of Canada balsam, shellac, copal or mastic varnish, isinglass, india-rubber, etc. Isinglass, mixed with glue, makes a very strong cement for glass, porcelain, etc.

Melt together 2lbs. shellac and 1lb. Venice turpentine, and form into sticks of size and shape desired.

The white of an egg mixed with a little quicklime makes a useful cement for crockery.

Apply to E. Mitchell & Sons (makers of "Stick-fast" for Crockery), 5 Burnet Place, Bradford, Yorks.

Gardner's patent "Rapid" Sifter and Mixer, freely used for cements. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Century Plant.—See *Pulque.*

Cepes or Ceps.—A large species of mushroom common in France, around Perigord and Bordeaux.

The edible species, "Bolet-Cepe" or "Cep blanc," is *Boletus edulis;* but the "Cepe noir," *B. æreus,* is a poisonous species; and the "Cepe faux" is *B. luridus.* There is no known method of cultivating them, but "Cepes au Naturel" and "Cepes a l'huile" (pickled in olive oil), as well as Dried Cepes, are very popular with the French, and are usually sold in glass bottles or 1lb. tins at about 12/- and 18/- per doz.

Cerasin. —That portion of cherry-tree gum which will not dissolve in water.

Cereal Foods. — See *Prepared Foods.*

Cerealine. — A nitrogenous substance obtained from bran, closely resembling diastase in its power of transforming starch into dextrine sugar and lactic acid.

It is largely used by confectioners, bakers, etc. Wholesale price, 14/- to 15/- per cwt.

Cerisine or **Purified Ozokerit.**— F. *Cérésin;* G. *Erdwachs;* It. and Sp. *Ceresina.*

An artificial waxy composition, melting point 61° to 78° C. Used for making candles (see *Ozokerit*). Sometimes this mineral is artificially coloured to imitate beeswax.

Cerulean Blue.—Is properly a pigment composed of the oxides of tin and cobalt, and has the peculiar property of retaining its blue colour by artificial light.

Cette Wines.—The town and port of Cette, in the department of Herault, France, is situate on a neck of land between the Mediterranean Sea and the lagoon of Thau. It is notorious for the manufacture and exportation of imitation wines, such as Madeira, Malaga, Alicante, Chypre, Malvoisie, and others foreign to France, and these fabrications are known in commerce as "*Cette Wines.*"

Ceylon Coffee.—Ceylon coffees are largely imported into this country, but are often highly objectionable to those who have really a knowledge of what fine coffee ought to be.

Some Ceylon plantation coffees, however, are popular. They come into our markets about Christmas. These berries are very smooth, of a palish green colour, and of uniform purity, with good flavour.

Ceylon or **Jaffna Moss.**—A species of edible sea-weed, *Sphæroccus lichenoides*, native of the Indian Ocean.

It was introduced to European notice by O'Shaughnessy about 1835, and is now used as a demulcent food-jelly for invalids.

It is said to consist of 54¾ per cent. of mucilage, 15 per cent. of starch, and 7 per cent. of salts. Half an ounce boiled for about half an hour in a quart of water forms a jelly, to which wine, milk, sugar, and flavourings may be added as desired.

Ceylon is a pear-shaped island at the South of India. It is not quite so large as Ireland, but has a population of something over three millions, the Europeans numbering only about 5,000. It is very curious and remarkable how the letter *C* preponderates as an initial in all that relates to Ceylon, not only in the names of places, but in articles of produce and other things.

Ceylon Tea. — (See also *Teas, Blended Teas,* etc.)—Ceylon Teas may be said to date from 1876, when the coffee leaf disease in Ceylon induced planters to give serious attention to cocoa, cinchona, cardamoms, and finally to tea; for, although tea had been tried before both by the English and the Dutch, it is only since 1876 that it has developed so marvellously, rising as a phœnix from the ashes of the ruined coffee plantations. In the year 1880 only about 100,000lbs. were used in this country, and in 1885 3,217,000lbs., but in 1886 the consumption had risen to 6,245,000lbs., in 1887 to 9,941,000lbs., in 1888 to 18,533,000lbs., in 1889 to 28,508,000lbs., and in 1890 to 34,516,469lbs., till in 1899 the total export reached about 125,000,000lbs.

Ceylon Tea.—How produced. Tea is now the chief staple of the island, the plant flourishing everywhere from sea-level districts to the summits of hills 7,000 feet high. The plant will grow to 20 feet high, but is kept down to 3 feet high by pruning.

As a rule, the light, tippy teas (thin, and without much sap) are obtained from the young shoots, after pruning. After a field has been pruned, the bushes produce very poor teas for some time. In order to obtain a big yield, it has been

the fashion, of late years, to prune heavily—say, every two years, instead of every three or four, as previously. This produces a big yield, but the quality of the tea suffers in consequence. The best leaf is obtained from a bush that has not been pruned for some time.

Plucking is carried on continuously, not as in China, periodically. The bud and two young and tender leaves only are taken. The teas are dried under cover and not in the open air. The manufacture is as follows:—First, the fresh, green "leaf" is brought into the factory by coolies, spread out on long canvas shelves, called "tats," and allowed to "wither," or slightly dry, at the air temperature for some 48 hours. Secondly, the "withered" leaf is "rolled" in a machine-roller for an hour or so. During this operation the vegetable tissues are thoroughly crushed into a moist and juicy condition, and each leaf assumes a more or less cylindrical form. Thirdly, the "rolled" leaf is allowed to ferment in trays for a short time. Much depends on the proper regulation of this stage, because important changes take place during fermentation. Fourthly, the fermented leaf is re-rolled, and then "fired," that is, submitted to the action of a current of hot, dry air (at about 210° F.) for a certain time.

The tea is now in a manufactured state, and has only to be sorted into the different grades, and put into large bins, until enough has been collected to make a "break." Loss of weight from the green leaf to the made tea is from 75 to 78 per cent.

The characteristic of the beverage produced from tea grown in the lowlands is its "strength," and that of high-grown tea delicacy of flavour. In fact, nearly all this elevated land has now been taken up.

The plants mostly cultivated are from fine jats of Indian seed, and, owing to the soil, these yield great pungency and high flavour.

The trees do not come into full bearing until seven or eight years old; but when once planted they last many years.

Ceylon tea possesses the good qualities of both Chinese and Indian teas, and, therefore, does not need any blending, and it is probably owing to this remarkable fact that Ceylon tea has risen so rapidly in favour.

The quality of the tea produced from any particular garden can be kept pretty nearly the same as regards flavour and strength; but, of course, when the monsoon breaks there is no doubt that the tea from all gardens has not the same flavour or strength. This, however, is only for a very brief period, and is common to all the gardens, for rain-falling, after dry weather, brings on a very quick flush, and then planters have such a rush of leaf coming into their factories at once, and not having time or space to prepare it all properly, teas are often sent away carelessly rolled or sorted, and under-fired.

The keeping properties of Ceylon tea are not very good, and it deteriorates rapidly on exposure to the air, whether from being grown in a damp climate or manufactured in a different way to the Chinese seems uncertain. But the growers are making considerable headway, and owing to the personal supervision which they exercise over their plantations, to the use of machinery, and to the fewness of middlemen between producer and consumer, it is used very quickly, and before losing much of its virtue.

The names of the gardens in Ceylon are legion, but the most popular teas come from the Newera Eliya district, about 5,000 feet above sea level. It may be taken as a general fact that the higher the elevation at which Ceylon teas are grown, the better the flavour. Perhaps the four best gardens are Pedro and Monkswood, sold in Colombo; and Norwood and St. Leonard's, sold in London. Ceylon growths are more delicate as a class than Indians.

Tea planters, however, are not all "experts." Their teas are often wrongly marked, through the growers not knowing the difference between one grade and another. The teas are, in fact, frequently marked at random, and are

given high-sounding names that do not properly belong to them. Other growers lack the necessary appliances for properly preparing their teas.

Cheesiness.—The disagreeable, malodorous taint in some Ceylon and also Indian teas, recalling that of rancid cheese, is owing to green, sappy, immature or unsuitable timber being used in making the chests.

And who gets these cheesy teas? Not the large blending firms (they are too wide-awake), but the retailer, who buys small lots of unblended teas. A little of this cheesy tea will spoil a large mixing, and do irreparable damage to a family trade. (See "Blended Teas.")

Some of the growers really know very little of the quality of tea, and often send away their crop of leaves to be "made up" and packed by others. It is from Ceylon that certain fancy selections of tea, consisting of the extreme ends or "tips" of the small shoots, have occasionally been imported in small parcels, and have fetched fancy prices. In May, 1891, a small quantity from the Gartmore Estate was reported to be sold in Mincing Lane at £25 10s. per lb.; another from the Havilland Estate at £17 per lb., and in March of the same year a selection from the Gartmore was sold at £10 2s. 6d. per lb. These unique teas were of the brightest gold colour, blazing with tip, and resembling grains of gold. There is no special season for the arrival of Ceylon teas, they are coming forward all through the year; but, perhaps, the best comes down from about September to December, although the autumnal flavour is not apparent with Ceylons as with Indians, and the average prices are from 8d. to 1/3 per lb. in bond. Chests hold about 94lbs., half chests 50lbs., and boxes 18lbs.

Wholesale Dealers and Importers.—Jackson Bros. & Co., 14 St. Dunstan's Hill, London, E.C.; Spencer, Turner, & Boldero, Lisson Grove, London (see *High Caste Ceylon* and *Silver Packet Teas*).

Chablis (Wine).—One of the most popular white wines from the Burgundy district of France. It takes its name from the town of Chablis, in the canton of Yonne (Auxerre).

Somewhat more spirituous and more highly flavoured than the red wines of that locality; but the highest type of French *white* wine. (See *Burgundy Wines*).

Chalk.—F. *Craie, Blanc de Meudon;* G. *Kreide;* It. *Gesso;* Port. *Crida;* Lat. *Calcium Carbonate;* Rus. *Nigel;* Sp. *Yesso;* W. *Cialc.*

A soft, white, rocky limestone, or carbonate of lime, made up of microscopical small shells, etc. It forms part of the cliffs in the South and South-East of England, and on the opposite coast of France; also found at Meudon, and Montmartre, near Paris, and in Champagne, but nowhere else. It is 600 to 800 feet thick under the City of London. When crushed, washed, and purified it becomes *Whiting, Spanish White, Paris White*, etc. Several hard kinds of clay are called chalk, such as *Red Chalk* or *Raddle, Yellow Chalk*, etc. *French Chalk* is a scaly kind of talc or soapstone, largely used by tailors for marking cloth. *Black Chalks* are made from charcoal and from lamp-black, black-slate, etc. *Spanish Chalk* is a variety of soapstone obtained from Aragon in Spain.

The best chalk contains no flinty matter, arsenic, nor magnesia.

Chamboureau Wine.—This celebrated French wine, the best known of all the wines in the lovely Anjou district, is the product of the Chamboureau Vineyard, near Savennieres, Maine et Loire, France, also near the "Coulee de Serrant" and the "Rocheaux Moines" Vineyards, and is now the property of Monsieur Jules Chatillon, who gained considerable renown in the defence of Paris during the Franco-German war of 1870. This enterprising gentleman has lately replanted the whole of the vineyard, regardless of expense.

Chamois Leather or Skins (also called *Wash Leather* or *Shammy Leather*).—Dan. *Semslæder;* Du. *Zeem Zeemleêr;* F. *Peau de Chamois;* It *Camoscio;* Ger. *Sämischleder;* Port

Camirça; Rus. *Samschnüi, Koshi;* Sp. *Gamiuza;* W. *Math o lwdn gafr.*

Originally prepared from the skin of the Chamois goat; but the skins of sheep, kids, or common goats are now generally substituted.

"Kips," a name in India for young cows or oxen, is a term among tanners for the skins of *young* animals; although many "kips" are really prepared from the hides of full grown animals of small breed, in fact, any skins under 25lbs. weight. The skins are thoroughly impregnated with fish-oil, then hung on a line, and submitted to several severe scrapings on both sides, when, on being dried, it assumes its peculiar softness and pliancy, and can afterwards be washed with soap and water without losing its colour. Another method of treating the flesh side of sheep skins is to soak them in lime-water and in a solution of sulphuric acid. Crude fish oil is then poured over them, and they are afterwards carefully washed in a solution of potash. "Chamois leather" serves many useful purposes—cleaning glass, plate, polishing brasses, dusting, etc. Gauntleted gloves and other underclothing, linings of gold-miners' bags, coverings for whip handles, etc., are often made of this kind of leather.

It may be cleaned in a weak solution of soda in warm water. Rub plenty of yellow soap into the leather, and allow it to soak for two hours. Then rub it well until it is quite clean, and rinse it well in a weak solution composed of soda, soap, and warm water. If rinsed in water only, it becomes hard when dry and unfit for use. After rinsing, wring it well in a coarse towel, and dry quickly, then pull it about and brush it well, and it will become softer and better than most new leathers. The flexibility may also be restored by washing in strong suds made of olive oil and potash with a little water, and afterwards laying it between brown paper wet with glycerine.

Chamomile or **Camomile.** — Fr. *Camomille;* Ger. *Romische Kamillen;* It. *Camomilla;* Port. *Manzanilha;* Sp. *Manzanilla.*

A low creeping composite plant, *Anthemis nobilis,* well known throughout Europe, with strongly scented leaves. The single flowering variety are in high repute, as being more odoriferous and yielding a larger proportion of volatile oil, also as affording a bitter stomachic and tonic; while the double variety produces the common chamomile flowers used for medicinal purposes. The plants require a poor, dry soil, otherwise they are less powerful in their medicinal qualities. They are largely cultivated about Mitcham in Surrey, and considerable quantities are yearly imported from Persia, etc.

Oil of Chamomile is distilled from the flowers. It is of yellow colour and strong odour, with very nauseous taste, but is considered a valuable stimulant and anti-spasmodic. Dose—1 to 5 drops.

Chamomile Tea.—A beverage recommended by Dr. Hood for the use of gouty or dyspeptic sufferers. Infuse 12 chamomile flowers, and a saltspoonful each of grated dry lemon-peel and grated ginger, in a pint of boiling water. Serve from a teapot into teacups as usual.

Champagnes.—These wines are distinguished, according to the site of the vineyards, as river or mountain growths, the former being for the most part "*white,*" the latter "*red.*" The French districts comprehend the departments of Aube, Ardennes, Marne, and Haut Marne. The best wines are grown at a medium elevation upon the hills, for low and soft grounds only produce the very lightest wines of any sort.

The vines are cut down almost to the ground every winter, and the new shoots are never allowed to exceed a height of about 2 feet to 3 feet, it being impossible, without destroying the quality of the wine, to assist or force the plants with much manuring. Only a limited number of bunches of fruit are left to come to maturity, and the grapes are not much larger than good-sized peas or currants, but they contain the purest and the richest blood of the vine.

The Marne vineyards produce the most esteemed, those in the neighbourhood of Rheims and Epernay are the most famous of them. Epernay is, in fact, the headquarters of champagne. A vast subterranean city of wine, the whole town is honeycombed with underground galleries—dark, damp, and cold—for the tens of millions of bottles of this exhilarating beverage. The cellarage alone of one firm (Moet and Chandon) is said to be five miles in extent, all cut out of rock, and containing on an average some 5,000,000 bottles of wine, and others are equally large. The Champagnes produced at Rheims, however, fetch the highest prices, and Messrs. Heidsieck & Co. (of *Dry Monopole* fame) have quite six miles of cellarage, often with six million bottles of champagne in stock. Champagnes are mostly named after the makers. In the beginning champagne is simply white wine of any kind. The wine presses in September are in daily operation, and casks full of the precious juice are being stored on the ground floor of the warehouses. Fermentation continues till the appearance of the first frosts. The wine is then drawn off, to free it from the dregs or lees, and put into tuns, or "foudres," containing about 5,000 bottles each. This stage develops one of the most delicate and important operations in the manufacture of champagne, as in the foudres the different "*cuvées*" are mingled. Nothing is added to it. But, on the other hand, nothing is taken away from it, as is the case with *still* wines. (*Still* wines are poured off, three or four times, into other casks, to free them from the sediment which always forms in wine.) It is just this sediment which develops sugar and carbonic acid gas, that, remaining in the wine, makes it champagne. The champagne then lies in its cask for a year, or sometimes two years. On the judicious blending of the different wines composing the "cuvee," or, in other words, those which are mixed in the same "foudre," very much of the good quality of the wine depends. They must be mixed so as to assimilate, as nearly as possible, both in shade and bouquet, and when this is skilfully effected they will ripen together and mutually aid each other. The houses that have gained the highest reputation for their wines are those which have paid the greatest attention to this part of the process. Sometimes it is mixed with some of the next year's wine of the same character, sometimes not. Finally, sediment and all, it is bottled, and the bottles are stacked, lying on their sides, in great frames. The upper side of each bottle is marked with a dab of white paint, and the bottles are turned a little way round every few days.

It can be easily seen by the white mark when a complete revolution has been made. This is done so that the sediment may not all collect in one place. There is also another and a more drastic process for shaking the sediment about. We hear a loud, hollow, rhythmical reverberating noise. Our guide takes us round a corner, and there we see a row of six men, their faces covered with black wire masks, a bottle held by the neck in each of their hands. With military precision they follow their leader. "One," he cries, and bang, bang, bang, bang, they all hammer their bottles on the board in front of them. "Two," and all the bottles are raised in the air, and waved backwards and forwards. "Three," and the men change their hold from the neck to the body of the bottle, and bang, bang, bang, bang, go the other ends on the board. It looks and sounds as if every bottle must be smashed to pieces. As a matter of fact, few break. The wire masks are to prevent these from flying in the men's faces.

When the wine has been lying long enough, and all the thick part has gathered against the cork (for the bottles are tipped a little to allow of this), the cork is taken out, and the wine in the neck of the bottle, containing the sediment, flies out. The bottles are then handed on to a man, who, with a very ingenious machine, by which several bottles can be worked at once, adds to the wine a little sweet liqueur, to replace the sugar which has shot out in the sediment and to suit different tastes. For the driest champagne only 1 per cent. of liqueur is added; for the sweetest, 12

per cent. The bottles then go to the corker, who, with another ingenious little machine, drives in tremendous corks as large round as a child's fist. He then passes them to the wirer, who, with a third machine, wires down the corks at the rate of one hundred an hour. The bottles are then provided with a necklace of gold or silver foil, and the champagne is finished.

It is, however, inconvenient here to detail fully every operation it undergoes in the cellars, the disgorging room, the bottling room, the packing warehouse with its labelling and papering process, but it is all necessary to obtain a thorough and practical knowledge from the vineyards until we have it on our table in England, which really means about three years from the vintage day till the day we receive it. It must be understood that the champagne is really green even then, and ought to be kept at least another two years before it is in good drinking order, and this is, to a great extent, the reason why good champagne is so dear.

Sillery is so called after the old vineyard of that name. Of the numerous Champagne houses, that of Mercier & Co. is, however, the largest, and the immense caves are cut in pure chalk rocks without any masonry.

The wines of Ay are sparkling, bright, and possess a pineapple aroma. Those of Mareuil, Hautvilliers, Pierry, and the choice red growths of Verzy, Verzenay, Bousy, etc., are much sought after by connoisseurs all over the world; but the other red mountain champagnes are, on the whole, less esteemed than the white. There seems to be a growing demand or preference for "dry" champagnes. A *dry* champagne must be a good wine, or its acidity would be detected at once; but this defect would be hidden by the liqueur necessary to make it sweet; hence, a sweet champagne may be made of almost any quality of wine, however sour or thin.

Sparkling Champagne. — *Grand Mousseux* is the result of incomplete fermentation; it is, of course, the brightest and most captivating, but not the choicest, and lacks the peculiar *bouquet* which makes the creaming or slightly sparkling wine, *Crêmans*, or *Demi-Mousseux*. The class most esteemed by connoisseurs is the "still," so called by reason of its being bottled after the fermentation has ceased. The terms *Cuvée* and *Sec* are often used in connection with champagne; *sec* means dry, and a *cuvée* is a large tub or vat; hence, it signifies a superior tub or vat of grape juice. Champagne is often recommended by the faculty for keeping up the system during exhaustion. It stimulates without subsequent depression, the carbonic acid carrying off the effect of the spirit. Bad or fictitious champagnes are often very injurious to health, and the brands or names of the best makers are closely imitated. A good test of quality is the rapidity with which it throws down its head in a tall glass. It is a mistake to drink it while effervescing. The production of cider in France is about 700,000,000 gallons a year, and it is pretty certain a great amount of this is made into champagne. Indeed, it is said—but there are some people who will say anything—that a great portion of the champagne drunk in this country is made from sugar and green gooseberries, or from rhubarb. Champagnes contain only about 12½ per cent. of alcohol.

Elba Champagne is a recent production of the vine-growers in that island. It is a more robust and ferruginous wine than the French, but, so far, is too recent an experiment to have the delicacy and fineness of taste which age gives to the latter, although it has many admirers, and has obtained medals in several countries.

Sparkling Saumur or *Saumur Mousseux* is often labelled "Saumur Champagne," but this is wrong, and not being a champagne the British Government will no longer admit it under the title of champagne.

All champagnes do not froth, and the best are generally those which only froth slightly. Where there is much froth there is much waste of the better qualities of the wine by evaporation.

Occasionally odd bottles of good brands are found flat and insipid on uncorking; this is usually the result of shrinking corks, which are often too short. The champagne vintage of France averages 20,000,000 bottles, of which about 17,000,000 are exported.

The name Champagne has recently been made a regional appellation, and under no pretext is it to be allowed as a generic term. Hitherto it has also been largely manufactured, in Germany especially, from early and late Burgundy and Klebroth grapes. It has been made almost anywhere in France, and, curiously enough, several of the larger and most noted French businesses are in the hands of Germans—Roederer, Mumm, Heidsieck, etc. There are also several English firms — Ackerman-Laurance, the shippers of Dry Royal Saumur, being one of the chief.

England heads the list of countries with the greatest consumption, followed by America, though whether this last is intended to represent the United States alone or the whole of the two divisions of the continent is not stated. Australia at one time was well to the fore, but it is stated that the recent financial troubles there have had an ill effect on the consumption of the effervescing beverage. The Russians have always had a partiality for champagne; but France, on the contrary, hardly wets her lips with it.

Champagne Cider is, or should be, the best mellow or sweet cider, bottled before it has fermented or worked much, and is not unfrequently made the basis of factitious *Champagne*. It is quite frequently made:—

(1) By charging common cider that is deficient in spirit and sparkle, with carbonic acid gas. *German Champagne* is of this character. (See *Cider*.)

(2) Put in a cask 18 gallons of cider, 3 pints of rectified spirit, and 5 pints of syrup; in three weeks' time fine it with 1 pint of skimmed milk and 1 gill of orange flower water—three drops of neroli will improve it—bottle in champagne bottles and wire down the corks.

(3) Flavour lemonade syrup with the essence of pear, and colour with brunt sugar.

Champignons.—A French name for *Mushrooms*.

Chantilly Soup. — F. *Purée de petits pois*.

Is made of green peas, onions, and meat stock, coloured and flavoured with spinach and parsley or mint. The vegetables are all simmered or boiled till soft, and put through a fine sieve. Sometimes pea-shells are used instead of peas.

Chapelure.—A French name for the raspings of bread used by cooks in garnishing certain dishes, roasts, etc. (See *Holder's "Victorian Raspings."*)

Charas or **Churrus.**—See *Bhang*.

Charcoal, Ivory Black, etc.—F. *Charbon de Bois*; W. *Golosg*.

Common charcoal is made by burning and charring wood or other vegetable substance, and consists of the residue left when such matter is subjected to a high temperature in vacuo, or out of contact with air. Tar is obtained at same time.

Animal Charcoal, a valuable pigment for painters, is produced in a similar way from bones, horns, ivory, blood, etc., and is synonymous with animal black, bone black, and ivory black, abaiser, etc.

The quality of *Ivory Black*, however, depends upon whether it is really produced from ivory or from the allied substances. It is well known that a great deal of what is sold as ivory black is merely the charcoal of hard woods reduced to powder.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating charcoal. Catalogues free.

Charqui. — (See also *Den-Deng* and *Tasajo*.)—A name for hard, sun-dried beef, as preserved in South America.

In preparing the dried meat for export in Chili, whence about 250 tons are shipped yearly, the bones and fat are removed from the flesh, which is cut into strips a quarter or three-eighths of an inch thick, and hung up in the full

rays of the sun, and in about eight hours t is dried as hard as a piece of glue. It is then packed in raw hides, which hrink upon it and keep it very tight. Meat dried in this way does not putrefy, but after a time mites are found in it.

In Buenos Ayres, where it is first partially salted and afterwards dried, the at is left, and the meat becomes rancid, but with the negro populations of Brazil and the West Indies (for whom it is hiefly intended) a little fat is an dvantage in their soups and stews. Mutton is dried in same way, and called Chalona. The exports of charqui, or ried beef, from Buenos Ayres amount o about 40,000 tons annually.

Chartreuse.—(See also *Liqueurs.*) highly-esteemed tonic cordial, btained by the distillation of several romatic plants—balm, hyssop, pepper- int, cloves, nutmeg, the seeds of *ngelica*, *Archangelica*, and especially ettles, growing in the Alps. Sugar and lcohol are added.

It derives its name from the celebrated onastery La Grande Chartreuse, near renoble, Isere, France, where it was riginally made by the Carthusian onks, and it is said they cleared up- ards of £8,000 a year out of it; but in 864 the Pope prohibited the monks om making it any longer for sale, and s the formula has never been made nown, the Chartreuse now sold is said be only an imitation of the original.

Chartreuse, however, still seems to be ie most celebrated of all liqueurs, though it only dates from a recent eriod. In 1830 it was quite a curiosity Dauphine, and even in Paris it was ardly known. At Fourvoirie, at the ntrance to the desert of the Grande- hartreuse, about five miles from the onastery, the monks distil three kinds liqueurs—the Elixir, the Yellow hartreuse, and the Green Chartreuse; ie last named is ranked as the best. he distillery is under the supervision of monk chosen for the purpose; it is true iat hands outside the monastery are ngaged in the work, but they know othing of the ingredients used or the ay in which they are mixed. It is said that this secret was discovered by an innocent-looking young man who got himself received into the order, and during the absence of the prior stole the recipe from his desk. The prior did not prosecute him, but allowed him to make use of his discovery on the condition he kept it secret. The *faux frere* (fictitious brother) is now established at Saint Laurent du Pont, where he fabricates chartreuse, but it is not equal to that of the monastery. So runs the story, although the monks say it is all romance. These worthies aver that the predominating savour of the true concoction is due to an occult mountain herb known only to themselves.

There are four qualities—White, the mildest sort, but too sweet for some people; Yellow or amber coloured, of medium strength, reputed to be the best, and has by far the largest sale; and two of light Green colour—one of the latter being very strong and sweet, while the other is pure, very clear, and fiery, but too alcoholic for most people. Each bottle of the green is encased in a turned wooden case or bellows.

Gross annual output about a million and a half of bottles.

The distillery pays to the State yearly the sum of 1,000,000 francs. (or £40,000) for duty on the spirit it uses. This simple fact will give some idea of the amount of liqueur it produces. All the profits go to the Order, no individual monk being permitted to touch a farthing. The money is understood to be spent in works of charity, but a large portion is reserved for the fund of the Order, which is the richest in the world.

Since the passing of the Merchandise Marks Act of 1887, this brand, "Chartreuse" or "La Grande Chartreuse," as manufactured by the late Lous Garnier, has been registered by the Rev. G. A. Grezier, who, as assignee, claims the sole proprietorship. The bottles are made with bulged necks, and marked with a "cross," surmounted by "seven stars." These marks and labels have never been known to be forged, but old bottles are often refilled in hotels and restaurants, etc., with fictitious concoctions.

Chateau d'Yquem.—A renowned white French wine, produced near Bordeaux, and considered the most luscious and delicately aromatic of the Sauternes, its resplendent colour resembling liquid gold. Its exquisite bouquet and rich delicious flavour is said to be due to the presence of mannite, which has the peculiar property of not becoming transformed into alcohol and carbonic acid during fermentation. The Chateau d'Yquem formerly belonged to the house of Sauvage d'Yquem, who transferred it by marriage to the Seigneurs de Lur-Saluces, and to which noble family it still belongs. The estate is situated at Sauterne in Gironde, and contains 148 hectares, ninety of which are devoted to the culture of the white grapes which produce the world-famed wine. The prices which some of the matured wines attained have been sometimes fabulous, and 24,000 francs per tonneau of four hogsheads have been paid for some 1847's, at which price (which is £240 per hogshead) the Great Duke Constantine, brother of the Emperor of Russia, bought four hogsheads during his sojourn at Bordeaux in 1859, and since then it is said that as much as £4 a bottle has been given by the Bordeaux trade for the same wine for Russia. The grapes which produce the wine consist of three varieties, called Sauvignon, Blanc Semillon, and Muscatel. They are gathered only when beginning to rot, or become covered with a kind of down which gives them an almost mouldy appearance. During this period the fruit under the influence of the sun ferments within its skin. Each individual berry is watched and carefully separated from the bunches with special scissors by an immense number of women who go daily round the vines during a period of three weeks or a month. From this mode of gathering results the creation of various qualities of wines, as the most perfect berries are naturally first gathered, when gradually the choice becomes reduced and the average of the gathering less perfect. Each gathering is classed in generally either three or four classes, termed as follows:—Extra creme tete, creme tete, centre, and queue, or final gathering, when all the grapes remaining on the stalk are picked. Sometimes the whole is blended together, and sometimes it is separated; it depends, of course, on the disproportion in the classifications, which sometimes are so great that there is no resemblance whatever between one and the other.

Chateau Wines.—There are so many of these that it has been considered best to describe each under its particular name; thus Chateau Latour will be found under *Latour*, Chateau Chamboureau under *Chamboureau*, Chateau Margaux under *Margaux*, etc.

Other Chateau Wines are:—Cussac, Lanessan, Chasse - Spleen, Cos d'Estournel, Leoville. Ripeau, Badette, Respide, Rieussee, Peyraguey are *white* wines.

Chawls.—A name for the cured and smoked cheeks of pigs (See *Bath Chaps*.)

Chayotes or **Chocoes.**—The fruit of a cucurbitaceous plant, *Sechium edule*, native of Mexico and Venezuela, but now cultivated in Madeira, Singapore, Ceylon, India, and other tropical countries. They are about four inches long, oblong, tuberculate, and yellowish. Usually to be seen in Covent Garden Market. They are eaten simply boiled, and somewhat resemble the vegetable marrow.

Cheddar Cheese or **"Loaves."**—A rich, strong, fine flavoured, and spongy kind of cheese, either pale or coloured, made around Pennard, near Cheddar, in Somersetshire (but not in the village of Cheddar itself), and has been made in that district for over 200 years. "Cheddar" is also equally well made in many other districts, particularly in Ayrshire, Wigtownshire, and in Galloway district of Kirkcudbright, Scotland, also in Canada and the United States; and, in fact, this type of cheese is the principal kind consumed in England. It seems to have derived its original celebrity from the rich and aromatic herbage peculiar to the Mend

ills and dales which partly surround the istrict. The cheese are made of round ick shape, and weigh from 70 up to 50 and 200lbs. each. Immense uantities of this class are also imported om Canada and the U.S.; but the eneral weight is about 70lbs. Canada pplies a large quantity of cheese of heddar shape, but these are usually met ith in skins or cloths, while the genuine heddars are not.

A choice Cheddar possesses a very ch mellow flavour, and when ripe conins about 28 per cent. of casein, 16 albumen, 24 of fat, 28 of water, and out 4 of ash.

The method of making Cheddar eese is the one most practised in Great ritain, Canada, and the United States. he milk is allowed to stand over night, e cream removed to allow the milk to heated, and then returned imediately before adding sufficient rennet curd it in 20 minutes. The whey ving been run off, the curd is drained, t, stamped, salted, and placed in the eese press for two and a half days.

The evening's milk is usually kept d mixed with the new milk in the orning. Cheddar somewhat resembles d nearly equals Parmesan, and it ings a high price.

In making it the whey is several times immed off, then well beaten, and ured again over the curd to *scald* it. ie eyes or vesicles usually contain a h oil. About two-thirds of it is made thout colour and one-third with. The w make reaches the markets in nuary to April; but the finest is made May, is soft and fat, neither hard nor mbly, has a nutty, pleasing flavour, ither sweet nor acid. It should be ch and mellow, with consistency of dy of close silky texture, pure and en colour—not a mottled or streaky, d should have a prepossessing appearce and finish. This appearance and ish is seen on the outer surface, and cludes symmetry of shape, smooth, ar skin, and not unshapely, or with surface dirty and cracked open like ked clay.

The warmer the room in which the cheese is kept the more rapid is both the ripening and the subsequent falling-off. Hence it is that cheese made late in the season keeps better and longer than that made early.

The best ripening temperature is about 65° F, and to check or stop the ripening 40° F is recommended.

Cheese.—Arm. *Caus;* Du. *Kaas;* F. *Fromage;* G. *Käse;* Ir. *Cais;* It. *Formaggio, Casi;* Nor. *Ost;* Port. *Queijo;* Rus. *Sur;* Sp. *Queso;* W. *Caws.* (See also *American, Dutch,* and *Canadian Cheese.*)

Cheese is the curd, casein, or solids of milk; coagulated by being warmed and mixed with rennet or acid; separated from the serum, whey, or watery part; wrapped in a cheese-cloth, and pressed in a strong vat, hoop, or mould, called a "chesset," till dry. The average yield is about 1lb. of cheese from each gallon of milk.

Ordinary cheese is composed of 30 to 50 per cent. of water, 20 to 35 per cent. of casein, and a *whole milk cheese* should contain about 20 per cent. of fat; if less than ten per cent. it should be classed as *skim* or *blue-milk cheese.* (In Cumberland this is dubbed "Canter" cheese.) England uses, it is said, more cheese than any other European country. The amount of cheese imported by the combined countries of Europe is about 480,000,000lbs., and of this the United Kingdom takes considerably more than half. France imports 63,000,000lbs., and Germany 40,000,000lbs. England makes a large quantity of cheese, but eats it nearly all, and only exports about 4,000,000lbs. The quantity produced in the United Kingdom is probably about 100,000 tons, or one-half the consumption, the importation reaching over 100,000 tons yearly, chiefly from North America and Holland. Germany exports over 40,000,000lbs., and France between 16,000,000 and 18,000,000lbs.; Switzerland sends away 86,000,000lbs., and Holland 112,000,000lbs. The value of cheese produced by a good cow is estimated in Canada at £7, in Parma at

£10, in Neufchatel at £14, and at Camembert, France, at £36 sterling. In England an average cow produces milk for 3 or 4 cwts. cheese yearly, or more than double the weight of the butter. There are many kinds of cheese, which differ from one another according to the richness and sweetness of the milk employed, and of the pastures in which the cattle feed, also according to the mode of preparation. A large quantity, probably one-fourth, of the cheese consumed in this country is that known as the "Cheddar" make. England is, indeed, particularly celebrated for the abundance and excellence of its cheese; Cheshire and Gloucestershire are two of its most famous counties. English, Scotch, and American cheeses are mostly made *hard*, so as to keep good a long time, but many of the Continental varieties are made soft and must be used quickly, or they soon decompose and smell objectionably.

Probably a great portion of this "*Canadian*" was really made in the United States. The freight and charges from America to England are only 1d. per 8 or 10lbs.

Imitations of the celebrated and higher-priced kinds of other countries and districts are often made in England, America, and elsewhere; but many of the processes, especially the Continental ones, are kept secret, and pastures do not all impart the same flavour, so that these latter are rarely imitated so successfully as are those of certain English counties. Common makes are often scraped, greased, and polished outside to represent superior quality. The blue mould so much esteemed, and also the red mould, are vegetable fungoid growths, and specially affect the finer and richer kinds. It has been found, however, that cheese like Camembert, Brie, Neufchatel, Stilton, Cheshire, etc., can be closely imitated in flavour, by the bringing together side by side during the ripening process the foreign cheese and the cheese in process of manufacture, so that the organisms of the old cheese are transferred to the new.

"*Hay Cheese*" is a term used in Lancashire and some other countries to define cheese produced from hay or stall-fed cattle.

"*Culls.*" — Faulty, ill-cured, or inferior cheeses which have been sorted out from the better keeping kinds, to be sold at about half-price and consumed quickly.

Truckle Cheese.—Means a small thick, solid cheese that can be rolled on its edge, as the "Cheddar Truckles."

The maggots often found in new cheese are the larvæ of the *piophila* fly.

The cheese-mite (a species of *acarus*) attacks for the most part old and dry cheeses.

Rotten cheese is very unwholesome, but ordinary cheese is not necessarily considered unsound owing to the presence of parasites, yet it may, of course, be so badly infested with multitudes of maggots or mites as to be liable to seizure by the authorities.

Cheese may be so damaged by sea water, for instance, as to warrant it being seized; or through being kept in an unsuitable place, or otherwise, the butter fat in it may have become rancid.

Cheese should be stored in a fresh, *clean*, cool, and damp place rather than too dry. The poorer the quality the better it will keep and *vice versâ*.

If well salted and freed of all whey most hard cheese will keep good for several years.

Cheese that has become too dry, and cheese cuttings or crumbs, may be utilised for stewing, or for preparing grated cheese, or for Welsh rare-bits.

People's tastes differ very much as to cheese, and some prefer it in a state of decay, and even "alive," and, indeed, it might be hard to show why *mou*

(which is vegetation) should not be eaten as well as salad, or maggots as well as eels; but decomposing bodies can scarcely be good for human food. Cheese improves by ripening to a certain point, but afterwards it deteriorates. Much of the American cheese is so largely mixed with animal fat as to undergo, instead of "slow ripening," rapid rotting. (See *Margarine Cheese.*)

In towns it is more economical for consumers to buy their cheese fresh cut in small quantities as required than to obtain large quantities and allow it to go out of condition. Pliny was the first of ancient writers to mention cheese, and, while praising that sent to Rome from Nimes, alludes to that made in the Valley of the Po as being sour. The amiable and witty A. Brillat-Savarin, admittedly the most enlightened of gastronomists, has said that a dinner without cheese is like a lovely woman with only one eye!

Soft Cheeses are generally made by adding the rennet to the milk at a low temperature; the acidity is not encouraged, and the cheese is subjected to very little pressure.

Australian Cheese, the finest quality is now produced at Bodalla, in the southern coast districts of New South Wales. It is firm, of a reddish colour, and possessing a flavour resembling that of English Gloucester.

The flavour of cheese depends very much on the pasturage of the cows. Old grass pasturage, which is not treated with artificial manure nor used by other animals, is best. Cheese should consist solely of the casein and fat of the milk, for if any serum or whey be left in, trouble will ensue from the fermentation of the sugar, causing the cheese to heave and become porous and strong in flavour.

As regards the colouring of cheese, annatto really adds no good property to it, and all practical dairymen select uncoloured for their own use. Coloured cheese is no richer in fat than uncoloured, but it is often ignorantly credited with being richer, and thus fetches a higher price than white. The added colouring merely gratifies the eye, while it often really injures the cheese as a food, the astringent properties of the annatto reducing the coagulative power of the rennet.

A cheese scoop trick, perhaps not known to everybody, is to probe deeply an inferior kind and replace the sample withdrawn by a similar piece of *good* quality and then in selling the bad cheese to show the good sample. Cheese, especially if not well masticated, is not very easy to digest, and *skim-milk cheese*, hard and tough, less so than the richer varieties; but it has many other advantages, being cheap, portable, easy to store, ready for immediate use, and palatable.

Protein in food is the material used to rebuild the muscular system, so the labouring man needs a large supply of this element to maintain his strength and energy. There seems little doubt, however, that the endless variety of fish, fowl, fruits, and other meats, frozen, tinned, or dried, is lessening the consumption of cheese.

A pound of cheese is said to contain as much solid flesh-forming food as a pound of lean meat.

It has been said that a rich cheese puts fat upon the stomach, but that a lean or blue-milk cheese puts muscle in the arm.

A good cheese has generally rounded edges and sides, but too much bulging betrays fermentation.

A poor cheese has sharp edges, and is often crumbly and dry.

When a piece of rich cheese is rubbed between the fingers it feels smooth and melts.

Subjoined is a list of the best known sorts, both English and foreign, each of which is more fully described under its own title:—

Alpine Cream	Brick-bat
American	Brie
Bachstein	Bringen
Ball (Edam)	Cabrillon
Banbury	Cacio Cavallo
Bath	Caerphilly
Bavarian	Cambridgeshire
Blue Veiny	Camembert
Bondons	Canadian

Imports of Imitation Cheese in 1897 from the United States and Holland, 11,874 cwts., value £19,114.
„ „ 1898 „ „ 10,165 „ £15,327.
„ „ 1899 „ „ 5,687 „ £10,049.

The Australasian import consists mainly of New Zealand cheese.

In handling cheese cleanliness is often sadly neglected. It is laid about the shop in a dirty, greasy state, that not only spoils the cheese, but repels the purchaser.

In cutting cheese, the counter, knives and all utensils should be kept thoroughly fresh and clean. The be

vegetable wrapping paper should also be used.

Ordinary cheese should be always kept in a cool place, and, if new, should be turned, to begin with, twice a week. Afterwards once a fortnight until cut. Sometimes, a little butter spread on the side of the cheese not used keeps the same from wasting and drying. In cutting factory cheese, the wire should always be used.

Importers:—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; W. A. McKnight (Canadian and States), 24 Mathew Street, Liverpool; R. Rutherford & Co., 112 Whitechapel, Liverpool; J. Wall & Co., Ltd., Liverpool and Manchester; Thos. Wilson & Co. (Cheshire cheese), 3 Hood Street, Liverpool.

Cheese Colouring. — (See also *Annatto*)—Digest one part of roll annatto and one part of potassium carbonate in 10 parts of water for 24 hours. Then filter, adding water if necessary.

Cheese Curd.—A mixture of cassein and butter, carefully freed from milk and water by gentle pressure, and the addition of a little salt.

Cheese Spice.—According to Mr. Allen, the public analyst of Sheffield, this consists of crystallised sulphate of zinc. It is used to prevent the heaving and cracking of cheese, but is highly dangerous to health.

Chequers.—A provincial name for *Service-berries.*

Cherimoyas.—(See also *Custard Apples.*)—The fruit of the *Anona Cherimolea*, imported occasionally from the West Indies, Peru, South America, &c. Very agreeable to the taste, but seldom to be met with in England.

Cheroots (pr. sher-roots). — A species of cigar open at both ends. The original are from Manila, in the Philippine Islands, and are very simply constructed. They are usually made of tobacco two or three years old, and are highly prized for their delicate herby flavour. The outside wrapper must be formed of new tobacco leaf, as it requires to be elastic. They are fit for use as soon as made and dried, and do not require any maturing.

Cheroots are also made in India, but these are somewhat inferior, the defects lying in the tobacco leaf and not in the manner in which it is rolled. Indian tobacco leaf is very light coloured, burns too rapidly, and gives the impression of smoking straw. It also soon becomes dry, especially in hot seasons, and requires some way of keeping it moist. Hence the material which Indian cigar-makers have to work with is not so good as it might be. Unfortunately most of the cheroots now sold in England are filled with very inferior tobacco.

Cherries —Du. *Kers;* F. *Cerises;* G. *Kirschen;* It. *Ciriege;* Port. *Cerejas;* Sp. *Cerezas;* W. *Ceirios.*

The fruit of the tree *Prunus cerasus*, and the favourite fruit of Queen Victoria, chiefly used at dessert and sometimes preserved, dried, and crystallised. It owes its name to the fact that it was first brought by Lucillus from Cerasus, a city in Pontus, hence also the adjective of colour, "cerise." This fruit is much used for flavouring liquors, the bark for medicine, and the wood for making toys and Tunbridge-ware, such as work-boxes, tea-caddies, desks, reels, etc.

There are also a score of species and over 150 varieties, but they may all be brought into two classes, viz.:—(1) *Geans*—black, white, or red—nearly heart-shaped, and with sweet juice as the Bigarreau, Tartarians, etc.; (2) Griottes—red or black—round or oblate, with acid juice as the Morello, etc.

The *White-heart* cherry, or Kentish Bigarreau, is an esteemed variety of *avium*, the body being almost white, with wax-like pink cheeks, and has the peculiar property of slipping from the stone.

The "*White Ox-heart*" cherries of California, now so very popular as a canned speciality form another example of this fruit. The Kentish and the larger Flemish cherry, both commonly known as Reds, are also very popular.

The keeping of cherries on the trees is the greatest obstacle to their culture,

birds and wasps being implacable enemies.

In England the principal cherry orchards are in Kent and Herts, where the *May Duke, Elton, Black Eagle,* and *Bigarreau* are old favourites.

Considerable quantities are also imported fresh from France and other parts of Europe, and the demand is increasing. In 1885 only 18,055 bushels were imported, but in 1893 346,148. Consumers seem to avoid the black cherry, because it is often infested with worms.

Winter Cherries, the shrublets of which often form such a familiar adornment at dinner tables, have, of course, no connection with edible cherries, being, notwithstanding the round cherry-like appearance, more nearly allied to the potato, the cayenne shrub, and the thorn apple.

Cherries are grown everywhere in France, but mostly in Lower Burgundy and the department of the Yonne. St. Bris and Auxerre are in the centre of a remarkable cherry district. Large quantities are also grown around Villiers, St. Frederick, Seine-et-Oise. The Bigarreaux are somewhat crisp, not very digestible, and should be eaten in moderation. The *Guignes* (White-heart cherries), very sweet and globular, and the bright red *Griottes* (Agriotes), very soft and sour, are dried for consumption in winter, and are stored like apples on shelves. The last two species in the South of France are largely used for making jam and for preserving in brandy. Indeed, the French make much more of this fruit than the English. Hence we import *Confitures de cerises* (preserved cherries), *Compotes de cerises* (cherry jam), *Sirop de cerises* and *Ratafia de cerises.*

Cherries in Kent are mostly gathered by women, but elsewhere boys and men are employed. The fruit should be ripe, evenly coloured, and free from damage. Usually packed in "half sieves," holding 24lbs. Early and choice Bigarreau and other kinds are placed in quarter sieves of 12lbs. The baskets are lined with clean paper, folded over the fruit, a little grass or similar material placed on the paper, and then secured with split hazel sticks in the form of a cross. All cherries must be perfectly dry when gathered. Choice kinds, cut off the trees with scissors, are sometimes packed in 10lb. boxes. Very fine cherries are also marketed in 2lb. boxes or baskets (unreturnable) or in 1lb. punnets. To pack cherries in bushel baskets is absurd.

Cherry Apples. — A popular name for *Siberian Crabs.*

Cherry Bounce or **Cherry Cordial.**—A cordial consisting of burnt brandy in which cherries have been steeped with sugar.

Cherry Brandy or **Cherry Syrup.**—Da. *Kirsebær Liqueur;* G. *Kirschen,* or *Kirschenbrantwein;* Port. *Aguardente de cerejas;* Sp. *Aguardiente de cerezas.*

A popular cordial or liqueur made from crushed Morello or other cherries and brandy—say a gallon of each, with 2lbs. of lump sugar steeped three days. Sometimes it is made from our native wild cherries or Black Geans, as the Scotch call them, and sometimes a quart of raspberry juice and half a pint of orange flower water are added. The fruit is usually gathered before it is ripe for this purpose.

The highest class of cherry brandy is made from Morella cherries—a layer of cherries and a layer of powdered sugar filled up with best Cognac. Grant's say they make theirs from Kentish Morellas.

A very superior kind of Cherry Brandy, labelled "*Kirsebær Liqueur,*" is manufactured by Mr. PETER F. HEERING, Copenhagen. Established 1818. Purveyor by Special Appointment to the Imperial Russian and Royal Danish Courts, and to H.R.H. the Prince of Wales. Sold by all the leading wine merchants. Original cases of 12 bottles or 24 half-bottles.

Cherry Peppers. — These are a species of capsicum, *Capsicum cerasiform,* the fruit of which is rather small, and shaped like a cherry or turnip radish.

"Cherry Ripe" Powders. — Intended for Headache, Toothache, Tic, and Neuralgia, are safe and efficacious.

For particulars, see advertisement, page 5. Sole proprietor, R. H. Poole, 120 Witton Street, Northwich.

Chervil. —A culinary plant (*Anthriscus cerifolium*), the herbage of which is used as an aromatic condiment. The parsnip chervil, also esculent, is *Chærophyllum bulbosum.* The sweet chervil (*Myrrhis odorata*) is an aromatic herb used in salad and culinary condiments.

Cheshire Cheese. — (See also *Cheese.*)—About 14,000 tons a year are made in Cheshire alone, but considerable quantities are also made in the adjoining counties of Staffordshire and Shropshire. It has long been famed all over Europe for its rich quality and piquant flavour, and is made in three classes—Early ripening, Medium, and Late ripening.

It is generally made of round shape, and varies in weight from 50 to 100lbs. Instead of being kept twelve months in the cheese-room the Early ripening is ready for use, and often brings the highest price, when only about a fortnight old. This early ripening is of new introduction, heat as well as pressure being used for the separation of the serum. The milk is set with rennet at 78° to 82° F., and the curd is first treated as in the manufacture of sweet curd cheese. It is afterwards drained on racks, to develop acid, and the curd is afterwards ground and mixed with salt. It is then packed loosely in perforated vats, and kept at 70° to 80° F. The whey escapes through the holes, and the cheese is afterwards put in press for a week, but turned and attended to daily.

When removed from the vat it is washed with warm water, greased to prevent cracking, and swathed in stout bandages. The cheese is finally put in a heated room, and is more slowly or quickly ripened according to treatment.

When a ripe Cheshire is cut into, mould will have greatly developed, and from the patches of mould inwards the cheese will appear to have lost some of its artificial colouring. This is due to the spreading of the mycelium of the fungus, which has found its way through the loose texture of the cheese, and has largely contributed to its flavour, character, and moisture. Such cheese is all right if eaten while in condition, but it will not keep long, and soon develops evil flavours.

The best qualities are seldom met with at the cheese fairs; the great bulk goes direct to the buyers in Manchester and other North of England towns.

The production amounts to something like 20,000 tons per annum, and Manchester seems to be the chief trade centre.

Highest and Lowest Prices for choice quality in Manchester each month.

Cheshire cheese is usually made solid, homogeneous, dry, and friable, rather than viscid. It is said to owe its excellence chiefly to the geological forma-

tion of the county, which is principally new red sandstone and boulder clay, and, as it has immense salt deposits, the herbage is well suited for cheese production.

Its component parts average:—Water, 30·4; nitrogen, 8·0; fat, 36·6; various, 25·0. It should be made from pure new milk, the morning milk being added to that of the previous evening, which latter is previously warmed to new-milk heat. A piece of dried rennet, size of a half-crown, put into a pint of water overnight and allowed to stand till next morning, does for 18 or 20 gallons of the milk, and it is probably to the unusually small quantity of rennet used for turning the milk that this cheese owes much of its mildness and delicacy of flavour.

The artificial colouring of this kind of cheese is much to be deprecated, and ought to be discarded. Consumers are not so ignorant as they were. Cheshire cheese-making has, indeed, undergone considerable change these last few years; the demand for it has fallen off to a great extent.

Consumers seem to prefer the higher qualities of early or acid ripened, open, and mealy cheese, and, as this will not keep long but must be consumed rapidly, farmers cannot hold it. The result is the farmers must all sell at once, regardless of price, and the old-fashioned, close, waxy makes that require months to ripen have been much neglected. Complaints are sometimes made that much American and Canadian cheese is sold as Cheshire, but no one used to handling cheese can possibly mistake one for the other, the nature and texture of each being quite apparent.

Cheshire cheese as sold at Chester and Nantwich scales 121lbs to the cwt.

Apply to Thomas Wilson & Co., 3 Hood Street, Liverpool.

Chestnuts—F. *Châtaignes, marrons;* G. *Kastanien;* It. *Castagne;* Pol. *Kasztang;* Port. *Castanhas;* Sp. *Castañas;* W. *Pipgnau.* (Also known as *Spanish Chestnuts, Sweet Chestnuts, Marrons, Water Nuts,* etc.)

The edible fruit of the chestnut tree (*Castanea vulgaris*) largely cultivated in Devonshire and various parts of Southern Europe, but especially in France, Spain, and Italy, where the crop averages about 2 bushels per tree.

In some countries they form an important part of the food of the poor, being eaten raw, boiled, or roasted, also ground into flour (*Chestnut Flour*) for bread, and called *Polenta.* Throughout the centre of France, from the Bay of Biscay to Switzerland, there are large plantations, almost forests, of chestnut trees. Some 5,000 tons are exported from St. Malo every year. The poor people through autumn and winter often make two meals a day from them. The chestnuts are first shelled and thrown into boiling water, and then blanched by rubbing off the inside skin. A wet cloth is then arranged in an earthen pot, and almost filled with the blanched nuts. After covering with a second wet cloth, they are put on the fire to steam, and finally eaten warm with salt and milk.

Hot steamed chestnuts are commonly carried round the streets in baskets or pails. They are also served, not only steamed, but boiled, roasted, pureed, and as dressings for poultry or meats. They are often used as a vegetable, and are very popular even on the tables of the well-to-do and wealthy.

Chestnuts blanched, dried, and ground into flour are made into bread or sweet heavy flat cakes, not unlike the oaten cakes of Scotland, by the mountain peasantry. Chestnuts, when stored, are very apt to heat and ferment. They require great care, and should be placed in cool, airy bins, so that the air may readily pass through and ventilate them. The Spanish or Sweet Chestnut, *C. Sativa,* is a stately tree, with spear-shaped leaves and tapering serratures at the edge. The leaves are yellowish, and form in long clusters; the fruit is enveloped in a husk, defended by numerous complicated prickles. They are not quite equal to the French in quality, although immense quantities are grown in Viscaya, Estremadura, and the

Asturias; but the best come from Italy. Spanish chestnuts may be eaten raw as gathered, or baked and flavoured with salt. If the nuts are gathered unripe, they are light and poor in quality; they should be allowed to ripen and fall. Any that remain in the husks should be taken out, and all thoroughly dried in the sun or in an airy room. They may then be stored in air-tight jars, or packed in alternate layers with dry sand, and kept free from damp and frost until wanted for use.

The annual production of chestnuts in Italy is about 400,000 tons, and the chief centre is Liguria, where the crop reaches about 2 cwts. per head of population.

Horse chestnuts are a wild and coarse species, and, although eaten by horses and some other animals, are very bitter and unsuitable for human food; nevertheless they are also made into flour.

Chestnuts contain the least oil, and are, therefore, the most farinaceous and digestible of all the nut tribe.

In some countries, and particularly in Canada, chestnuts are very popular at Hallowe'en.

Imported chestnuts have generally been kiln-dried and decorticated to prevent germination on board ship.

Indian Water Chestnuts are the fruit of a water plant (*Trapa bispinosa*), and are extensively cultivated in the North-West Provinces of India, China, and Italy.

They grow under water, large sheets of which are staked out with bamboos and regularly farmed. The nuts are of triangular form and covered with a rough brown integument, which adheres strongly to the kernel. The kernel is of white colour and of a fine cartilaginous texture. (See *Water* or *Trapa Nuts*.)

These Water Chestnuts afford food for the natives for about four months of the year. When roasted and reduced to a powder, the flour is considered more nutritive than rice, and is usually preferred to either tapioca or sago. *Chestnut Flour* and meal, first brought to notice in England as an article of food in 1879, is usually sold in original packets, and has a large sale among vegetarians, etc., in this country, and the demand for it is increasing.

Chevrets.—A French name for small cheeses made of goat's milk.

Chew Sticks.—These are the stems of a climbing West Indian shrub, *Gouania domingensis*. They are sometimes pulverised as an ingredient for tooth-powder. Pieces of the stem, with one end beaten into fibre, have also been used as tooth-brushes.

Chewing-gum.—(See also *Chicle Gum, Sapota*, etc.)—A popular American masticatory or compound prepared from *Chicale*, a sort of gum obtained from a Mexican tree, very similar to the india-rubber tree. Gum from young trees is best, lighter in colour, and better flavoured, than from old trees. Some sorts are made from a gum-resin got from spruce and other trees, but chiefly from the chicle extract obtained from the sapodilla tree (*Achras sapota*).

The manufacturing industry is, in fact, now being dominated by a trust, *The American Chicle Co.*, which is so-called from the fact that this peculiar vegetable gum has become the principal ingredient in most makes.

A quarter of a century ago there were only two kinds of chewing-gum in use in the United States, viz., the regularly prepared spruce gum and shoemakers' wax.

A little later a mixture of paraffin wax, with either resin, balsam of tolu, or similar ingredient, was put on the market, and was known as "*Coal-oil gum.*"

Preparations called "*Taffy tolu*" and "*Snapping wax*" were next introduced for similar use, but these were mere pioneers for the enormous trade which has sprung up in "Chicle chewing gum."

About 1884 a lot of this Mexican gum was sent to New York on board ship, partly as ballast and partly in the hope that it would be found suitable for use by bookbinders or possibly in the leather trade. After several trials it was thought to be quite useless for any known purpose, and, failing to find a purchaser, it

was decided to tow it out to sea and throw it overboard.

Just at that time one of the men standing on the wharf casually picked up a piece of the gum, examined it, and found it would "chew."

The idea at once occurred to him that it would form a suitable basis for making a new kind of chewing-gum, and, without difficulty, he succeeded in obtaining the whole lot for the trouble of shovelling it out of the ship. That man was a Mr. Adams, now a millionaire, several times over, and the head of the firm of Adams, Sons, & Co., 148 to 155 Sands Street, Brooklyn, New York, to whom we are indebted for above particulars.

How it is made.—Mr. Adams' first venture in making chewing gum was cooked in a tea kettle and worked up on the kitchen table. Now, the gum as taken from the bales is first chopped into small pieces and then boiled in water. Wood, pieces of bark, and all other impurities which are light, separate from the gum, float on the surface, and are skimmed off; whilst those which are heavy, such as dirt, stones, etc., fall to the bottom.

When the gum is perfectly clean it is ground up in a mill making about 3,500 revolutions a minute, and then subjected to a continuous heat of 140° F. in drying rooms.

When sufficiently dried it is sent to the cooks, who put it into large steam jacketed pans, and add to it pure white sugar, granulated pepsin, powdered kola, or other desired ingredients.

It is then kneaded into the consistency of bread dough. The "dough boys" then take it in hand, and add the flavouring ingredients, such as oil of peppermint, oil of winter-green, etc., etc., and, whilst still warm, thoroughly work it until it looks like gingerbread, finely powdered sugar being added from time to time during this kneading process to prevent its sticking. It is then allowed to cool, and afterwards passed through steel rollers until reduced to the proper thickness, when it is removed to the markers, steel-knived rollers, which partly cut through the long sheets of gum. Next it is removed to the seasoning room, and finally broken up into pieces of suitable size on the lines left by the markers. The finished gum then goes to the wrapping room, where the nimble fingers of young ladies wrap it in waxed paper, tin-foil, and pretty wrappers, and these to the packers, who pack it in jars or boxes, ready for sale to the numerous dealers.

All are sweetened and flavoured more or less with liquorice, tolu, peppermint, or other essences. An example:—Take of balsam tolu 4 ozs., white resin 16 ozs., sheep suet 1½ ozs., and melt together. Then of above mixture take 2 ozs., white sugar 10z., oatmeal 3 ozs. Soften and mix in a water bath. Roll the pieces in finely-powdered sugar or flour to form sticks, etc.

Paraffin, with a little olive oil and glycerine, are sometimes melted together for a chewing gum. The exact mixture of these varies with the season.

The chewing of gum is a very ancient custom in the East, where the gum used is mastic, slightly aromatic in character, and called "mastitia" or "gomma." It is found in plants largely cultivated on the Mediterranean borders, the finest varieties being obtained from Chios. The plant is a low shrub of the genus *Pistacia*. The term "mastic" is itself derived from the Greek for masticating or chewing. In Turkey and Armenia the women are in the habit of using this kind as a means of keeping the teeth clean and giving a sweet odour to the breath. It is supposed the habit of chewing it arose from the desire to dissipate the aroma of garlic from the breath. Its use certainly stimulates the salivary glands, but whether excessively and injuriously is uncertain.

The use of chewing-gum is one of the marked idiosyncrasies of the people of America, where, since 1868, it has had a very large sale. There are now in the United States at least five immense chewing-gum factories, a dozen others of moderate size, besides innumerable smaller concerns engaged in the industry. One company alone sells over five million dollars worth yearly.

and increasing quantities are exported to China, Japan, the Black Sea, Egypt, and to the gold and diamond fields of Australia and Africa.

Chewing gum was introduced into England about 1882, and is now sold by many confectioners, but, of course, it is intended for chewing and sucking only. It is used mostly by workmen and athletics, in lieu of tobacco, and the demand seems to be increasing everywhere. It is, however, an unsightly habit, and a wary professor in the States has hit upon the happy idea of informing the ladies that it spoils beauty by wrinkling the face.

Being very indigestible, it should never be swallowed.

Several deaths have occurred through young children swallowing it, and retailers in this country have frequently been fined for selling as "gum" compounds made up largely of paraffin "wax."

Chianti Wine.—A common low-priced Italian product.

Chiavenna Wine.—A Swiss product of the Grisons. It is a white and aromatic variety, made from the red grape.

Chica or **Chicha.** — A beer used from time immemorial in South America, and prepared chiefly from maize, but also from barley, rice, manioc, pineapples, or grapes. In Peru, where Chicha is the national drink, the corn is pulverised between two stones, the meal put to soak in water, and the mass is afterwards boiled. The juice is then fermented, and the result is a sour liquid, not unlike weak cider.

Chick or **Pigeon Peas** or **Gram.**—F. *Pois chiches;* Sp. *Garbanzos;* W. *Tdbys.*

The dark-brown or black fruit of an annual herb (*Cicer arietinum*), long cultivated in India, where they are called "Gram," and a few other warm countries. In Turkey they are known as *Camel Corn*, and fed also to horses and cattle.

This plant yields a short hairy pod containing one or two small netted seeds with two swellings on one side.

An acid liquor or medicine is got by collecting the dew from the leaves and pods in the early morning, which contain oxalic, acetic, and malic acids in solution. These are very irritating to the hands and injurious to the boots in walking through the fields.

The husked peas contain 21·7 per cent. of albuminoids and 59 per cent. of starch, whereas maize contains only 9·5 and 70·7. Hence, crushed gram mixed with an equal weight of ordinary food is excellent for horses. In India gram is the chief, and sometimes the sole, food for horses.

Chick peas are commonly sold in the shops throughout Spain, parched for food, and are much used in *olla podridas;* also are an important factor in French cookery. They are also roasted and extensively used in the East, where they form the common parched pulse.

When roasted they are said to sustain life longer than any other food in similar quantity, hence they are much used by travellers through the deserts. They are also very common in the bazaars at Calcutta. The juice is used by the ryots of India in their curries instead of vinegar.

Chicle Gum. — This is the coagulated sap of the Zapote (*Sapota Achras*) or "Ya" tree of the native Maya Indians in Mexico, and has lately been a favourite base with mesquite and other gums in "Chewing-gum" manufacture. It is gathered in the dense forests on the Campeachy coast in the rainy season, when it is "ripe," by the natives who, with wood knives and ropes, ascend the trees and cut in the bark canals down the larger branches, connecting them with a vertical cut down one side of the trunk; whilst branch canals are cut so as to lead all the milky white sap slowly down into a receptacle below. The sap is at once coagulated on the spot by boiling in caldrons until it "takes point," *i.e.*, reaches a certain consistency, when it is poured into moulds to harden and dry. Each block is stitched in jute or hemp bagging ready for shipment, *viâ* Vera Cruz. The

gatherers being paid by weight, much dirt, gravel, and even cobble stones are mixed in it and sometimes paraffin. The best is of dingy greyish colour, about the consistency of beeswax, and free from impurities. The export from Progresso, in Yucatan, for 1896, exceeded by nearly a million pounds that of 1895, and altogether the export from Mexico must be about 1,000 tons yearly. (See *Chewing Gum*.)

Chicory.—F. *Chicorée*; G. *Cichorie*; It. *Cicoria*; Sp. *Achicoria*; W. *Ysgali*; Y. *Meirch*. (See also *Succory*.)

Grocers' or Coffee Chicory is prepared from the white milky roots of a perennial plant, distinguished botanically as *Cichorium endivia* or *chorée endive*, belonging to the same family as the dandelion, but grows 1 to 5 feet high. It is a native of China, but grows wild in many parts of the Continent. It is cultivated principally in Belgium, Holland, France, and Germany, also in the Eastern counties of England.

CHICORY.

A Continental variety, known as Witloef (*C. intybus*) or small chicory, is especially cultivated in gardens for its leaves, and used as a winter vegetable or for salads; but both may be traced back to the *chorée sauvage*, and, according to Jussieu, are indigenous to the European Continent. The leaves of the common variety of chicory, called in France *Barbe de Capucin*, are very bitter, and are little used at the English table (see *Salad Plants*). There are about 200 chicory works in France, but most of the chicory used for mixing with coffee comes from Belgium and Holland, where the production is still increasing, and where it largely replaces coffee in the lower ranks of society.

Foreign Chicory	1899	1898	1897

„ Exports . .	590	485	1482

The plant is sown in the spring, grows 6 feet or more in height, blossoms in August or September, and can be easily recognised by its bright blue flowers, which measure about 1½ inches across.

The root is white, large, fleshy, and carrot-like, running deep into the ground. It contains a large quantity of sugar, some of which during the process of roasting becomes caramelised, and really imparts a bitterness very like coffee. When dug up the root is washed, cut into small pieces, and dried in a kiln until shrivelled up to about a quarter its original weight. It is afterwards roasted with a little oil or fat to prevent it burning, ground into powder, and as it yields a larger amount of extractive matter, and is much cheaper than coffee, it has long been used to mix with the latter. Its use in this way originated in Holland about a century ago, was first noticed in England about 1830, and prohibited in 1832; but in 1840 the law was again altered, and its use permitted if clearly labelled and sold as "a mixture of chicory and coffee." The addition of 1lb. of chicory to every 8lbs. of coffee is by some of the best judges even considered an improvement. Properly roasted, chicory is of a fine blackish-brown colour.

Chicory, however, is quite destitute of the exhilarating and restorative properties of coffee, and only gives bitterness and dark colour. The little oil, butter, or lard added in roasting, say 2lbs. to each hundredweight, also gives it the exact lustre of genuine coffee.

Analysis shows chicory to consist of water, 9·09; soluble salts, 4·20; soluble extractive substances, 41·29; soluble gummy resinous substances, 5·22; dextrine, 6·12; saccharine matter, 11·36; cellulose, 19·40; caramel, 2·10; carbon, 1·18; empyreumatic oils, 0·04.

Its consumption is said to conduce to the growth of hœmorrhoids. Mochara chicory is a preparation of roasted and pulverised figs.

The immoderate use of chicory in coffee is said to have injured the sale of this latter, even chicory itself has often been found adulterated with red earths, Venetian red, and flours of wheat, rye, beans, mustard husks, etc. If kept a long time it is apt to cake, and when badly made or badly stored it changes rapidly. It swells up by absorbing moisture from the air, thereby bursting the packet in which it is contained, and soon becomes covered with mould, consisting principally of Peicillium galucum and Aspergillus glaucus. In this state it is evidently unfit for food.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

For chicory, apply to Hedley, Gamble, & Crosfield, Circus Street, Liverpool; Morris & Jones, 13, 15, and 17 Sir Thomas Street, Liverpool.

Chili Saltpetre. — See *Nitrate of Soda.*

Chili Vinegar.—This is easily prepared by soaking capsicums, chillies, or cayenne pods in ordinary vinegar, or acetic acid and water, and then filtering.

Chilled Meats.—See *Beef chilled*, *Pork chilled*, *Frozen Meats*, etc.

Chillies.—(See also *Capsicums* and *Cayenne Pods.*)—The Mexican and American name for the small species of the Capsicum, such as *Capsicum fastigiatum* Bl. (*C. minimum* Roxb.), which bears two pods in the axil of the leaves, whilst the two other species have only one. Both the thin, smooth, shining, and brittle pericarp and the inner seeds, flat shaped and of yellow colour, are intensely pungent.

Large quantities are grown in Africa, especially in eastern Zanzibar, but the plants receive very little attention from the native growers or Wahadimu. The pods are of a dull brown colour, but very pungent. Not half of the crop is ever gathered, and they are very carelessly dried. In fact, they are often purposely damped on the way to the coast for shipment, so as to increase their weight, and these soon ferment and spoil unless quickly re-dried.

The production in Zanzibar has increased from 16,336 frasilas (a frasila equals 35lbs.) in 1895 to 16,511 frasilas in 1896. There is no doubt that a more valuable product could be obtained if proper care and attention were bestowed upon the cultivation of this commodity, which is attended by considerable discomfort to the native workman, contact with the plant causing irritation to the eyes and skin.

All these small pods are better known as chillies than by the Pharmacopœia name of "capsicums," which latter is more commonly applied to the much larger fruit of "*capsicum annuum.*" During the last three or four years a very clean, bright red variety of chillies, *C. minimum* or *C. fas*, has been coming from Japan. It is less pungent than the dull dark red and inferior African growths, but of finer aroma and more attractive in colour, and seems to correspond with the orange red form of the variety conoides of *C. annuum.* The word "chillies" must, however, be a misnomer for a vegetable with so high a temperature (in the mouth!).

Bird's Eye Chillies or *Bird Peppers* are a still smaller variety and of superior quality.

Apply to Allen Jeeves & Sons, Seddington, Sandy, Beds.

Chimney Cleaners. — Many of these are formed of a mixture of two parts of sulphur and one part of common salt, but a superior kind, known as "*Anti-soot*," is made by Fitch & Sons, Tamworth.

China Cement.—(See also *Cements*, *Liquid Glue*, etc.)—The following is a useful formula:—Take of gum ammoniacum, 3 drachms; Brazilian isinglass, 3 ounces; distilled water, 6 ounces; methylated spirit, 12 ounces. Add 4 ounces of spirit to the water, in which dissolve the isinglass by the aid of gentle heat; dissolve the gum in the remainder of the spirit and add to the previous solution.

China Clay.—A white clay which produces a very fine powder.

China Nuts.—See *Lychees*.

China Oranges.—See *Oranges*.

Chinese Artichokes.—*Crosnes* or *Stachys Tubers*. These are tuberous underground stems, now grown in England, Ireland, France, and Switzerland from the Japanese plant *Stachys tuberifera*, a member of the dead-nettle or labiate order, to which thyme, mint, sage, and other pot-herbs belong.

They have a swollen bead-like appearance, owing to the accumulation of food matter in the internodes. Though in 100 parts by weight, 78·3 parts are water, 2 parts are nitrogenous (*i.e.*, eight times as much as in the potato tuber), and 16 parts are a readily-digested carbohydrate known as galactan, a body which is much more digestible than starch, being allied to dextrin, and so much more easily converted by the digestive juices into soluble dextrose or sugar. As a vegetable for the table it should be boiled from 15 to 20 minutes in salt and water, and eaten with a simple white sauce, à la poulette, for example. The flavour is like that of boiled chestnuts. They are recommended as a sort of peptonised substitute for potatoes, especially for invalids or for people with delicate stomachs.

Chinese Bird-Nests.—See *Edible Bird-nests*.

Chinese Ginger. — See *Preserved Ginger*.

Chinese Spirits. — The Chinese word *Samshu* means distilled spirits, and covers the three qualities, known as *Leu Pun Chau* (half materials liquor), *Sheung Ching Chau* (or twice distilled liquor), and *Sam Ching Chau* (thrice distilled liquor), all of which are obtained from rice. They are all colourless.

The first, *Leu Pun Chau*, is made from equal weights of rice and water, fermented with a balm or odourless substance, composed of rice, bean flour, red earth, and cassia leaves. After standing about a month, this fermented liquor is put into a boiler and distilled. Retails at 5 cents. a catty.

Sheung Chin Chau is a little stronger than the above. It is made by placing in the still a quantity of Leu Pun Chau along with the usual fermented liquor. Retails at 7 cents. a catty.

Sam Ching Chau is the strongest; Samshu, the mixture from which it is distilled, consisting of a still larger proportion of Leu Pun Chau and less of the fermented liquor. Retails at 10 cents a catty.

In use, these drinks are never diluted. Leu Pun Chau is the most popular beverage, and is from 50 to 60 u.p., the others being considered too strong in alcohol for habitual use.

When these latter are used they are taken in very small sips only, and mostly on festival days.

Other Chinese beverages are prepared by mixing Samshu with certain substances, such as—

Ching Mui Chau, composed of Leu Pun Chau, sour plums, and sugar. Retails at 8 cents. a catty.

Mau Kan Chau, from Triticum repens, Leu Pun Chau, and sugar. Retails at 8 cents. a catty.

Chang Chau, from oranges, Leu Pun Chau, and sugar. Retails at 8 cents. a catty.

Mui Kwai Chau, from roses, Leu Pun Chau, and sugar. Retails at 40 cents a catty.

Ka Pi Chau, from Ka Pi (a bark used for rheumatism), Leu Pun Chau, and sugar. Retails at 30 cents. a catty.

Ning Mun Chau, from limes, Leu Pun Chau, and sugar. Retails at 8 cents. a catty.

Muk Kwa Chau, from papaws, Leu Pun Chau, and sugar. Retails at 8 cents. a catty.

Fa Chau is a liquor about 40° u.p., is obtained from an equal quantity molasses and Tso Sui (the mixture for making Leu Pun Chau); and this is used for making several of the wines in which Leu Pun Chau is ordinarily used. Retails at 7 cents. a catty.

Shüt Li Chau is made from Fa Chau and Tientsin pears. Retails at 8 cents. a catty.

No Mei Chau is a liquid of varied composition. Fa Chau is used for it, together with No Mei or full-grown rice, or No Mei Chau is frequently sweetened Leu Pun Chau, in the preparation of which No Mei or full-grown rice has been used. Retails at 7 cents. a catty.

Shan Kut Chau is a wine prepared from Shan Kut—a very small, hard, bitter orange—and Fa Chau. Retails at 8 cents. a catty.

All distillers in China also make sauces, by converting Leu Pun Chau or Fa Chau into vinegar, and adding the appropriate ingredients.

Chinese Starch.—So called because the use of starch in Europe was originally introduced from China, where, for ages, it has been made and is still made from sago. This is the article the celestials use as paste for fixing the outside paper on tea chests, boxes, etc., and it forms one of the most adhesive substances known. Before the times of Colman, Berger, Orlando Jones, etc., and the London laundry starches, all starch was made from sago, but the demand for this kind is now small, and the "*Glenfield*" is almost the only survivor. Only a few manufacturers produce it, although it is said to be the best kind for mounting photographs, etc., and will keep good a long time.

Chinese Sugar.—See *Sorghum*.

Chinese Teas.—(See also *Teas*, *Packet Teas*, and *Blended Teas*.)—The tea-plant, *Camellia thea*, or *Thea sinensis*, classed by botanists in the natural order Camelliaceæ, or more correctly Ternstroemiaceæ, has been cultivated in China some 2,000 years, as a sort of dwarfed shrub much smaller than the Indian and Ceylon growths, but is a much hardier shrub in China than in the others named. In China the plant is grown one to five feet high, with a bushy stem and numerous very leafy branches, resembling a myrtle in appearance. The leaves, two or four inches long, when fully expanded, are alternate, elliptical, obtusely serrated, veined, and grown on short thick channelled foot-stalks. The calyx is small, smooth, and divided into five obtuse sepals; the flowers are white, axillary, and slightly fragrant, often two or three together on separate pedicles, producing three-celled and three-seeded capsules.

Tea is cultivated more or less all over China, except on the extreme North, and its history or origin is buried in oblivion. No one seems to know at what period the infusion was first used as a beverage. A list of all the names and meanings for the different kinds cannot be given here, but the principal sorts are more fully described under their respective names. Whether green, black, red, tile, or brick teas, they are all produced by the same kind of shrub, merely showing a slight tendency to variation in different districts as regards length and width of leaf. The plant is propagated from seeds sown in rows about four feet apart, and in the course of two or three years bears a small crop of suitable leaf; at seven years old they yield only about 4 ozs. per tree, the finest teas growing between the 27th and 31st parallels of latitude. The leaves are picked at three or four periods of the year, commencing from the latter part of April. The bushes are also usually clipped to make some of the "brick" teas, and to encourage the growth of young shoots in the following spring. When picked, which has all to be done by hand, the

raw leaves are partly dried in the sun by spreading them on mats, and the shrivelled product pressed and rolled by men who stand in tubs, kneading the leaves into a ball with their naked feet. This operation gives a twist to the leaf, and removes superfluous watery juices. The tea is seldom dried by fire by the smaller tea-growers, unless the weather be wet and the tea likely to mould from the want of sun-heat. It is stored in bags long enough to collect a quantity, and is then conveyed to the larger tea-houses, "fired" by placing it in thinnish layers on pieces of wicker-work shaped like dice-boxes with both ends open, and put over a charcoal fire. The heat is never allowed to exceed 212° F., and the tea is afterwards sifted, winnowed, mixed, and picked over, and then fired again so as to get rid of any moisture acquired during the curing. When packed and soldered in chests it is not expected to undergo any further change; but often the charcoal fuel—especially if used damp—imparts a tarry or smoky flavour. It must be admitted that Chinese teas will keep longer than any other, and that they even improve and thicken by keeping.

Names of a few China Teas:—

Black Leaf ("Monings") from Hankow and Shanghai:—Ningchows, Oopacks, Oonams, Oonfaas, Kintucks, Ditto Congou, Moning Congou, Keemuns, Hohows, Kew Kiangs, Seangtams, Shantams, Tongsams, and Yclangs. Also Lapseng, Pouchong, Formosa Oolong, and Ning Yong ditto.

Red Leaf ("Kaisows") from Foochow:—Soo Moos, Suey Kuts, Ching Woos, Panyongs, Padraes, Saayunes, Souchongs, Young Hows, and Paklings, or Pekoe Congous.

Fancy Teas Glazy Ouchains, Scented Orange Pekoe, and Scented Caper from Canton. Some of the last-named are olive in colour, and others are black glazed. Ouchains are the small sifted from Scented Capers.

New-make Congou (in boxes) from Canton and Macao:—Tayshans, Fourth crops, Flavoury (or Honeysuckle) arrive December, January, and February.

Green Teas:—Moyune, Gunpowder, Ping-Sueys, Imperial, Hyson, Feong Mee, Young Hyson, Sow Mee, Tonkay or Twankay, and "Country" teas.

The youngest leaves make the best teas, and starting from the shoot, and numbering the leaves as they come from one to seven, the following varieties are obtained: (1) Flowery Pekoe; (2) Orange Pekoe (gathered in April); (3) Pekoe (in May); (4) First Souchong (in June); (5) Second Souchong (in July); (6) Congou (in August); (7) Bohea (in September).

1, 2, and 3 make *mixed Pekoes*, and 1, 2, 3, 4, and 5 make *Pekoes Souchong*.

It will be noticed that the above names really indicate only a gradation of qualities from the young bud to the full-grown leaf, each succeeding gathering being less fragrant and valuable, and the final one usually consisting of large old and withered leaves of little value.

At the end of the season the clippings of the bushes, stalks, and everything in the shape of tea are all worked up to meet the speculative and indiscreet foreign trader. Chinese teas have suffered much in the estimation of the British public owing to these low qualities, adulteration with young willow and other dried leaves, sand, etc., also from the fact that they are always worked up by the hands and feet; and those who have seen much of the hands and feet of the Chinaman prefer articles which he has not touched. On the other hand, Chinese teas contain much less tannin per pound than Indian and Ceylon growths. Sir Andrew Clark says: "If you want to have tea which will not injure and which will refresh, get black China tea."

Every nerve used to be strained to hasten the new crops of Chinese teas into the British market, and the fastest ships employed to bring the first cargoes. As the trade grew in importance, the advantages of rapid transit for the tea of new season's production began to be appreciated, and the slow and stately progress of the old East Indiaman grew out of date. A type of vessel specially designed for the rapid carrying of tea

from China to England, *viâ* the Cape of Good Hope, was introduced, known as the China clipper, and the competition was always keen as to which ship should make the most rapid passage. This culminated in the year 1866, when nine ships sailed almost simultaneously from Foochow, three of them crossing the bar in company. Those three were all built by the same builders in Greenock, and came in ahead of all the others, making the long voyage of fully 16,000 miles in 99 days. They each docked in a separate dock in London upon the same day, and all within two hours of each other. The two leading ships had not seen each other for 70 days, and met off the Lizard, from which point they ran a neck and neck race before a strong westerly wind, with every rag of canvas set.

The opening of the Suez Canal, in 1869, soon changed the course of all trade with the East, and in a few years the sending of tea per sailing ship round the Cape of Good Hope was a thing of the past. Romance was no more, although there was extreme competition in building steamers with great power and speed to land their cargoes rapidly by the new route. This culminated in 1882, when the ss. Stirling Castle made the phenomenal run, for those times, of 28 days from Woosung to London.

"New seasons" now arrive in London about the end of June. This new tea has certainly the most flavour, and the value is higher, but it is said the Chinese themselves prefer tea when it is a year old. In 1865, out of every 100lbs. of tea consumed in this country, 97lbs. were Chinese and only 3lbs. Indian, but in 1894 China contributed only about 50 per cent. and the consumer bought that about 50 per cent. cheaper.

A large amount of earthy refuse, stalk, and broken leaf has lately been coming from China in consequence of a tax being now put on the refuse tea in China, same as upon good tea. There used to be no tax on the refuse, and it was then all used in China by the poor, but it is now taxed, and consequently made the most of by exportation. (See *Tea Dust.*)

The kinds of Chinese tea which seem to have diminished most in export are the better Congous, Pekoes, Souchongs, Ponchongs, Capers, and Oolongs; others appear to keep their position notwithstanding the Indian growths.

The best Chinese teas are generally bought up in advance by Russian merchants and command big prices, there being in Russia, Japan, and China epicures more dainty as to their tea than any of our own magnates are about their wines, "Chops" running $100 to $200 per picul (133⅓lbs.), and extra fine pickings $10 to $50 per lb., being common. The Governor of Formosa, for instance, pays $10 to $20 per lb. for his tea, and it is certainly of excellent quality.

The Chinese never dye the tea they use themselves, but only that for export. They rarely consume other than the black kinds, and tea is the popular beverage, not only in China, but throughout Japan as well. It is sold in all public-houses (or "tea-houses") both in towns and along the roads.

The tea they use is prepared by a single "firing," after drying in the sun, and is a very different article from that prepared for the English market, which is sometimes fired several times. That for Russia which undergoes no special preparation for the short overland voyage which it has to make, is more like the Chinese native tea in flavour, and when prepared is altogether superior to that made in the teapots of English households, after the long voyage through the tropics, exposure in shops, etc.

Scented Teas.—Chinese teas, such as Capers, Orange Pekoes, Oolongs, etc., owe their freshness of flavour or perfume to leaves and flowers of various plants, the chief being a kind of jessamine, known in China as *Qui Fah.* The *Olea fragrans*, a fragrant kind of olive, native of China, the *Iris*, and the blossoms, roots, and oils of other plants are also used for the same purpose.

The flowers of the *Aglaia odorata*, the *Jasmium Sambac*, the Chloranthus, and the Gardenia are also often used to

scent teas. Sometimes the scenting is effected by mixing odoriferous flowers with the tea while fermenting and afterwards separating them.

The regions in China which export the most tea are the South-eastern—Kwang-tung, Fuh-keen, Keang-se, Che-Keang, Keang-su, and Gan-hwuy—black tea being produced in the more southerly parts of above districts, and the green teas in the country lying to the north.

Foochow, Amoy, and Canton are the oldest ports of shipment, but Wenchow has during the last three years assumed a remarkable prominence (see *Wenchow Teas*); while the trade of Amoy has been destroyed simply through the short-sighted greed of the officials, who have overwhelmed the growers with a series of illegitimate exactions.

In all tea-growing districts throughout China, the seeds of the tea plant not required for raising new bushes are collected and treated for their oil, which is there employed for both food and lighting.

It is a rather melancholy circumstance to see such a great inter-national commerce as that so long existing between China and England crippled and well-nigh obliterated, but it must be mainly attributed to the obstinate conservatism which has so long characterised the Chinese Empire.

Chinese White Wax. — (Also known as *Insect Wax* or *Pela Wax*, *Vegetable Spermaceti*, etc.)—A clear white wax, the joint product of an insect and one or more trees.

In Keenchang, on the Thibetan frontier of China, flourishes an evergreen tree known as *Ligustrum lucidum*, and in the spring myriads of small brown flies, called by entomologists *Ericerus pela*, swarm on the twigs of these trees.

The branches soon become covered with a white soapy incrustation—supposed to be an exudation of the insects in a state of disease, which increases until autumn, when the sprigs are cut off and immersed in boiling water. The water is kept boiling some time to destroy the insects, or larvae, and the viscid substance which rises to the surface is skimmed off, melted, and then allowed to cool in deep pans. It thus forms a beautiful white, translucid, brilliant, inodorous, insipid body. It is not greasy to the touch, and is harder than bees' wax. It cracks between the teeth, crumbling to a non-adherent, dry powder.

It has been found that by removing a little of the larvae in the spring from Keenchang to other trees in the rice district of Chia-ting, the flies being enormously prolific, increase amazingly, and the waxy deposit is considerably augmented, every pound of larvae producing 4 or 5lbs. of wax, which is worth a dollar per kilogramme at Shanghai. The process is repeated every year, and the crop of this wax, some 200 tons, yields about £650,000 annually.

Exported from Shanghai and Hankow in large round cakes.

It is often adulterated with 15 to 20 per cent. of water, which causes it to lose its lustre, and to become dull and more or less opaque.

It melts at 84° C. or 184° F., and is used in candle-making, sizing of paper and cotton goods, glaze for silk and polish for furniture, stones, etc. When genuine, this beautiful wax resembles bees' wax in its chemical composition more nearly than the vegetable waxes, and although, on account of cheaper substitutes, very little of it now comes to England, it is much used in Eastern countries, both in the making of wax candles and in medicine. It is said to have ten times the illuminating power of other waxes.

Chinois. — A dwarf species of oranges, which are grown to some extent about Nice, in France, but mainly in Spain, Algeria, Malta, Italy, and Corsica. They are cut up and preserved in several ways, sometimes in brandy and syrup, for sale in short-necked bottles, sometimes as jam and sometimes crystallised. (See *Crystallised Fruits.*) They are usually designated as *Chinois verts* or *Chinois blonds*, according to the colour given them in preparation.

Chittas. —See *Melons.*

Chives or **Cives.**—F. *Civette;* W. *Cenin syfi.*

The smallest variety of the onion or leek tribe of vegetables, with small flat bulbs, which grow in clusters. The botanical name of the chive is *Allium schænoprasum.* The leaves are often used for flavouring soups, stews, hashes, etc., and the young plant is also used instead of spring onions in salads.

Chloride of Lime.—(Also known as *Chlorinated Lime, Bleaching Powder,* and often improperly called *Chloride of Calcium,* which is a very different thing.)—A dry white powdery substance with a slight acid smell, prepared by the action of chlorine on dry slaked lime. It is composed of chlorine, 36·23; lime, 36·77. When exposed to the air it takes up carbonic acid and gives off *Chlorine,* which destroys bad smells. It decomposes about twice as rapidly in the open air as in a room, and solutions of it alter about six times sooner in light than in darkness. It is used for purifying drains, closets, sewers, etc., but chiefly for bleaching cotton, linen, clothes, paper, etc. Thousands of tons are made at Newcastle-on-Tyne, but St. Helens and Widnes in Lancashire are the main centres of production. Originally a by-product in the manufacture of washing soda, it has become one of the chief chemical industries, and washing soda itself is now merely a by-product of bleaching powder.

Chloride of Sodium.—A technical name for common salt.

Chlorinated Soap.—A medicinal soap made of Castile soap and chloride of lime mixed together with rectified spirit. One of the most powerful agents known for removing stains from the skin and for preventing contagion by contact. Largely used in hospitals, etc.

Chlorodyne.—A compound of chloroform, morphine, and hydrocyanic acid.

One popular anodyne of large sale is a dark brown, slightly turbid and viscid liquor, smelling strongly of chloroform, and containing about 15 per cent. of chloroform, 2 grains of morphine to the fluid ounce, a minute quantity of prussic acid, a little oil of peppermint, treacle, and hot spice, or Indian hemp.

It is said the sale of chlorodyne, chloral, chloroform, laudanum, etc., to ladies is becoming as common as that of alcohol to men.

Chlorophyll.—The technical name for the bright green colouring pigment, as noticeable in most leaves and plants. It can be extracted and prepared as a colouring substance for tinting oils, soups, grease, etc. Some commercial kinds are adulterated with aniline, malachite, and chrome-green, while others are prepared from poisonous substances. The best are harmless and do not change colour readily. They are sold soluble and either in oil, spirits, or water. Prices, 4/11 to 6/11 per lb.

Chocolate.—Da. and Du. *Chocolade;* F. *Chocolat;* G. *Chocolade;* It. *Ciocolata;* Port. and Sp. *Chocolate;* Rus. *Schokolad;* Sw. *Choklad.*

All these names have been derived from the Aztec word "Chocolatl," a beverage made in Mexico ages before that country was conquered by the Spaniards.

When Humboldt discovered the use of the cocoa plant he little dreamed of the immense consumption that was to follow the concoction of his first cup. It is to-day fairly in the way of becoming one of the principal foods throughout the world, and tends eventually to supplant both tea and coffee as a beverage. As a flavouring it already ranks second to vanilla, and in England is decidedly before it, for it is now used in all branches of cookery, pastry, creams, and so forth.

It is a significant fact that thirty years ago the consumption of chocolate was limited to a few of the larger towns in this country, and in the rural districts was comparatively unknown.

The taste for it seems to be an *acquired* one, and people have really to be educated to the love for it. Like tobacco and beer, it is at first distasteful and even nauseating, but when once the use of it has begun it is seldom afterwards absent from the household, and probably tires the taste less than any

other confection. Chocolate is also one of the most healthy foods known at the present day, and as prepared by two or three of our leading English manufacturers (Fry or Cadbury for example) may be used to any extent without harmful effects, but rather the reverse. Modern chocolate, like cocoa, is prepared from the roasted seeds of *Cacao Theobroma*, or Cocoa Nibs, as they are generally called, and mixed with sugar, sago, arrowroot, ground arachis nut, potato flour, maize-flour, or other similar farina.

It is often also coloured and perfumed with other substances, such as vanilla, cinnamon, cloves, musk, ambergris.

French Chocolates (excepting those made by the Compagnie Francaise) contain but little flavouring, and that generally vanilla.

They are manufactured with the best machinery and long enjoyed a reputation over most other makes, but great attention has been paid to the manufacture of chocolate goods in England during the last few years, and many of them, especially those of the firms named, are now undoubtedly superior to any made abroad.

We believe Fry's business was first established in 1728. A hundred years ago their first little *steam factory* was puffing away making the then famous "*Churchman's Chocolate.*" Now they are probably the oldest and largest manufacturers of chocolates in this country, if not in the world, and certainly no other firm produces such a constant stream of novelties.

Chocolat de Santé (health chocolate) is a French term for chocolate free from vanilla or other added flavour.

Menier's Chocolate is reputed to be all made from cocoa grown in the district of Rivas, Nicaragua.

In Belgium it is illegal to label mixtures as "*Chocolate,*" or even to sell as "pure" cocoa from which any of the fat or butter has been removed.

Cheap sorts, unfortunately, heavily and basely adulterated with unwholesome ingredients, are still put on the market by unscrupulous makers. Chocolates are, of course, always understood to be compounded confections, but there is no excuse for lime, ground lentils, maize, and bean flour, foreign wax and oils, various gums, cinnabar, red earth, and even *red-lead*, and pichurin or sass-afras beans. There is really no generally accepted standard definition of what chocolate should consist of, or to what limited. Coker-nut stearine, to the extent of 30 per cent., has been found in some of the cheap makes.

The Customs revenue from imported chocolates only amounts to about £1,600 a year, the duty being 2d. per lb. on the percentage of chocolate excluding other ingredients. When alcohol is used an extra spirit duty of ½d. per lb. is also charged.

In October, 1893, there were sold by auction in London about twenty tons of so-called *chocolate creams*, said to be made from locust nuts and chicory, with a small quantity of prepared cocoa-nut oil! A dealer caught re-selling the stuff at 1½d. per lb. was fined £25 and costs.

Shopkeepers often lose heavily by these cheap rubbishy fabrications, which when freshly made may appear of fair quality, but soon become hard, nasty, and unsaleable.

Good chocolate should dissolve readily in the mouth, without grittiness or rancid flavour. Perfumed chocolates may always be suspected as being intended to cover or disguise inferior cocoa or added substances.

The superior and delicate flavour of fine cocoa should be learnt by all retailers who study excellence in their goods.

For *Gaboon Chocolate*, see "*Dika-bread.*"

Spanish chocolates are, in the Pyrenees, commonly made by day labourers hired for the purpose by the village housewives, who supply the cocoa, sugar, and other ingredients. The Spanish are large consumers of chocolates, and like them highly flavoured with vanilla, cloves, cinnamon, musk, or ambergris. Each village has its two or three chocolate workers.

Chocolates are consumed either in the slab or tablet form; scraped and made into beverages; or, in combination with farina and other ingredients, made into sweetmeats of endless fanciful forms.

In preparing it as a beverage the solid chocolate is usually scraped very fine, worked into a stiff paste with milk, and carefully boiled. The pot is then filled up with more boiling milk, and well stirred or twirled into a foam or froth by a notched wooden instrument. It is then ready for pouring into the cup and sweetening as desired.

"*Confectioners' Chocolate*" should be made pure and unsweetened, and melt very readily with dry heat.

Low priced makes are, of course, to be had, but these are generally heavily mixed with farina, sugar, etc., and produced from the inferior grades of cocoa.

Leading chocolate manufacturers:—Cadbury Bros., Bournville, Birmingham; Compagnie Francaise, London Works, Bermondsey New Road, London, S.E.; James Epps & Co., Ltd., Holland Street, London, S.E.; J. S. Fry & Sons (makers of all kinds), Bristol.

Chocolate Creams.—These popular sweetmeats consist of a white creamy interior, coated thickly or thinly with chocolate paste.

In making them, the inside portion is made first from the same cream as is used in fondant making, viz., beaten sugar (see "*Fondants*"). The "cream" is run into starch moulds, and when set, the centres are sifted out. These small centres are now generally covered with chocolate in the following way. Each operator has a small wire cup with which a centre is picked out of a pan of soft chocolate. This is drained and placed on a board, securing a flat bottom, and a dexterous turn of the wire before it leaves the sweet, secures the little curl on the top which is the certificate of good work.

In some of the best factories the creamy substance is made of cacao butter, farina, and sugar; but the cheaper qualities are often made of Danish stearine, wax, etc.; and are apt to turn quite hard when kept a short time; whilst the "chocolate" covering is a mere skin made up from various substitutes coloured and flavoured in imitation of chocolate. These latter should never be stocked by retailers who respect their trade.

Chow-chow. — A Chinese, or Pigeon-English, word for mixed or miscellaneous. Hence the name given to a preserve made in Southern China of orange peel, ginger, bamboo, pumelo-rind, syrup, etc.

But the true *Chocho, Choco, Chavote*, or Chow-Chow is the firm fleshy fruit of the plant *Sechium edule*, and may be obtained fresh in our markets from time to time, especially about Christmas. (See *Chavote.*)

"*Chow-Chow Pickles*" are a kind of mixed pickles made with mustard and spices in the East Indies and imitated in England. Ordinary *Piccalilly* may be converted into a very good Chow-Chow by a liberal addition of curry powder to the other ingredients.

Chowder.—See *Clam-Chowder.*

Christmas Fancies.—Under this name a considerable business is done in certain emblematic and decorative plants, branches, berries, etc. Holly and mistletoe, etc., contribute materially to the attraction of many other shops besides those devoted chiefly to the products of the garden.

The custom of hanging-up emblematic plants, such as mistletoe, *viscum album*, on Christmas Eve is of Druidical origin. They regarded it with extreme reverence and wondrous healing powers. The cutting of it from the oak was an occasion of great ceremony. When the oak was reached on which the mistletoe grew the white bulls were bound to the tree, and the chief Druid, clothed in white (the emblem of purity), ascended, and with a golden knife cut the sacred plant, which was caught by another priest in the folds of his robe. Bulls, and even human creatures, were then sacrificed as a propitiation to their gods. Festivities of various kinds followed, after which the mistletoe was distributed among the people, who hung up the sprays over the entrances to their dwellings as a

mark of gratitude to the sylvan deities during the season of frost and cold.

Mistletoe is a parasitic plant, growing on apple, willow, poplar, and other trees, the seed being transported by the agency of birds.

The growth of the mistletoe is rather curious. It may be said to exist in co-operation with the tree that supports it, because if the tree nourishes it partly during the summer, the mistletoe nourishes the tree in winter.

The growth of the mistletoe on the oak is now of extremely rare occurrence, but in the orchards of the West Midland counties of England—Gloucester and Worcester especially — the plant flourishes on the apple trees; these being made to produce far more mistletoe than apples. Large quantities are cut at the Christmas season and despatched to London and other places from all the Western counties, while it comes by the hundred crates every December, *viâ* Cherbourg, St. Malo, and Granville from the Normandy orchards. The plants used for decorative purposes at Christmastime are naturally emblematic. The *laurel* or *bay* has from the time of the ancient Romans been dedicated to joyful commemorations, and its branches have been used as the emblems of victory and joy. Its use is, therefore, obvious at the Christmas season, when gladness and peace abound. The *holly* is held in peculiar veneration at this period of the year. So much has it identified itself with the season that we very often speak of it as "Christmas." This plant has no doubt recommended itself for decoration because of its attractiveness, with its smooth and shining exterior and red berries, suggestive also of wisdom in many ways. Well berried bushes, which for the birds denote a severe winter, fetch good prices. Most of that reaching the London markets is sent from Surrey; but all parts of the country contribute to the annual demand.

The *rosemary*, besides its rich fragrance, was supposed to possess many occult virtues, and was used on occasions of both rejoicing and mourning. It was believed to clear the head, strengthen the memory, make touching appeals to the heart, give hope and joy, and a thousand things. For those reasons it was borne both at weddings and at funerals.

Christmas Poultry.—See *Poultry Trade, Turkeys*, etc.

Chuan.—A small seed of yellowish green colour resembling worm-seed, brought from the Levant, and chiefly used in making carmine.

Chufas or **Tiger Nuts**—These nuts, also called *Earth Almonds*, are the edible tubers or fibrous bulbs of *Cyperus esculentes*, a sedge-like plant, native of the Mediterranean shores, and are now cultivated in many regions, especially Spain. Chufa is the Spanish word for tiger. They have a nutty taste, and are very sweet. The juice is largely used in flavouring margarines and the lower priced "condensed milks."

Chumps.—See *Dutch Vegetables.*

Chuno.—A national dish which the Peruvians make from frozen potatoes. The potatoes are steeped for a little while in water, then exposed for a few days to a sharp frost, washed and rubbed. By this method the peel becomes detached, and the starchy matters are dried in the sun or in an oven. The dried tubers are then cut in thin slices and baked, and afterwards eaten, with the addition of Spanish pepper.

Churchman's Patent Chocolate.—This is a very old brand of chocolate, probably the oldest in existence. Mr. Churchman patented his production about 150 years ago. The works were at the Castle Mills, Bristol, where he used a *water engine*. He was succeeded by Joseph Fry and John Vaughan, predecessors of the present firm of J. S. Fry & Sons.

Churl's Treacle.—See *Garlic.*

Churrus or **Charas.**—See *Bhang.*

Chutney or **Chutnee.**—A variety of Indian pickles, condiments, or relishes compounded of sweets and acids, mild and sour. Very popular throughout India. Bombay is a great centre for their manufacture, but imitations are

produced in England; the latter are made from pickled or dried materials, and often very coarse, fibry, and inferior.

The ordinary ingredients used in India are ripe fruits and other horticultural products grown in India, such as mangoes, tamarinds, cooca-nuts, raisins, etc., while in fresh condition, with spices, sour herbs, cayenne, and lime-juice. They are usually either cut up in slices or pounded and boiled together, and either used immediately with curries or stews, or put up in pint or quart bottles for keeping.

To make an *Imitation Chutney*:—Take 1lb. brown sugar, ¼lb. powdered white sugar, ½lb. salt, 2 oz. garlic, ¼lb. onions, ½lb. mustard seed, ½lb. raisins (stoned and chopped fine), 1½ ozs. ground cayenne, 3 pints vinegar, and 5lbs. apples.

The mustard seed should first be washed and dried, the garlic, onions, and apples peeled, sliced, and reduced to paste in a mortar, then boiled into a pulp with the vinegar. When cold mix in all the other ingredients, and blend them well together. Bottle in wide-necked bottles, cork well, and keep air-tight for three or six months till required for use.

Of course all imitations are much inferior in aroma to the genuine, made from the widely-famed gardens of the East. The best known kinds are described under their alphabetical headings: — *Bengal Chutney*, *Cashmere Chutney*, *Colonel Skinner's Chutney*, *Lucknow Chutney*, *Madras Chutney*, *Mango Chutney*, *Tamarind Chutney*, and *Tirhoot Chutney*.

Calcutta Howrah Chutney is of a mild character, composed of several mixed fruits cut into small pieces.

Indian Mixed Fruit Chutney is very similar, but rather sweeter and warmer; so is *Pine-apple Chutney*, only this last is much sweeter.

Rajahas Chutney. — A delicious variety in paste or pulp form, made moderately sweet and warm.

Major Grey Chutney is a pale, clear kind cut in slices, sweet and mild.

Sliced Chutney is, as its name implies, cut into slices, but is moderately hot and sour.

Chutneys are mostly used with cold meats, but they may also be used advantageously with hot meats, chops, steaks, hashes, fish, etc.

Special Importers.—Charles Cocks & Co., Reading; Allen Jeeves & Sons, Seddington, Sandy, Beds; J. A. Sharwood & Co., Ltd., St. George's House, London, E.C.—the largest dealers in the world.

Chutney Sauce.—A very good one is made as follows:—Take 2 quarts vinegar, 3 quarts green gooseberries (full grown); boil the berries in 3 pints of the vinegar till tender, and into the other pint of vinegar mix 1lb. of sugar to form a syrup. Then take ¾lb. of salt, ½lb. currants, 2 ozs. fresh chillies, 2 ozs. garlic, 1 oz. ground ginger, 1 oz. grated nutmeg, 1 oz. ground allspice, 2 ozs. mustard, a teaspoonful of ground mace, and 2 of cayenne.

The garlic and chillies to be pounded in a mortar, and all the ingredients to be well mashed up and strained through a sieve. Add 2 ozs. of ground turmeric to colour it. Fill into wide-mouthed bottles and cork well. It may be used in an hour or will keep for years.

Cibol or **Ciboul.** — See *Shallots*, *Leeks*, etc.

Cider or **Cyder.** — F. *Cidre;* G. *Zider*, *Apfelwein;* It. *Cidro;* Rus. *Kvas;* Sp. *Cidra;* W. *Afel-lyn.*

The fermented juice of apples. Three sorts of apples—sweet, bitter, and sour—are commonly used in cider-making. The first gives flavour, the second body, and the other the necessary acidity. Either of the two first sorts may be used alone, but not so the third; the best cider is made from a judicious blending of the whole three sorts.

The production of this beverage dates back to ancient history. The Romans, as also indeed the Greeks and Egyptians, had their wines made from apples and pears, and the contemporaries of Pliny and Diodorus Siculus valued highly the juice of the apples from Gaul.

In the 6th century cider had become a common drink, especially among the lower classes, though not exclusively with them, for St. Radegonde, Queen of France, held it in high esteem, and had it served daily at her own table.

The Biscayens also knew cider and obtained grafts of various kinds of apples, the juice of which was found superior to similar productions of the period. It is now one of the chief productions of the Pasajes province in Spain.

Normandy was the first to popularise cider as a drink. Thence it spread to Picardy, Flanders, Germany, Russia, England, and finally to America. Ever since the 14th century the Norman juices have been the most celebrated, and even to-day her ciders are considered the finest in the world. Nearly all the cider made in France is in the departments which have been formed out of the ancient provinces of Normandy and Brittany.

It is a curious fact that the least juicy apples afford the best cider, and the apples most suitable are the late kinds, rough, sour, and disagreeable to the taste.

Acid apples give an abundant clear and light juice, but the cider which is made from them is liable to turn black, and it is weak and generally difficult to keep.

Sweet apples also give an abundance of clear cider which is agreeable to the palate as long as it is new; but as soon as the sugar is absorbed it ferments, and goes sour, contracting a bitter taste, which renders it flat and unpleasant for a drink. Another kind of sweet apple gives as clear a liquid as the preceding, but the presence of a quantity of alcohol in the sugar renders it stronger and better adapted for keeping. Finally, *bitter* or *sour* apples give the most generous cider, which is of a fine colour and keeps well. The cider obtained from a blending of bitter or sour with sweet apples is very light and agreeable, and keeps fairly well.

After sugar, tannin is the most important constituent of an apple, and it plays a role of incontestable utility. Bitter apples contain the most tannin. They should be just ripe, because the amount of sugar in ripe apples is 11·0 while in unripe it is but 4·9, and in over ripe only 7·91. They are generally gathered in September—the nearer to cold weather the better the cider will keep—and left a few days to mellow, then ground in a mill, and the pulp or "must" is squeezed in a press through canvas or hair bags. The juice runs into a cask with an enlarged bung-hole and is made to ferment and froth over for four to ten days till most of the yeast has gone off, after which it is racked off into clean casks or bottles, kept air-tight, and allowed to rest till spring when it is ready for drinking. Good cider contains 5 to 10 per cent. of alcohol. *Hard Cider* is cider which has lost its sweetness from over-fermentation.

German Champagne is merely a sweet sort of sparkling beverage, manufactured out of American or French apples by an addition of water and with the help of certain chemicals.

Champagne Cider is described under its own heading.

Sweet Cider.—Cider before fermentation, or which has fermented very little.

Water Cider or *Ciderkin* is a kind of weak cider made by adding to the apple pulp or *marc* half its weight of water, and then expressing the liquor a second time.

In England about 12,000,000 gallons are made yearly, the counties of Hereford, Worcester, Devon, Somerset, Gloucester, and Norfolk being most noted, where a ton of apples, value £5 to £10, will produce about 200 gallons of cider.

Cider is very popular in France, and is the common drink in the north-western part, from Amiens to Nantes and Brest, the annual yield being about 250,000,000 gallons. That from Normandy is often sold as *arrack*. Apples in France are usually about £5 per ton, but large quantities of American dried apples are also used in cider-making, because they are richer in saccharine matter than green apples, also cheaper in price and transit. The

nature of the soil has, doubtless, much to do with the excellence of ciders, but science and art have also lent their aid. Normandy apples are now bought up largely by German cider-makers in Frankfort, and the product then exported to all parts of the world. Germany grows hardly any apples, but she exports ten times as much cider as France!

Very good cider is also made in Cork, Waterford, and other counties in Ireland. Large quantities have been sent to this country from the United States these last few years, where the best is made from the Hughes or Virginian crab-apples. These are little more than twice the size of wild crabs, are not remarkable for quantity of juice, and are entirely destitute of any good edible qualities, but produce a cider that will command double the price of that made from the best table apples. The *Harrison*, a yellow apple, twice as large as the above, comes next as a cider apple, and makes an excellent quality.

From time immemorial there have been districts in England in which the wine of the country has been *cider*, but this has now almost ceased to be; and the decay of this once flourishing industry is much to be lamented. The kinds of apples which were once renowned for cider-making are now almost unknown, save in the orchards and gardens of a few; whilst farmers and others have to a very great extent given up the production of this healthy and exhilarating homely beverage.

The farmers of Herefordshire are not now making such good cider as they did years ago, although that county is particularly suited to the fruit. They do not take sufficient trouble to keep the varieties separate when grinding up the apples, or to throw out the rotten fruit, but usually smash all up together.

In the Weald of Kent they seem to have lost the true art of cider-making, for they put sugar in it, which is a great mistake. About Swanley and certain other parts of Kent good cider is made, though different in character to that of West-country make.

In 1894 Mr. Radcliffe Cooke, M.P. (a Herefordshire man), and Sir George Birdwood addressed letters to the *Times* on the subject of cider and cider-making, which called forth various suggestions and inquiries, resulting in the founding of the "National Association of Cider Makers." In September and November, 1895, the subject again cropped up in the same journal, showing that an endeavour was being made to turn Kent into a cider county. Technical education has suggested that the cider-maker should know something of the theory of fermentation and the scientific principles which underlie the business, for some makers have even made the mistake of selling the pick of their apples and using the bruised fruit and windfalls for cider. The old people, it is true, worked by rule of thumb, but recipes were handed down from generation to generation, and when a Devonshire man spoke of his cider apples, he meant not merely a particular sort but the pick of that sort.

Unfortunately cider travels badly, hence in our large towns most of it is mixed with water, treacle, alum, etc. The best is generally sold in bottle.

Cider should never be allowed to freeze and thaw. When it has accidentally become frozen the liquid portion should be drawn off into other barrels and the ice thrown away.

As all our best cider manufacturers know, a good article cannot be made from defective apples, and the picking up of all sorts with leaves and dirt attached is a foolish economy and cannot be too severely condemned. It would pay the cider-maker much better to reject all unripe and unsound fruit, also to wash their apples and clean and dry them in the sun until they are a little wilted, for the more water that can be removed from them at this stage the better the cider will be.

Why should the good old English beverages of cider and perry be unobtainable in our public-houses and restaurants? Tea, coffee, cocoa, mineral waters, ales, beers, wines, and spirits stare in the face the thirsty wayfarers

everywhere, but "Cider and Perry on draught here" is far too seldom seen. The great mass of the licensed houses being "tied" to brewers or distillers, only what they make can be sold in these bars, and so cider and perry are boycotted.

When early in the seventies the late Dr. Bull and his compatriots adventured into the north of France from Hereford, taking with them the finest specimens of apples and pears and the cider and perry produced from English orchards, they left behind them a grand industry.

There is a good deal of malic acid in sour cider, but it is perfectly harmless. Cider is regarded as an excellent beverage for persons of a gouty tendency, and it is stated that rheumatism is far less prevalent in Herefordshire, Devon, and Somerset than where beer is the popular beverage.

Cider Brandy. — A cordial made from the residuum of apples and pears after the cider or perry has been extracted.

Ciderkin or **Water Cider.** — F. *Amelion.* (See *Cider.*)

Cigarettes or **Cigarillos.** — G. *Cigaretten;* It. *Cigaretti;* Port. *Cigarros;* Sp. *Cigarillos.*

There are all kinds of fancy names for cigarettes, but the tobaccos ordinarily used in them are only two, namely, Turkish and Virginian. "Egyptian cigarettes," so-called, are merely made in Cavio or Alexandria from Turkish tobacco.

The bulk of present day cigarette smokers are, however, not very critical as to quality. Quantity is the greater consideration. A few years ago every cigarette smoker made his own, but now they are mostly made by an elaborate system of automatic machinery which turns them out more cheaply than by hand—although the latter are usually preferred. A single workman with a machine is said to be able to turn out about 10,000 cigarettes in ten hours, whereas by hand it requires a clever hand to make 1,500 a day. The machines cut the paper—made very thin and tough specially for the purpose—gum its edge, measure out the proper quantity of tobacco, wrap it up, make the gummed edges stick, cut the ends, and pack the cigarettes in boxes.

Cuban "cigarillos" are usually made in large factories at Havannah, the workers being convicts (Africans, Congos, Mulattos, Chinese, Spanish sailors, etc.) contracted for with the Government. Each works and smokes with a heavy chain dangling from his waist and attached to his ankle.

Large quantities of cigarettes also come from Roumania, where labour is very cheap, and the tobacco in these is much milder than the American growths.

According to the *Monde Economique*, potato leaves have recently come into competition with tobacco for making cigarettes in the Argentine Republic.

Cigarettes have lately come into use very extensively in this country, although they are much more deleterious to health than tobacco smoked in pipes or cigars.

There is a partiality for tipped cigarettes, especially those tipped with "gold," partly because the "tip" prevents the paper from adhering to the lips, but it is said that imitation gold and silver tips are injurious to the smoker.

Many of the low-priced kinds of cigarettes are made up chiefly, if not entirely, of paper which has been steeped in tobacco water and then finely shredded to imitate tobacco. Old cigar ends are also used.

Cigars or **Segars.**—F. *Cigars;* G. *Cigarren;* Port. *Charutos;* Sp. *Cigarros puros.*

These are of Spanish origin. The best are made by hand and usually composed of two parts—a central mass formed of pieces of leaf of uniform quality, known as *fillers*, placed longitudinally so that the smoke may be freely drawn, and a covering formed of selected leaf of the finest colour called the *wrapper.* The only tools required are a short-bladed sharp knife, an emulsion of gum, and a square wooden disc or cutting board. A portion of the perfect leaf is first shaped to form the inner and outer wrappers, then a bunch

of fillers is moulded in the hand and rolled up tightly in the wrappers, the pointed end being secured by gumming and the other cut off straight. Old cigar stumps collected in the streets, smoke rooms, and other places of public resort are often boiled and afterwards cut up and used as "filling" for cheap cigars (and cigarettes); while the liquor is utilised as tobacco water in various ways. In America hard wooden moulds lined with tin are used for rolling the fillers for cigars, and machines for cutting and sifting scrap as stuffing are often used for making what are called "scrap-made" cigars.

It is a curious fact that the best and choicest cigars are made by men. Even in England makers do not care to employ female work-hands on any very special or ordered goods, for there is a peculiar knack in arranging the "fillers" (or inside contents) of a cigar in such a way as to bring out the flavour, and women do not seem to have acquired it. Of course there are thousands of work girls engaged in the trade, but these are only employed in turning out the inferior quality goods, where the exact lay of the tobacco is not of prime importance. For instance, every leaf must be so placed inside the cigar that the aroma cells, as they burst in the smoking, shall send their fragrance towards the mouth instead of in the direction of the outer air. As each leaf varies in its arrangement of cells there is all the difference between a cigar made by a man who appreciates this, and the one manufactured by a factory girl, working by rule of thumb. Experts pride themselves on their quickness in picking out a "female" cigar (as they term it), for the veining or direction of the outer coat will also be inexplicable, and the cigar will not burn so evenly. This is all the more surprising, as in the parallel trade of cigarette making females prove themselves the more expert and deft fingered.

Many of the cigars made in the United States are of Mexican tobacco, yet the statement is often made that these cigars are made of the Cuban leaf.

Mexican Cigars mostly come from Vera Cruz, where there are several large factories turning out very fine qualities. The leaf, grown from Havanna seed, is rich in colour, of excellent texture, good body, and exquisite aroma.

Continental Cigars.—These do not appear to possess any superiority over British manufacture, unless it be a firm at Antwerp, which has long enjoyed considerable reputation for its cigars made of Havanna leaf and after Cuban methods.

Havanna cigars of the choicest make surpass all others. They are all professedly made of the best Cuban tobacco; but the growth of this quality is limited, and although excellent for smoking it is very rough; so that the leaf used as wrappers for the finest quality of cigars is grown in Connecticut, and, indeed, most of the cigars now made in Havanna are really made of Mexican or American tobaccos, which are regularly shipped to Cuba for the purpose.

Mexican leaf does not, however, suit for outside wrappers. A short time ago *Mexican made cigars* were exported, but they failed to give satisfaction, owing to the remarkable quick ripening of the tobacco during the short transit even from Vera Cruz to New York. Claros became "*maduros*" or even "*oscuros.*" It was found that boxes marked "Colorado," "Colorado Claro," and even "Claro," when opened, contained "maduros" or "oscuros." Practically no "wrapper" leaf is now grown in Mexica, but all "filler." This is a virtue to those who like a strong cigar, easily smoked, but it is a defect for the general smoker who likes a milder article which he can smoke all day.

But Mexican leaf may now be said to have taken the place formerly held by that of Cuba in the manufacture of three-fourths of these cigars. Curious to say, tobacco of the Havanna quality can only be raised in Mexico, its tobacco region being 100 times the extent of Cuba and the soil from 8 to 20 or 30 feet deep.

Most of the Continental so-called "*Havanna cigars*" are made by children, and numbers of cases of

cigars sold in Europe as of Cuban origin come from Key West, off Florida, where there are about 125 factories employing 6,000 to 7,000 workmen. On piece-work a man there makes about 1,000 a week, receiving 14 to 40 dollars per 1,000 according to brand. Sorters, testers, and packers get as much as 30 dollars a week.

Manila Cigars.—These old favourites still retain their charm for smokers. Grown in the Philippines, the leaf is soft and delicate, smooth, but quite tenacious, and burns to a fine ash. These cigars used to be all made by the natives at their own homes, but now there are several factories in the islands, and labour is very cheap. Manilas are usually rolled straight, and may be had in our large towns at about 4/- per lb., which, with duty 5/- per lb., means 9/- per 100 cigars to retail at 2d. each. The 3d. brands, "Capitan General," "Hessiana," etc., have long been esteemed for their silky texture, sweetness, and rich aroma; and, instead of being packed in boxes of 250's and 500's only, are now to be had in 100's. (See also *Manila Tobacco.*)

The names and descriptions of cigars, even those of English manfacture, usually appear in foreign languages, chiefly Spanish. There is consequently much misconception as to the meaning of the words used. It should be noticed the following refer to size or shape only:—

Concha or Conchas	Planters
Concha Finos	Princesa
Concha Frabucos	Princesa Reinas
Concha Victoria	Principe
Conchitas	Quadrados
Elegantes	Reg Princesas
Imperiales	Regalia Brittannia
Infantes	Regalia Preciosa
Londres	Regalia Reinas
Londres Chico	Reina Victoria
Manilas	Reinas
Media Regalia	Trabucos
Non Plus Ultra	Victorias

Colours are indicated by *Madura* (dark and strong), *Madura Colorado* (light brown), *Colorado* (lighter brown), *Colorado Claro* (very light and mild). Cigar boxes are usually made of Spanish cedar grown in Cuba. This wood always retains the flavour of good cigars, and some connoisseurs say it improves it. The boxes also are often marked *Flora Fina* (fine flower), meaning first quality, or *Flor* (second quality); but these terms are now used indiscriminately, and are merely fanciful embellishments.

Britishers are becoming, year by year, more and more a cigar consuming people, but it is not creditable to British firms that they should so slavishly copy the brands of Mexico and elsewhere as they do. Imitation is the sincerest form of flattery, no doubt, but more originality would be preferable.

The best Havanna cigars are too costly for most people, so that Europe caters for the average smoker of moderate means, and the Continent sends us about 80 million cigars every year. For in the United Kingdom cigars have to be made under the eye of Excise officers in specially licensed premises and under cast-iron factory Acts; but on the Continent most of the cheap cigars are made in domestic garrets or unhealthy cellars. One might think this would prejudice British smokers in favour of the home article, but quite the contrary. British cigars are not fashionable, and if purchased, the label or name on the box must be erased or altered. The average smoker pretends he cannot enjoy a cigar made in England, yet call it a Havanna cigar, and he will discourse for hours on its peculiar merits and delights.

Nevertheless, the quantity and value of British cigars has nearly doubled within the last 20 years, and really a cigar made, for instance, from high-class Indian fillers, blended with a smooth and nice Sumatra or Borneo wrapper of fine quality, can scarcely be beaten.

The 2d. cigar, weighing 1¼lbs. to the 100, is the most popular, and the chief reproach against them is not so much inferiority of flavour, but that the insides are too often stuffed with odds and ends of leaf instead of using long fillers, which reach from one end of the cigar to the other.

Indian Cigars.—In place of the long *Trichinopoly Cigars*—with a straw

through the middle, the *Supers* and *Musters*—strong, black, and coarse, of some 30 years ago, we now receive from India the mild "Flor de Dindigul," which, made in the town of Dindigul, near Calcutta, in shape, if not in flavour, are quite equal to Havanna cigars. So also are some of the *Borneo Cigars*, especially the brand "*La Flor de Brandigas*," which have become special favourites, and are only about half the price. India seems better adapted than England for tobacco and cigar production, for the leaf may be of the best, yet a damp climate materially affects its virtue, when cigars are made of it. The leaves used for the outside wrappers of British cigars depending more on the appearance than the taste—more on good looks than flavour—are nearly all grown in Borneo.

Cigar Importers.—E. H. Skilton, 6 Wellington Street, Hull; The General Shipping Co., Ltd., 1 Lombard Court, London, E.C. (see adv. end of book).

Cinchona. —See *Quinine*.

Cinnamon. — Ar. *Darsini*; D. *Kaneel*; F. *Cannelle*; G. *Zimmet, Kanehl*; It. *Cannella*; Per. *Darchinie*; Port. *Canella*; Sp. *Agriaz, Canela*; W. *Canel*. (See also *Canica*.)

In Austria, Germany, Hungary, and Russia, cassia bark is official under the name of Cinnamon; and in the Danish, Dutch, Spanish, Swiss, and United States Pharmacopœias both cinnamon and cassia are official under the name of Cinnamon; but in the United Kingdom cinnamon must be the bark of *Cinnamomum zeylanicum*. This is an aromatic species of laurel which grows in Ceylon, Sumatra, Borneo, and is also cultivated in Guinea, St. Vincent, Jamaica, Brazil, Mauritius, Pondicherry, Guadeloupe, and Java. The tree grows 20 to 30 feet high, and has a trunk about 18 inches thick; the leaves are oval-shaped, 4 to 6 inches long, and the flowers are of a silky-grey colour outside and of pale yellow internally. The fruit is of acorn shape, and is brown when ripe. The trees reared from seed commence yielding at four years old, but arrive at their prime when about twelve, and will continue producing bark till perhaps 200 years old. In preparing the bark for market the epidermis is scraped away, and the inner bark is cut up in slices, and as they dry in the sun these curl up into rolls, the smaller quills being afterwards inserted into the larger quills. They are finally made up into bundles or bales, about 90lbs. each, and wrapped in double gunnies.

BRANCH OF CINNAMON TREE.

The bundles are about 100 cm. in length by 6 to 9 mm. in diameter, made up of quills about 30 cm. long, the pieces being made to overlap, in order to make up the bundles of uniform length and the smaller and broken pieces being packed in the interior.

There are at least ten different varieties of cinnamon bark, and that known by the Cinghalese name of *Penne* or *Rasse kuroondu* is said to be of superior quality.

Chinese Cinnamon is of two kinds. That produced in Kwantung and Kwangsi is merely the bark of old cassia trees; but a very excellent kind is exported from the Laos States, controlled by France, and brings a very high price on arrival in Canton, although nothing definite seems to be known as to its

botanical source, *i.e.*, whether obtained from the cassia tree or from a distant species.

The finest cinnamon we receive is that produced in Ceylon, and most of ours comes from there. It should be of a light yellow colour, almost thin as paper, pliable (first bending and then breaking splintery), smooth, and shiny.

The outer corky layer having been removed during the process of preparation, only traces of the cork cells remain. The quills are marked externally with fine lines, pale and wavy, and with small scars or holes, indicating the position of lateral twigs or leaves. On the inner surface the colour is rather darker. The smallest quills are the finest, and should have an agreeable warm, aromatic flavour with a mild, sweetish taste. When chewed it becomes soft and seems to melt, is not so pungent as to bite the tongue, and is not followed by any after taste. Every bundle should be carefully examined, as the true is often adulterated with inferior barks.

The one most resembling it externally is *C. obtusifolium*, but this is in larger quills, has a very fibrous fracture, and there is a flavour as of coriander.

Cassia Bark is often mixed off as cinnamon, but it may be detected by its being thicker, coarser, often covered with outer cork, and darker, and its fracture, which is short and resinous; its flavour also is hotter and more biting than cinnamon, and the pieces are rarely inrolled in each other. Cinnamon is also sometimes adulterated with clove bark and stalks, also different flowers.

Ceylon Cinnamon is grown chiefly in the neighbourhood of Colombo, although a good amount is also obtained from wild jungle bushes in the hill forests. Its collection is in the hands of a distinct caste of Ceylonese. It is often mixed with guava bark and weighted with sand.

Cinnamon "Chips" or *"Quillings"* consist of inferior fragments, clippings, cuttings, or trimmings of the shoots, and other small pieces, and usually have bits of whitish wood attached to them. Chips are mostly distilled for oil or made into ground cinnamon, and are usually sold at about one-tenth the price of genuine cinnamon.

Cinnamon is imported mostly in bales, but also in bags, parcels, boxes, and ballots.

White, Wild, or *Bastard Cinnamon* is the bark of the *Canella alba*, flourishing in the West Indies, Bahamas, and in Florida. The outer skin, or cortex, being white or silvery in appearance, and often but imperfectly removed from the inner aromatic bark, has given the name to this variety of cinnamon. The flavour is very agreeable, but more pungent and bitter than the true cinnamon. The sticks or "quills" also are not so perfectly formed.

Ground Cinnamon is sometimes adulterated with the powdered wood or twigs of the tree, and is noticeable by the presence of white particles. It is also largely adulterated with cassia and inferior species, and in this state there seems no reliable means of distinguishing one from the other, except by comparing the flavour, that of cassia being coarser and somewhat camphoraceus. Cassia is also mucilaginous. Powdered walnut shell is another modern adulterant of this spice. It is best detected by a skilful microscopist. Many persons think that Cinnamon and Cassia are obtained from the same tree, that the *outer* bark is Cassia and the *inner* bark Cinnamon; but this is not so, for although the Cassia tree is an allied species of the same family, no true cinnamon is ever found on the Cassia tree. Cinnamon may always be fairly well judged by the taste.

Cinnamon Essence.—For culinary purposes. The best is made from the essential oil of cinnamon, say one part mixed with 12 or 18 parts of rectified spirit, and agitated until perfectly united; sometimes 2 parts of carbonate of magnesium are added. Rub the oil with the magnesia. After filtering and settling for twelve hours, the clear portion will be ready for use.

Essence of cassia is often sold for it.

For a long time the Dutch monopolised the trade in cinnamon, Amsterdam being the principal sale mart; but after the British were in possession of Ceylon the

cinnamon trade fell into the hands of the East India Company.

Essence of Cinnamon is said to be a useful safeguard against influenza, because no living disease germ can resist for more than a few hours its antiseptic power.

Cinnamon Oil.—A volatile and extremely pungent essential oil of yellowish red colour, and mostly prepared in Ceylon by grinding the small pieces of inferior and waste bark, leaves or roots, soaking them several days in sea-water and then distilling.

A peculiarity, however, of the true variety (*Cinnamomum zeylanicum*) is that it really contains quite different volatile constituents in its roots, leaves, and bark, camphor being most prominent in the root oil, eugenol in that from the leaves, while the bark contains a large amount of cinnamic aldehyde and 6 to 8 per cent. of eugenol. The oil obtained from the leaves is somewhat inferior, and only valued at about 4d. an ounce; but the flowers yield an oil fully equal to that of the bark.

Genuine cinnamon oil has a delicious aroma, and is very stimulating. It fetches 1/6 to 2/- an ounce; but is often adulterated with rectified spirit or with oil of cassia. The Chinese is said to be the best and the Brazilian the worst.

Cinnamon Soap. — F. *Savon à l'Huile de Cannelle.*

A superior kind of toilet soap, composed of equal quantities of pure palm soap and tallow soap, coloured and scented. The perfume is usually made of 8 parts of oil of cinnamon, 2 parts of sassafras, and 3 parts of bergamot, but oil of cassia is often substituted for the more costly oil of cinnamon.

Citrate of Lime.—Port. and Sp. *Citrato de Lima.*

This is now considered the safest form in which the acid principle can be conveyed, and it is now mostly prepared in Italy, where citric fruits have long been very plentiful, and where a native chalk has been found fairly suitable for the purpose of manufacture; although the Creta Inglese, or Craie de Meudon, were, until very lately, considered not only the best sort of chalk for the purpose, but the only suitable kind. 2,000 lemons will yield about 80 kilogrammes of citrate of lime.

The process of manufacture is as follows:—The raw juice of inferior lemons (*i.e.*, lemons which could not be exported as green fruit) is mixed at a temperature of 80° with sufficient whiting to form a paste, wherein all the acidity of the lemons has been absorbed by the whiting. This paste is then placed in white canvas bags, which are piled up and subjected to great pressure to extract the valueless liquid part, all the essential properties of the lemon juice being retained in the chalk. The substance thus obtained is next spread out in tiers in drying chambers, artificially heated, until it crumbles away into powder, which is the citrate of lime as known in commerce. It is generally shipped in tierces containing about 10 cwts.

Citrate of Magnesia.—F. *Citrate de Magnésie;* G. *Citronsäueres Magnesia;* It. *Citrato di Magnesia;* Sp. *Citrato de Magnesia.*

The granular effervescent passing under this name is not really a citrate of magnesia at all, but a mixture of tartaric and citric acids, with bi-carbonate of soda, sugar, and a mere trace of magnesium salt. Most of the manufacturers are now careful to label it merely as "*Effervescing Citrate.*" The ordinary proportions are 17 parts bi-carbonate of soda, 6 parts citric acid, 9 parts tartaric acid, 6 parts white sugar. The active ingredient is, as stated, a mere trace of magnesium salt. In preparing it the soda is heated until it loses about 60 per cent. of its weight and rendered anhydrous. On the addition of the citric acid and by the aid of heat, over a water bath, a stiff paste is formed. This is then heated to about 212° F., which drives off the moisture till it cakes. It is then well stirred, carefully triturated, and cooled till the granules become quite cold and brittle. It is then put through a riddle, gently dried, and bottled. The final drying is best

done in the sun, as the preparation should be of normal temperature when bottled. On the addition of water it effervesces, and is an excellent aperient. Dose: 2 teaspoonfuls in half a tumbler of cold water. Made half strength, it forms a pleasant and agreeable cooling draught for children as well as adults. It should be kept in a dry place.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Citric Acid or **Salt of Lemons.**—F. *Acide citrique*; G. *Citronensäure*; It. and Sp. *Acido citrico*; Lat. *Acidum Limonorum.*

A concentrated acid obtained from several citrus fruits, but chiefly from the juice of lemons and limes, which owe their sourness to it. Messina is now a great trade centre for this article. In its crystallised state it is colourless, inodorous, very sharp in taste, and readily soluble in water.

In manufacturing it, the crude juice is first allowed to ferment, so as to separate the mucilaginous matter, then it is filtered, and the clear liquid is neutralised with carbonate of lime. (See *Citrate of lime.*)

This insoluble citrate of lime is next collected, washed, decomposed by sulphuric acid (say 9 ozs. of sulphuric acid to 1 ounce of chalk), and the fluid thus obtained is strained through a cloth strainer, and exposed in shallow pans, so that it may crystallise by spontaneous evaporation into colourless prisms. Eight ounces of citric acid may be obtained from each gallon of raw lemon juice, and one ounce of the citric acid crystals thus obtained is about equal to a pint of lemon juice.

Citric acid is also put up in a liquid form combined, more or less, with mucilage and sugar, which renders it liable to ferment; therefore, if wanted for keeping a length of time the solid acid is to be preferred.

The chief use of citric acid is to prevent sea-scurvy, but it is also very cooling, and gives a refreshing fruity taste to lemonade and other aerated beverages. It is also used in making confectionery drops, lozenges, etc. Often adulterated with tartaric acid.

Citron Peel, Rings, etc.—Du. *Sukkat*; F. *Citronat vert*; Ger. *Succade*; It. *Confetti di Cedro*; Port. *Pel de limao*; Sp. *Piel de limon.*

Citron peel consists of the thick and tender rinds of several varieties of the *Citrus medica*, a native of Asia, but now cultivated in most warm climates.

The fruit of some of the larger varieties, such as the *C. macrocarpa*, often weigh as much as 5lbs. each.

CITRON.

The sweet-rinded Citron is prepared in the simplest manner by soaking the rind in warm fresh water for a couple of days, then boiling slowly in more fresh water until tender. The water is then drained off, and the rind put into a thick syrup of the best white sugar, and boiled slowly and as long as possible without crystallising the sugar. The pieces of peel are then allowed to cool, then placed in fresh syrup, and the boiling repeated. The pieces are now almost transparent, and have absorbed all the sugar they will hold, so they are finally placed on shallow trays and dried in a warm, airy oven.

The bitter Citrons are gathered quite green and tender, cut in halves or quarters, freed of pulp, and then put into a vessel of strong brine and left there for a month. The salt water is then poured off and fresh put on. This process extracts the bitter principle from the fruit, the salt being afterwards extracted by the fresh cold water. The peel is then boiled in fresh water until a fork will easily pass through it. It is next drained, placed in an earthen jar, and white sugar syrup poured over it, and allowed to stand a few days, then boiled again, and the process repeated until it will take up no more sugar. It is finally dried, either on trays as above described, or in an "evaporator," and is generally flavoured with lemon-peel.

Citron peel is imported either ready candied from Madeira, etc., where the best quality is prepared in large quantities, or in salt and water, to be afterwards candied in this country or used without candying.

Citron peel is less acid than the lime or lemon fruits, has a tendency to prevent vomiting, and excites the appetite; hence its value in rich cakes, Christmas puddings, sweetmeats, punch, negus, etc.

Citrons.—F. *Citrons;* G. *Citronen;* Port. *Limoes;* Sp. *Limones.* (See also *Cedratur*, *Candied Peels*, etc.)

The name "Citron" is said to be from the town of Citron, in Judea.

C. aurantium probably so called from the Latin *aurum* (gold), from the colour of the fruit.

C. limetta (the lime) is derived from the Persian *Limu*, the fruit having been introduced into Europe from Central Asia.

C. bergamia is only a variety of the above. It yields the bergamot, a fruit similar in shape to the bergamot pear, and takes its name from Bergamo, a town in North Italy.

C. medica.—The name of this species is probably derived from the Arabic *Laymum*, a lemon. *Medica* is the Latin for Median or Assyrian, which appears to indicate that the lemon was originally obtained from the East.

Citrons are the fruit of a low evergreen tree (*Citrus medicus*) which belongs to the same genus as lime, lemon, shaddock, and orange trees, but most closely resembles the lemon in smell, taste, and colour. The pulp of the fruit is subacid, and the rind thick, spongy, and very fragrant, and much more valuable than that of either lemons or oranges. Twelve well-known varieties are grown in Italy and about twenty in France. Immense quantities are grown in Naples and Sicily—especially on the sunny slopes of Mount Etna; and citron juice made at Messina is exported to all parts of the world. The largest variety are distinguished as *Cedraturs*, and come from Corsica.

Mr. Consul Drummond, writing from Ajaccio, says:—"I attribute the size, aroma, and general superiority of the Corsican citron (or *Cedratur*), which always commands a higher price in the market than that produced in other countries, in a great degree to the soil of Corsica; which, being not only extremely rich in ferruginous qualities, is also strongly impregnated with the various salts and chemicals necessary for the production of the numerous aromatic plants with which the island abounds. This is palpably evident from the natural growth on the hillsides called 'maquis,' consisting, as it does, largely of myrtles, cystus, wild lavender, heaths, arbutus, and a variety of highly-scented plants and shrubs, which in spring and early summer not only impregnate the whole atmosphere with their delicious aroma, but can also be recognised for some distance at sea when the wind is off the shore, thereby causing the land breezes to truly merit the term "balmy" so frequently applied without nearly so much justification. Another requisite for the successful growth of the 'cedrat,' or, as we term it, citron tree, is perfect shelter from the mistral, or north wind, as well as absolute protection from frost; these *desiderata*, together with plenty of sun, and an adequate supply of water having been obtained, a good crop should be looked for if constant care and attention are given, proper manuring at the right seasons carried out, water supplied

artificially morning and evening during the dry season, and the various diseases to which the tree is subject watched for and attended to in due time. The site usually selected in Corsica for the plantation or garden is a sheltered valley, at an altitude of not more than 200 feet to 300 feet above the sea level, facing south or south-west, the north and north-east winds which blow strongly during the winter months having to be carefully guarded against; or an equally well-placed hillside not too much exposed. A constant supply of water is an absolute *sine quâ non*, this being usually ensured by damming a small rivulet, should there be no spring in the neighbourhood, and constructing reservoirs and tanks of size proportional to the area to be planted, which is never large, its extent being usually limited by the local conditions, and extending from a few square yards to as much as three or four acres on rare occasions. A space of at least twelve to sixteen superficial yards being requisite for each tree, naturally limits the number of trees to the space available. In many places in the Cap de Corso district, in the northern peninsula of the island, where the natives are a harder working people and more intelligent than in the south, the gardens are surrounded by high stone walls, divided by inner walls, and again subdivided by stiff fences of dried brushwood, closely wattled. No more than four trees sometimes occupy these small plots, to which the soil has at times been brought in baskets at the cost of much time and labour, in order to take advantage of a sheltered situation. This careful protection is seldom seen in the southern portion of the island, the lazy character of the people resting satisfied with what nature has done for them by way of situation, shelter, and supply of soil and water. Frequently in the Cap de Corso and Balagna districts, the principal fruit-cultivating regions of Corsica, the trees are protected during the winter by branches and mats spread from wall to wall, and in nearly all cases a piece of stiff wattled brushwood is erected as a protection above the walls. The produce of the cedrat tree naturally varies in the amount and size of the fruit, according to the situation of the garden, the soil, and the care and attention devoted to it by the grower; but a single tree of matured growth frequently returns as much as £10 to £12 per annum. These figures alone show how remunerative a culture that of the citron may be made, although the original outlay for making the garden, which is nearly always terraced, frequently involving considerable labour for masonry, walls, etc., as well as for the tank and water conduits, may have been very considerable."

Although very fine citrons are extensively grown in Corsica, the principal candying factories are not in that island, but in Leghorn. Italy enjoys a considerable advantage over Corsica in this manufacture, owing to the fact that the drawback allowed on the sugar used in the manufacturing process almost amounts to an export bounty. The manufacturer pays duty on his sugar in the ordinary way, but the amount of drawback returned is calculated on the amount of sugar estimated to have been used, and the estimate always exceeds the reality. Some years ago the Corsicans claimed a corresponding arrangement from the French Government, in order to enable them to manufacture candied citrons free of sugar duty, and thus protect the culture of the fruit by providing a regular local market for growers, who had been very much at the mercy of the Italian firms. The Government agreed to allow the Corsican manufacturers to conduct their business in bond, but so many restrictions were imposed in the supposed interests of the citron growers as to seriously affect the industry. No sooner were two important factories established and their reputation made than the protected growers adopted a very selfish policy, charging their Corsican customers prices very much in excess of those they accepted from the Italians. This, combined with the Government restrictions, has put the citron candying industry of Corsica into a very unsatisfactory position.

In England we receive most of our citrous fruit from Spain, which, with

Madeira, is the only formidable competitor Italy really has, but the exports from Italy of citrons, oranges, lemons, bergamot, and their products more than double those of Spain, and a great proportion of them goes to the United States.

Trieste is probably the greatest mart in the world for citrons. About 5,000 tons a year arrive there from various points.

Of the two chief kinds there met with one is the large fruit used for preserving and crystallising, the produce of grafted trees; the other, called the "*Citron of the law*," is the natural, unripe, and non-edible fruit of the ungrafted tree.

This latter is the special kind used by Jews in their religious ceremonies during the Feast of Tabernacles.

The fruit for this purpose must be from the ungrafted tree, unblemished, and with the calyx present and uninjured, if possible.

For centuries it has been the custom for Jews from Poland, Russia, and Europe to assemble at Trieste about August, to await the arrival of citrons.

There is always eager competition for perfect specimens of the fruit. Sometimes a single citron of superlative perfection will fetch as much as £3. They are afterwards distributed over the whole of Eastern Europe, Germany, and Poland.

Some 2,000 of these selected "*Citrons of the law*" come to England. The packing is conducted with the greatest pains and after the most careful examination. Each case contains 120 citrons, and each fruit is wrapped round with very soft tow, so as to prevent any injury to the citron or its calyx. The use of citrons from the Ionian Islands is prohibited by the *rabbis*. Considerable quantities without the calyx are exported from Bordighera in Italy, but the value placed on these is far below the citrons with calyx complete.

Madeira exports a large quantity in "pipes," containing 350 to 500 fruits each. Price, f.o.b., 40/- to 60/- a pipe.

Citronella. —This is an essential oil imported almost exclusively for soap-making, hair-oil scenting, and a few similar purposes.

It is obtained from the leaves of the *Andropogon nardus*, a bushy grass growing in Singapore, Ceylon, etc.

In Ceylon two varieties of citronella grass are cultivated, viz., "Maha pangiri" and "Lenabatu pangiri." The first has somewhat broad leaves, and the bushes formed are larger than the second, but the plant soon dies, so that the latter is more popular, although it yields less oil.

Some 70,000 cases come yearly from Ceylon alone, but it is said to be largely adulterated with kerosene, and anything less than 25 per cent. is difficult to detect.

Civit. —French for a hash of wild birds or game.

Clams. —An American term for various kinds of shell-fish of the *mussel* tribe.

"Clam" is in fact a name given in different localities to different bivalve mollusks.

Thus, in New England, about the mouth of the River Helford, it is given to the pidduck, *Pholas dactylus;* in New York and neighbouring States the *Venus mercenaria* are called "hard clams" or "round clams"; *Mya arenaria* being known as the "soft clam" or "long clam."

Clams have become of great importance as an article of food by reason of their great abundance.

A "Clam Bake" is a picnic at which the main dish is one of clams, baked in the primitive Indian fashion. The bivalves are placed in a cavity in the ground, which is first lined with hot stones. The whole is next covered with sea-weed, and the result is one of the most popular dishes in the Amercian *cuisine*.

Considerable feeling has lately been manifested on Puget Sound against the wholesale destruction of the natural clam beds by the packers at Port Angeles. It is reported that, instead of digging for them in the time-honoured manner, the beach is being ploughed up by means of a plough pulled by horses, and the

result of this method of catching will soon result in total annihilation of this toothsome bivalve.

Clam-Chowder.—A popular dish or hotch-potch (especially with fishermen) in America and Newfoundland, consisting of *clams* or sometimes other fish, cut up in small pieces, and boiled with biscuits or crackers, pork, potatoes, onions, etc., in a caldron (F. *Chaudière*).

A "chowder" party is a sea-side picnic, at which chowder is the main dish.

Claret Wines.—(See also *Bordeaux Wines.*)—An old English name given red wines of France generally, and especially to those of Bordeaux; but not to Burgundy wines.

The approximate claret vintage of a favourable year is estimated at about £40,000,000 sterling.

Clarets are divided into several classes, according to their excellence, the chief vine tracts being those of Medoc, Graves, Palus, and Blanche, each particular vineyard producing its peculiar sort of vine; that of Medoc yielding the glorious Château Margaux, Lafite, Latour, and others, such as Leoville, Larose, St. Julien, St. Estephe, Bramme Mouton, etc. The famous Haut Brion is from the vine tract of Le Graves, as also the white wine known as Vine de Grave.

The wines of the flat and fertile Palus are deep-coloured, full-bodied, rough and hard when new, but they improve much by keeping, are well adapted to long voyages, and are known as *Cargo Wines.* The Blanches, or dry wine district, give us Sauterne, Barsac, etc., besides the famous white wine *Château d'Yquem.*

The best clarets are of bright deep ruby or violet colour, exquisite bouquet, approaching the flavour of the raspberry and violet, of soft silky taste, also very refreshing and invigorating, especially in hot weather.

In France, however, the names *clairet* or *vin ordinaire* are applied to any poor, weak, and inferior wines of a light colour, irrespective of district; the red wines of Bordeaux being distinguished either as *Bordeaux*, or by the name of the particular place where the grapes are grown.

Good clarets should contain 5 to 6 per cent. of absolute alcohol; and both these and other wines of the same class should not be decanted until about to be used.

As with Burgundy, clarets seem to be increasing in favour with British consumers, but it is no less a fact that a great deal of the claret now made in France is from inferior Spanish wines.

It may not be generally known that the mode of drinking claret among Bordeaux connoisseurs is to drink from four to seven different marks of claret during dinner, beginning with the lower grades and youngest wines, and with each dish progressing upwards to the higher growths, all of the same vintage. It is considered that in this way, and by the choice of appropriate dishes, the true qualities of the wines are brought out and done justice to, and thus the delicacy, bouquet, and fine qualities of the vintage can be appreciated to the fullest extent.

Clarke's Blood Mixture.—(See also *Patent Medicines.*)—An 8 oz. bottle analysed in 1875 contained—iodide of potassium, 64 grs.; chloric ether, 4 drs.; liquor of potassa, 30 drops; water, 7½ ozs.; and coloured with burnt sugar. The chloric ether here mentioned is made by dissolving 1 part (by volume) of chloroform in 19 parts (by volume) of alcohol.

In 1893 an analysis showed 48 grs. of iodide of potassium to the 8 oz. bottle.

Clary.—(Also called *Wild Clary* or *Meadow Clary.*)—A kind of sage plant, *Salvia sclarea*, native of Southern Europe, grows about 2 feet high, with a clammy stem, large heart-shaped leaves, and pale blue flowers.

It is used for flavouring soups, etc., and in confectionery. A stimulating medical wine is also made from the flowers.

Clayed Sugars.—Those which have undergone a partial clarification, or refining from the molasses and other impurities, by filtering through a thick layer of clay.

The system is now practised chiefly in China, and the sugar so treated is exported from there to foreign countries.

Clayote or **Choco.** — A tree of Mexico and Venezuela. The fruits are edible, and occasionally sold in Covent Garden market.

Cleansing Clay.—A natural earth ground and prepared by Mr. R. J. Ll. Price, at Rhiwlas, Bala, North Wales.

Cleansing Crystals.—See *Washing Powders.*

Cleansing Powders. — PATON'S "CLEANALL" POWDER has the largest sale amongst the principal steamship companies for washing and cleansing paint work.

It is manufactured by PATON, CALVERT & Co., proprietors also of the "Matchless" Metal Polish, Leeds Street, Liverpool.

Another popular make is that of H. May & Co., Ltd., Goodinge Road, Islington, London, N.

Gardner's patent "Rapid" Sifter and Mixer is suitable for any of the above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Clingstone Fruits. — Stone fruits (such as certain varieties of peaches, plums, etc.) in which the stone grows to the pulp adhering to it, and not separating on ripening. *Freestone* fruits, on the other hand, are those varieties in which the stone separates from the pulp, and often rattles about when ripe.

Clock or **Watch Oil.**—Ger. *Uhröl.* (Also called *Porpoise Oil* and *Sewing Machine Oil.*)

A very fine oil obtained from the blubber of the porpoise, and especially from the head, has long been used for the above, so also has finest sperm oil (frozen), almond oil, and the oil of the hazel nut; but the following is the best for the finest horological work:—Take the purest and lightest oil obtainable, and place it in a retort with eight times its weight of absolute alcohol. Boil it for ten minutes, decant the liquid and allow it to cool, then let it evaporate until its volume is reduced to a fifth, filter and keep it in well stoppered and sealed bottles. It also answers well for sewing machines, cycles, etc.

All natural oils contain acid and solid matter, and delicate machinery is often much injured by their use. Oil for clocks should be very pure, and can be made so in this manner:—Put a quarter of a pint of lime-water to a pint of oil in a bottle, shake it well, and let it stand for five days. Then draw the oil off for use.

Clos-Vougeot.—This highly-esteemed burgundy wine takes its name from the village near which the "*clos*" (close or field or vineyard) is situated (Côte d'Or). It formerly belonged to the nuns of Cîteaux.

A large amount of wine is sold as Clos-Vougeot, but the genuine product is very limited.

Cloth Reviver (Black). — Several preparations are sold under this and other names, such as *Shine Remover*, *Anti-Shine*, etc. They are for restoring the colour of faded black cloth, or for matching the shades of same.

One recipe is—4 oz. galls; 1 oz. each of logwood, copperas, and iron filings; and 1 quart of vinegar; mixed by heat, and, when cool, 1 oz. of ox gall is added.

Another recently patented solution consists of a mixture of turpentine, ammonia, methylated spirit, ether, and water.

Clotted Cream.—(See also *Cream.*) —The increasing fancy for this delicacy, and the regular sale that is springing up for it in all large towns, is well worth the notice of grocers and provision dealers. Farmers are paying much more attention to its production now than formerly.

It is commonly made by heating the milk after the cream has risen and allowing it to cool again before removing the thick crust thus formed. A little formalin, boracic acid, or preparation of borax are the usual preservatives, but lime and cane sugar are sometimes used. The preservative is first dissolved in a little milk, and then stirred into the cream, but the three first-named preservatives are now held to be adulterations.

There are, of course, many qualities, but Devonshire seems to bear the palm for its clotted cream. Every one who

has visited the West country, especially Ilfracombe and Devon, will be familiar with it.

The new milk is allowed to stand for some hours undisturbed in the milk bowls or tin pans; these are then placed on a hot-plate or in a copper, and very gradually raised to a temperature of about 180° to 190° F., or until it begins to simmer.

Without disturbance the pans are replaced in the dairy, when the cream gradually thickens, and after about twenty-four hours is skimmed off. It is often sold by weight at same price as butter, and Devonians claim the superiority of their production to be due to the peculiar richness of the milk in the cream district. The cream which rises to the surface is sometimes so thick that it is declared it will hold a flat pound weight on the top without breaking through. It is prepared in much the same way in Cornwall.

Clotted cream contains not only the fatty matters of the milk, but also some of the albuminoids in a coagulated condition; and the delicate flavour seems to be best developed by allowing the cream to rise and ferment by the normal process.

Separators are objected to, as producing weak cream and of inferior flavour.

Town-made clotted creams are usually made from milk that has been jolted about all day along the streets, and finally scalded at night, "to save its life."

Cloudberries.—(See also *Dewberries, Bilberries, Cranberries, Brambles, Mulberries,* etc.)—This northern berry, identified by botanists as *Rubus Chamæmorus*, is very scarce in England; but in the sub-Arctic and Arctic swamps, is very plentiful, and is considered an exquisitely flavoured fruit. It is allowed to surpass Bilberries, Cranberries, and other varieties of wild fruit of this order.

Cloudberries and cream form the last course in every Norwegian sportman's evening meal, and they usually greet him in the early morning with his coffee.

Clove Bark.—(Also known as *Culilawan Bark, Clove Cassia,* or *Clove Cinnamon.*)—It is the bark of the *Cinnamomum culilawan*, a tree of the same genus as the cinnamon tree.

It possesses an aromatic odour like that of nutmegs or cloves, and is often mixed with ordinary cinnamon or cassia bark.

Clove Cordial.—Sold largely in London public-houses. A liqueur of weak spirit flavoured with cloves, sweetened, and coloured with burnt sugar.

Cloves or Clove Buds.—Da. *Nelliker;* Du. *Kruydnagelen* (nail spice); F. *Clous de Girofles;* Ger. *Naglein, Gewürznelken;* It. *Garofani;* Pol. *Gozdrik;* Port. *Cravos;* Rus. *Gwosdika;* Sp. *Clavos;* W. *Ffrwth o'r India.*

Cloves are the dried, unopened, or unexpanded flower buds of the clove tree or evergreen shrub, *Caryophyllus aromaticus*, formerly classed as *Eugenia Caryophylata*, a kind of myrtle, native of the Molucca Islands, but now cultivated in Zanzibar, Penang, West Indies, and other tropical countries, especially Africa, although the Dutch at one time made every effort to limit the production to Amboyna and certain other of the Moluccas, by extirpating the plant elsewhere.

The trees grow 20 to 40 feet high, every portion of which is aromatic. They are very slender and graceful in appearance, commencing to bear in their fifteenth year, and continuing until seventy or eighty. In form it resembles the laurel and sometimes the beech, trunk straight, and rises 4 or 5 feet before it throws out branches. The bark is smooth and thin, and adheres closely to the wood, which is an ugly grey colour and of little use.

The trees are very petted, and do not thrive well near the sea, where they suffer from the spray, nor in the higher mountains, where they suffer from the cold.

There are about half-a-dozen varieties of cloves, viz.:—

(1) The ordinary cultivated clove.

(2) The "female" clove, which has a pale stem.

(3) The "Keri" or "loory" clove.

(4) The Royal clove, which is very scarce; and the Wild cloves of very little flavour or value.

The three first are equally valuable as spices, but the female clove is best for distilling of essential oil.

The dried clove itself is of reddish brown colour, rather over half an inch long, and consists of a dark brown wrinkled calyx tube, surmounted by four teeth which grasp a little ball or knob, thus giving the clove a nail-like appearance; hence its French appellation "*clou*" (nail), and Spanish "*clavos*."

These flower-buds grow in bunches on terminal flower-stalks, very like the flower-buds of the lilac tree. While green, or the stem just turning a pinkish yellow, the buds are, more or less, carefully picked by hand, and then dried a week or so in the shade or cured by hanging them on hurdles by the smoke of slow wood fires—losing about half their weight in the drying process. They are usually finished off in the sun, which gives them a darker colour. In some places they are scalded in hot water, but this is not common. The quicker they are dried the less is the waste of aroma. A properly dried clove is of a light brown or tan colour.

If not picked in time the stem turns red, and the little balls or knobs become unfolded, and burst out into flower during the drying process, and the cloves then become almost valueless as a spice, and are then called *mother cloves;* or, if picked too young and green, the dried cloves will be shrivelled.

Good cloves have a strong aromatic smell and a hot spicy taste; they contain about 20 per cent. of volatile oil, 6 of resin, 13 of gum, 13 of tannin, etc., 28 of woody fibre, and 18 of moisture. They should be uniform in colour, and leave an oily impression on the fingers when handled.

When newly gathered a great portion of the oil is sometimes extracted, and this leaves the cloves pale, thin, and shrivelled in appearance, although they may be afterwards freshened or brightened up a little by rubbing with oil, or passed off by mixing with good cloves. Cloves which have been tampered with in this way will be noticed to have a large proportion of their knobs or heads knocked off.

Another cause of headless cloves is, as already shown, they may have been too far advanced when gathered, that the knobs burst into flower during the drying process; for the clove buds on a bunch are never all ready at the same time. The bunches *should be* gone over very carefully to gather those buds which are fit, but in Zanzibar and Pemba, Arab labourers and Indian coolies being scarce at that busy season, the gathering is usually done hurriedly and roughly.

Cloves are also liable to be adulterated with an excess of stems, sticks, or stalks, which contain very little virtue.

The colour generally desired in cloves is red, and buds of this colour ("red heads") are usually more valued than the black. *Amboyna cloves*, however, which are small and dark brown, are still considered to be the best, and are also distinguished by the title of "Royal cloves," but they are very scarce.

Penang cloves, from the Straits Settlements, have a high reputation, and command a higher price than either Amboyna (Moluccas) or Zanzibar cloves. They are large, plump, and of bright colour. They are picked by boys and girls, and spread on large sieves or mats of loose texture, and merely dried under the shade of trees or in sheds with palm-leaf-covered roofs till ready for market. A strong objection prevails against the *direct* sun-drying process, because it not only shrivels and blackens the buds, but also extracts or evapporates much of their strength.

Zanzibar and *Pemba cloves*, usually dried in the sun on mats are smaller than Amboyna, with the buds or knobs frequently broken, also often mixed with stalk and foreign matter.

About four-fifths of the crop of the whole world is now grown in East Africa, and cultivated chiefly by slave labour. Zanzibar is the great centre of the trade, which, indeed, forms the staple item upon which Zanzibar and Pemba depend.

The production of these two islands averages about 20 million pounds a year, about one-fourth of which are grown in Zanzibar and three-fourths in Pemba.

A ten-year old tree yields about 20lbs. in the year, and a tree of twenty years about 100lbs.

The difference between Zanzibar growths and those of Pemba is very marked. Zanzibar cloves are always of a bright reddish colour, generally very dry, and can be stored a long time; but those of Pemba—small and dark in colour—mostly arrive damp, and are disposed of quickly, as they lose weight if kept; but both kinds, however, often come mixed together.

The proper season for picking, drying, and marketing these cloves extends from September to March, although they continue to be brought into town for some months later, either because some of the trees are retarded in their flowering or because the growers are holding back for a more favourable market.

They only realise on the spot about 10/- per frasila or frazilleh (a Zanzibar weight of 35lbs.). The natives are also apt to adulterate the cloves with salt, but if discovered such goods are now seized and burnt on the spot.

The best cloves are usually imported in chests, and the cheaper in double mat bags or bales of 140lbs., in which latter they will absorb about 8 per cent. more atmospheric moisture in Europe than in Zanzibar. They should average about 4,300 to the lb.

Where quantities are dealt in, it is too often the practice of dishonest merchants to place buckets of water near, so as to increase the weight of the cloves by letting them absorb moisture.

The clove tree was first introduced into Mauritius in 1770 by the French, and at the end of the century an Arab, named Harameli-bin-Saleh, accompanied a French officer from Zanzibar to Bourbon, and obtained permission to take back a small quantity of seeds and plants with him.

This was the commencement of clove cultivation in Zanzibar, Harameli making the first plantations or "shambas" at Mitoni, on the road to Chueni. The different methods by which this cultivation is now carried on are evidently copied from the French; and the Swahili word for clove, *garafu*, is probably a corruption of the French word *giroflier* (clove tree).

The world's annual consumption is about 80,000 bales, and the crops now often exceed that, so prices have become very low. The price which Zanzibar cloves realise is never so high as that for Amboyna and Penang varieties. The latter, being gathered and treated more carefully, are found richer in oil and finer in flavour, although dried by fire.

Clove Stems.—These contain a little oil, and large exports are made from Zanzibar, especially to Bombay and New York.

Cloves, Essence of.—A flavouring for culinary purposes, usually prepared from oil of cloves—say one part of clove oil mixed with eight or twelve parts of rectified spirit. Sometimes one part of magnesia is added.

Cloves, Oil of.—This rich volatile oil is distilled with water from the young unopened flower-buds of the clove tree, or rather the little ball which is seen at the end of the clove, although the oil pervades more or less every part of the tree. The oil, when new, is almost colourless, with a faint yellow tinge, and the strong smell and burning taste of cloves. When old it turns to a reddish brown colour. Its chief value depends on the quantity of *eugenol* it contains.

London is the chief centre for clove oil, but large quantities are made in Amsterdam and Rotterdam.

It is the least volatile of all essential oils, and sinks in water. Often used as a remedy for griping pains and toothache—dose, 1 to 5 drops. It is also used for flavouring liqueurs, confectionery, etc., and for scenting soaps, etc.

Coals.—F. *Charbon;* G. *Kohlen;* Port. *Carbao;* Sp. *Carbon.*

The production of coal in the United Kingdom is greater than that of the rest of Europe combined. Coal consists of carbonised vegetable matter impregnated

in various degrees with the pitchy and resinous substances so characteristic of the fir family.

Peat bogs in superficial beds present, perhaps, the first stage in the change (see *Peat Moss*, etc.), and then the lignite or brown coals of the Tertiary age.

True coal is very compact, has for the most part lost its woody and fibrous character, and contains but a very small quantity of earthy matter.

It consists of two principal varieties, the bituminous and the anthracitic.

Bituminous coals contain an abundance of gas, tar, paraffin, and such like substances, and therefore burn with a brilliant flame.

Anthracite coal is very hard and glossy, not soiling the fingers. It is almost pure carbon, and its vegetable structure is still traceable under the microscope, and it contains very little gaseous matter, therefore burns with very little or no flame, but gives intense heat, and when used in blast furnaces is very effective in iron manufacture, etc.

Cannel or *Parrot coal* is a compact, jet-like variety of bituminous coal and the richest in volatile constituent. In Scotland it is called "Parrot."

Steam coal, so called because of its suitability for vessels taking long voyages, is a semi-bituminous kind, burning with less brilliancy and rapidity but affording great heat.

Bovey coal.—A local name for the lignite, raised near Bovey, or Bovey Tacey, in Devonshire.

Blind coal, or *Smudge coal*, is coal partially deprived of its bitumen, and converted into a sort of natural coke, by the contact of heated masses, such as trap-dykes, etc.

Splint coal is a Scotch term for a variety forming hard laminæ, which, on fracture, split into flaggy layers.

Coal Oil.—See *Naphtha*.

Coal Tar or **Gas Tar.**—See *Tar*.

Coal Tar Soap.—Is generally made by beating together 2 parts of soap shavings, 2 parts of liquor of potassia, and 1 part of tar; or it may be also made by melting together, say, 20lbs. cocoanut oil and 3lbs. of coal-tar, saponifying the mass with 11lbs. of caustic lye of 11° B.

Another is made from 20lbs. cocoanut oil, 10lbs. tallow, 5lbs. juniper tar, and 15lbs. of soda lye of 40° B.

It is considered an excellent disinfectant, also good for eruptions of the skin.

Cobalt Blue.—Da., Du., and Rus. *Kabalt*; F. *Cobalt*; G. *Kobalt*; It., Port., and Sp. *Cobalto*; Sw. *Kobolt*.

A pure colour of high luminosity obtained by grinding very fine a deep blue glass called smalt, which is an oxide of the metallic ore known as cobalt, found in Saxony and Sweden. That from Saxony is the best.

The word Cobalt had a superstitious origin. The German miners used to give the name "Kobold" to a demon who was supposed to inhabit the mines, and, as the ores of cobalt gave them a lot of trouble, they attributed it to the evil doings of the demon, and called the metal after him Kobold, or Cobalt.

Cob-nuts, Kentish Cobs, etc.—A highly esteemed type of the common hazel nut. They are grown rather extensively in Kent, especially about Maidstone, and in other parts of England.

The Kentish cobs are very large, and, the tree being a hardy subject, it is easily propagated, either by suckers, layers, or by budding and grafting. It is not particular as to soil, so that many steep banks and stony patches of land that will not grow better fruits are planted with nut trees, 12 to 15 feet apart, and frequently other vegetable crops or bush fruits are grown between them till the nut trees require all the ground. They are grown about 6 feet high, and pruned so as to form so many inverted umbrellas.

The nuts are almost round in form, hard-shelled, and the leafy laciniated cup, or husk, which holds the nut is smaller, more open and less jagged at its extremity than is the case with other varieties of hazel-nuts. The kind which has red-coloured pelicles round the kernels is considered the best. In Kent they are gathered as soon as the husks and nuts turn brown, and when quite

dry. They are best gathered before they drop out of the husks, although they are often shaken off the trees and then picked up. A good plantation will yield about half a ton to the acre, and in prolific years two tons have been gained. They are afterwards spread out thinly in a fairly dry place, but not so dry as to shrivel up the kernels. Fresh air should be freely admitted so as to prevent mould attacking them.

Prices vary from 25/- to 60/- per 100lbs. Considerable quantities of cob-nuts are also imported from the South of Italy, especially Messina. (See also *Hazel-nuts*, *Filberts*, *Barcelona Nuts*, etc.)

Coca or **Cuca Leaves.** — These leaves are in no way related to *Cocoa nucifera*, the large milky nuts sold by fruiterers, nor to *Cacao theobroma*, the beans from which drinking cocoas and chocolates are manufactured, nor are they in any way connected with the Coco-root plant, *Caladium esculentum;* but are from the bush or vine known, botanically, as *Erythroxylon coca*, growing 2 to 8 feet high, with straight branches and brilliant green leaves, in most of the northern parts of South America, in the valleys of the Eastern slope of the Andes, also in Ceylon, and chiefly in Bolivia and Peru. The old Peruvian name for the fruit is *Cuca*, but the more modern Spanish word is *Coca*.

The main plantations are in the Otuzco, Huamachuco, and Cajabamba provinces. The plant closely resembles the blackthorn, and grows in dry soil generally at about 2,500 feet above sea-level, as a common weed in India. There are nearly a hundred species of the leaf, of more or less medical value; but the two principal are Peruvian or Truxillo, and the Bolivian or Huanuco, of bright, leathery appearance, and with a ridge-like mid-rib.

The best leaves are provided with a minute horny apiculus, which, however, in many samples, is broken off.

A third species, known as *Novo-granatence*, with narrower leaves of pale green colour, said to be very carefully dried, is exported from Java to Holland and Germany. Peru exports more than any other country. The Peruvian leaves are somewhat small, thin, and brittle, of a clear light green colour on both sides, but are not so highly esteemed as the Bolivian, which are usually about three times the size and quite shiny.

Although the richest leaves grow in dry soils, those grown above 4,000 feet are very inferior, both in strength and aroma, as also are those larger plants often grown 10 feet high on the moister soil of Chuquillanqui River. The plants are cultivated entirely for the sake of their leaves, which, when fresh, have remarkably stimulating properties. Like tea, coffee, kola, and maté, coca appears to be a powerful stimulant, its active principles being cocaine, *hygrine*, etc.; while its narcotic properties exceed those of opium, tobacco, or any other plant.

The younger leaves contain twice as much cocaine as the older leaves, and usually possess a pale brownish-green tint with a tea-like odour. Coca leaves are somewhat similar in appearance to those of the myrtle and to tea-leaves, but they never have the dentated margin, and on the under side may be noticed the prominent curved line on each side of the mid-rib, which easily distinguishes them from other leaves.

Coca is chewed by the natives in a similar manner as tobacco in England, opium in Turkey, betel in India, or the kola-nut in Africa, and produces an undeniably sustaining power, a sense of warmth in the mouth, with a pleasant pungent taste.

The fresh leaves are generally chewed with a little powdered unslaked lime, and in Peru the coca chewer takes his three or four portions a day. A sort of tea is also made from the leaves, and cases of intoxication from its use are not uncommon; but they do not anywhere appear to be generally employed in the form of tea or ordinary beverages. (See *Coca Wine*, etc.)

There is a factory in Callao and two in Lima where it is made into *Cocaine;* but the principal depôts are at Huanuco, Ayacucho, and Cuzco in the interior. The leaves are also prepared in small

balls, called "Acuclicos," ready for mastication.

Although it is only since 1874, when it was first brought into prominent notice in England, that our scientific men have interested themselves in its medicinal properties, the coca plant has been known ever since the conquest of Peru, and there is no doubt of its efficacy in temporarily soothing the nerves, driving away sleepiness, and greatly preventing the short-windedness and fatigue often felt in forced marches, running, climbing staircases, etc., hence it may be of considerable value to athletes and others.

Experiments by Lombard show that coca, coffee, tea, guarana, and maté, all have considerable influence in increasing the power of the organism to resist muscular fatigue. Coca takes first rank, and especially stimulates the muscular energy, maintains its action for a longer period, and its use is not followed so soon by either nervous or muscular exhaustion. The others rank in the order named. Infusions of coffee, tea, and maté possess a tonic rather than a stimulant action on muscular energy, and this tonic effect of coffee is apparent for about an hour after its ingestion; while the effect of tea, maté, and guarana lasts for half-an-hour only. Not only does coca impart vigour to the muscles and intellect, but a temporary feeling of exhilaration to the whole system. It has also been found an excellent specific for asthma, and for the cravings of the victims of opium and morphine, but, unfortunately, similar effects result from its abuse or continual use—weakness and nervous exhaustion.

The leaves should be dried as quickly as possible in the shade (not in the open sun), and used as early as practicable afterwards. It is, in fact, very doubtful whether the old dried leaves conserve the goodness of the fresh green leaves or any virtue at all, especially if they have fermented through being packed insufficiently dried.

The prices of coca leaves in the London market vary from 3d. to 6d. per lb.

Coca Wine.—The sustaining and powerful properties of *Erythroxylon Coca* has been so much written about that we now have it in various forms. American and Paris druggists send it as coca tea, lozenges, liqueur, extracts, pastilles, and wine. The latter is now commonly a solution of the alkaloid cocaine, in a sweet and usually strongly alcoholic wine.

It is also prepared by mixing the fluid extract of coca leaves with wine, say, 3 parts of extract with 24 parts of Malaga wine. When thus mixed it may be allowed to stand 12 hours, then poured off, and filtered bright through pumice-stone. Uniformity of strength is not so easily ensured.

Some coca wines only contain about 0·01 per cent. of cocaine. If the wine contain too much, it tastes very nauseous, and a wineglassful of it produces a very unpleasant sensation in the mouth and throat.

A considerable quantity of coca wine was recently ordered by General Duchesne for the use of the French troops proceeding to Madagascar, although the use of it to relieve nerve fatigue is attended with considerable danger, and is likely to lead to a pernicious abuse of the drug with disastrous results. Indeed, the continued use of cocaine is very injurious. It is even stronger and worse than *Calisaya*, and persons who once give way to either can seldom give them up. The possibility of risk is intensified by the varying strengths of the coca wines on the market, some containing as much as half a grain to the ounce and others as little as one-hundredth of a grain.

Two liquid extracts of coca are usually sold by druggists. One prepared by maceration and percolation of the powdered leaf with proof spirit, but in this so much chlorophyll is carried into solution that when mixed in water or wine of low alcoholic strength it turns the mixture turbid and unsightly, so that the public do not care for it. The other miscible preparation is more elegant. It is prepared by repercolation with a mixture of one part of rectified spirit with 2½ or 3 parts of water and with

or without an addition of glycerine. This forms a quite clear mixture with, say, orange or ginger wine.

Coca Wines, professedly consisting of the coca alkaloid and wine, for use as medicines, and, unless sold by licensed holders, are required by the Excise to contain half a grain at least of the alkaloid in each fluid ounce, so as to ensure their being unpalatable and unsaleable as beverages.

Cocaine. — A poisonous vegetable alkaloid (*Cocaine hydrochlor*), discovered in 1859, and obtained from *Coca* leaves. Solutions of it can only be sold by legally qualified chemists, and every sale must be entered in the poison register.

In this country cocaine is generally prepared by purifying the crude cocaine manufactured in Lima. The Bolivian pale brown leathery leaves yield the best quality, and the leaves of the young plant yield over double the quantity of alkaloid found in the older shrubs.

Java leaves go mostly to Germany, and yield but little cocaine.

The province of Otuzco, in Northern Peru, is the most important district of coca cultivation. It produces over 200 tons of the leaf yearly. The crop is received from the haciendas by two houses in Truxillo, which dispose of it to the cocaine manufacturers in Lima.

About 2,000 kilos of crude cocaine are exported yearly from Callao.

Cochineal. —Da. *Conchenilje;* Du. *Konzenilje;* F. *Cochenille;* Ger. *Koschenille;* It. *Cocciniglia;* Per. *Kernij;* Port. *Cochenilha;* Rus. *Koshenille, Koussenel;* Sp. *Cochinilla;* Sw. *Kochenil;* W. *Lliw coch.*

A colouring extract or beautiful red dye for scarlet and crimson, prepared from the scale insects known as *Coccus cacti*, which belong to the *Hemiptera* or half-winged order, and, although native of Mexico, have been cultivated or propagated over fifty years in the Canary Islands, in what are called "nopaleries," and exported to all parts of the world. Some come from Teneriffe and Algeria. Inferior and wild kinds also come from Mexico, Honduras, and Guatemala, which produce only a ruby colour; but in the Canary Islands the commercial importance of the cochineal industry is only second to that of the vine. They thrive best on the "nopal" or *Cactus opuntia* (Indian fig-tree).

There are three varieties, viz., black grain (*Grana fina*), gathered in March, and used for carmine; silver grain (*Grana sylvestra*), very rich in the waxy coating so characteristic of the grey cochineal. The "rosy-black grain" is made up of either of the others, when killed by a wet process, whereby the waxy coating is melted, and varnishes the body of the insect. The two former kinds are killed by suffocation with either charcoal or sulphur in the sun.

The insect itself is about the size of a pea—about 70,000 go to the pound; but the females, which are wingless, are much larger than the males, and by far the most numerous. The body is almost shapeless, sometimes oval and sometimes globular. It has a silvery grey appearance, the body being of a reddish black or mulberry colour, covered with fine white dust; and it is remarkable the insect itself for several centuries used to be considered a kind of vegetable grain or seed, hence their name of "grain."

The legs are very imperfectly developed, and make them look like shrivelled berries.

Locomotion is impossible to them, and they live motionless, sucking the juice out of the cactus leaves, by means of a pointed beak with which they are provided.

They are gathered three or four times a year, as soon as the females have finished laying their eggs, being scraped from the plants on which they feed by a blunt knife, filled into bags, and are then dipped in boiling water to kill them; after which they are dried in the sun and exported—the white coloured and heavier in bags of about 200 lbs. weight, the black and the grey (which are lighter) in bags of 140 to 160 lbs.

The introduction of the aniline dyes—especially the sudden impulse given to them in 1879—has reduced the value of cochineal very considerably; still it is

said to be the only red dye which satisfactorily resists hard wear and heavy rains.

The dye is obtained by first fixing the colouring matter of the insect by a mordant of alumina and ovide of tin, and then exalting the colour by the action of super-tartrate of potash.

Black cochineal is often heavily loaded with the black sand from the cochineal fields, but is easily detected by means of a magnet.

The best cochineal are the large, plump, and dry *nopal*, or coccus cacti, with a silver white colour on the surface. The cochineal of the fig trees of the East Indies, which is collected twice a year, produces carmine lake; and the cochineal of Poland, which grows upon the root of *Sceleranthus perennis*, gives a good colour. This kind used to be the object of an important trade before the importation of the Canary cochineal, and is still used in Poland and Russia for dyeing morocco, cloth, silk, and hair; but the only sorts now met with in our markets are those from the Canaries, the Mexican from Vera Cruz, and the East Indian from Java, which are inferior, and mostly come in reddish grains, packed in tin boxes of about 1 cwt. each.

Apply to Charles Cocks & Co., Reading.

Cochineal Liquid or Carminic Acid.—Liquid cochineal for culinary purposes, such as jellies and confectionery, is usually prepared by boiling, say, one part of cochineal and one part of salt of tartar in eight parts of water, adding one part each of alum and cream of tartar. When dissolved, strain and bottle.

Or take 1 oz. silver grain cochineal, 1 oz. subcarbonate of potash, 1 oz. potash alum, ½ oz. citric acid, 4 ozs. sugar, and sufficient water. Then bruise and boil the cochineal in a glass or copper vessel of suitable capacity, in 8 oz. of water, to which the subcarb. potash has been added. Mix loosely the alum and citric acid in powder, and add gradually to the boiling liquid, and continue to boil until effervescence has entirely ceased.

While still hot, filter on to the sugar, and wash the filter with hot water sufficient to make the whole measure 12 ozs.

Cockie-Leekie.—A popular Scotch soup composed of fowls—properly, *old roosters*—boiled with *leeks*, and seasoned with pepper and salt. Most used in winter season.

Cockles.—Da. *Musling;* Du. *Kammossel;* F. *Coques;* G. *Musseln;* It. *Bonchiglia;* Pol. *Bribigao;* Rus. *Ghrebeonka;* Port. and Sp. *Almejas;* Sw. *Mussla;* W. *Cocus, Gwichiaid.* (See also *Mussels, Whelks, etc.*)

These small shellfish (*Cardiumedule*) are usually sold by measure; a peck of cockles contains about 1,000.

They are sold either raw or cooked, and their consumption is chiefly confined to the poor.

Usually cooked in their own liquor, or in salt water, and vinegar added, and eaten as "hot cockles."

Cockroach Poison. — See *Beetle Powders.*

Cocks' Combs.—Dressed and preserved, and usually put up in bottles. These are the fleshy crests or caruncles growing in several forms on the heads of domestic fowls, and particularly developed in the male birds.

The wattles of the hen are also dressed and used in the same way.

Cocks' Kidneys.—See *Rognons de Coq.*

Coco.—A French or Turkish name for a popular drink sold in the Paris streets, and made by macerating liquorice and a little coriander-seed in water. A kind of coco is also sold in the form of a paste, packed in tin boxes. This variety is described as a mixture of extract of liquorice with Vichy salts, to which essential oils of lemon, orange, anise, and peppermint, as well as absinthe and oil of cherry-kernels have been added. The compound is easily soluble in water, to which it imparts a red-brown colour. The presence of the carbonate (Vichy salts) causes an alkaline reaction, which assists the solution of the glycyrrhizin. In this form coco is recom-

mended as a cheap, agreeable, and thirst-quenching beverage.

Cocoa, Raw.—Da., Rus., and Sw. *Kakao;* F., Ger., Port., and Sp. *Cacao.*

The different products passing under this and similar names are referred to under *Coca* and *Cocos*, and it is proposed here to treat of the leading varieties of the raw cocoa from which chocolates and drinking cocoas are manufactured.

Many authorities insist that this product should be called *cacao*, and not *cocoa;* but the latter name has now been generally adopted, and so long used, that in every town throughout England cocoa and cocoa-rooms are household words, and will doubtless remain so.

There are people, however, and even some grocers, who have the idea that chocolates and drinking cocoas are, in some way, made from the large milky cocoa, or *coker* nuts sold by the fruiterers. Such, of course, is not the case. The nuts or beans furnishing these popular sweetmeats and beverages are the berries or seeds of the *Theobroma cacao*, from the Greek words *Theos* (god) and *Broma* (food), or "food of the Gods," a title conferred upon the product by Linnæus. The tree is a tropical evergreen of stunted growth. It is somewhat angular without any main stem, but usually sends up five or six stalks from the ground, which grow 12 to 30 feet high. It is a native of either Central America or the West Indies, but is now cultivated in most of the tropical countries, especially in Ecuador, Venezuela, and the West Indies; by the English in Trinidad, Grenada, and Ceylon, the French in Martinique and Guadaloupe, the Spanish in Cuba and the Philippines, and the Dutch in East Indies, Java, etc.

As with orange trees, there are at least a dozen species of the cocoa or chocolate tree, and the produce varies almost as much in quality and taste. The cocoa trees are in appearance, however, all very much alike; the wood is white, vitreous, and light; the spreading branches are topped by drooping dark-green leaves, alternately oval and pointed, and from 8 to 18 inches long by 3 wide.

The blossom bursts forth in clusters direct from the main branches and trunk of the tree, and not from the smaller ends of the branches. Each flower is comparatively small, and consists of five yellowish white petals on a rose-coloured calyx. This is succeeded by a "mazorca," "cabosse," or fruit pod, which, when fully grown, may be 7 to 10 inches long and 3 to 4 broad, resembling a melon in shape, only a little more pointed. The trees require pruning much as vines do, the undergrowth must be kept down, and all outward suckers trimmed, so that the whole strength may be preserved for the formation of pods.

The cocoa tree also, like that of the orange, bears flowers and fruit all the year round; a tree in its prime produces 50 to 100 pods a year. The colour of the pods varies, according to the season, from bright yellow to red and purple. The branches are not grown low, so that in looking along a plantation the vista has been likened to a miniature forest hung with thousands of golden lamps—anything more lovely can scarcely be imagined.

The two main harvestings are about the end of May and the end of October, when the riper pods are gathered, and afterwards chopped open. Each pod is found to contain 20 to 30 beans or seeds, arranged in five regular rows round a common centre, and embedded in a pinky white-coloured spongy substance like that of the melon.

Some growths of cocoa are very strong flavoured, others are remarkably mild flavoured. They have been classified as follows, and named according to their degree of strength or mildness of flavour.

Strong Flavoured.	Mild Flavoured.
Africans	Ceylon
Surinams	Java
Cayenne	Puerto Cabello
Demerara	Caracas
Bahias	Fine Summer Arriba (Guayaquil)
St. Thomé	Colombian & Cauca
Trinidads	Carupano
Grenadas

Tobago	Mauritius
Dominica	Seychelles
St. Domingo { Jeremie	Madagascar
St. Domingo { Samana	Tumaco
St. Domingo { Sanchez	Esmeraldas
Cuba	Madras
Para	Neilgherri
	Jamaica

These beans, nuts, seeds, or berries—they get all these names—somewhat resemble almonds, and (when separated from the pod) are conveyed to the "sweating house," where in boxes or barrels they are submitted to a process of fermentation for four to ten days. This softens the bitterness, clears them from all impurities adhering to them, prevents sprouting, and gives them when cured that rich mahogany tint and consistence so much sought after by our best cocoa manufacturers. While fermenting they are regularly stirred every morning, and carbonic acid with a strong vinous liquid is given out. The fermentation ceases the moment the beans shed the pulp by which they are covered.

This fermenting or sweating is a very important process, because on its success depends the after value of the cocoa in the European markets. It disperses the rather unpleasant bitter and oily taste natural to the raw bean, and develops an aromatic flavour and smell. In Mexico and elsewhere the same object is attained by burying the beans in pits in the earth, but this system is not considered so good as the first-named.

After fermentation the beans are finally sun-dried and rubbed by hand; but while being exposed to the sun, and turned over with a paddle in the open air, they must be carefully watched, and run under cover in case of too much sun or of sudden rains and dews. If neglected, excess of heat parches and shrivels them; or if wet they will take an ashy colour, have a disagreeable taste, and thus lose half their commercial value.

When perfectly dried they emit a cracking sound, and if well cured the outer skin is hard and crisp, separating easily from the inner bean. The latter should be firm and bright, breaking easily on pressure into the familiar form of cocoa (or cacao) nibs. The dried beans, when stored in quantity, should be kept away from spices or other strong smelling goods, in perfectly dry and well-ventilated rooms, and require to be turned over frequently, or they will rot.

They are usually shipped to Europe in bags or skins of about 1 cwt. each, and it is in this form that the raw article reaches the English cocoa and chocolate manufactories.

One man can take care of a thousand trees, his chief trouble being the sudden changes in the weather—a heavy shower of rain will often cause many of the pods to fall off the trees. The ravages of animals (monkeys, deer, and parrots) also require constant vigilance. In the Seychelles, the cocoa harvest has more than once proved a failure on account of the rats eating through the fruit to get at the seeds as soon as it ripened.

As already stated, the cocoa tree is cultivated in most of the hotter climates, but the Ceylon product now brings the highest prices. It has risen in favour very much these last 20 years, and possesses the most delicate flavour, aroma, and colour. The best has surpassed even the celebrated Trinidad and Caracas growths. In 1878 Ceylon exported only about half a ton of cocoa, but now (1900) she exports over 2,000 tons a year. The plant, however, requires rich sheltered land, and there is only a limited area in Ceylon where it can be successfully grown.

Trinidad cocoa still ranks very high in price and quality. In that island the cultivated cocoas form the second great staple, and are divided into two classes, *Cacao Criollo* (yellow cocoa) and *Cacao forastero* (purple or foreign). There are some 97,000 acres of land devoted to cocoa growing, and the annual crop is from 20 to 25 million pounds. This cultivation has been established from the earliest days of the colony. Forty years ago there were only 7,000 acres planted with cocoa. There still remain over 700,000 acres of land in possession of the Crown, nearly 300,000 of which consists

of some of the finest virgin soil of the island. To young men with capital, steadiness, and, above all, perseverance, who may be looking for some profitable means of investing capital, we unhesitatingly say, "Try Trinidad." The town of Arima may be considered the centre. The trees require shading from the burning sun, and this is managed by planting two species of *Erythrina* among the cocoa trees.

The young cocoa plant has no insect pests, but has two deadly enemies, the foremost being a grub larva of the beetle *Stirostoma depressum*, which eats its way in a corkscrew fashion under the bark, and eventually destroys the tree. The second is a bird which provides for its coming needs by making the cacao pod its future larder. It picks a hole in the pod, and soon after follows a family of the above grubs, when, as soon as these are established, the bird descends, and devours its meal, but the pod is spoilt.

Two estates, Soconusco and San Antonio, in the Santa Cruz valley yield very superior qualities—the raw nuts in the London markets generally realising the highest prices, while ordinary growths from several other countries only fetch about half these prices.

Caracas Cocoa, from the Federal district of that name, at the North of Venezuela, also occupies a high position, but from some cause or other its value has been declining these last dozen years. (See separate account.)

Grenada and Bahia also furnish excellent sorts, commanding high figures. In the island of Grenada cocoa has become the main export.

Several good sorts, including one of the most marketable, belong to British Honduras, but the export only amounts to about £60,000 a year.

The other cocoa producing centres are Southern Mexico, most of the States of Central America, Peru, Dutch Guiana, West Indies, East Indies, and the Philippines. Considerable quantities are also grown in Madagascar, Mauritius, and Reunion. The cocoa tree is also now being successfully cultivated in the German Cameroons.

In Central America there is a purely white-seeded species, called *Cacao meco*, or *Cacao mono* (monkey cocoa), producing large pods and splendid beans, which require only 48 hours' fermentation, instead of four to ten days as with other sorts. Another variety, *Theobroma bicolor*, known in Nicaragua as "Alligator cacao," is peculiar from the soft covering of its pod, and the *raised* instead of *indented* sectional ribs.

In Ecuador, whence come the noted Guayaquil growths, the cultivation of cocoa is rapidly increasing, especially in the low-lying districts near the rivers.

The export already exceeds 15,000 tons a year, and comprises some 11,000 tons Arriba, 2,000 tons Machala, and 2,500 tons Balao.

The *Arriba* is grown on the Guayas River and its tributaries above Guayaquil. This is the best grade, and represents about 65 per cent. of the whole crop, the main season for which extends from January to July.

The *Balao*, or second grade, is grown below Guayaquil, in a district adjacent to Port Balao, and equals about 10 per cent. of the whole crop. Season, July to December.

The *Machala*, or third grade, is grown still further south, near the port of that name, and equals about 15 per cent. of the whole crop. Season, also July to December.

There are also "gleanings" gathered and marketed outside the above seasons, and these are called Rebuzcos.

The cocoa district embraces a radius of about 80 miles, with the city of Guayaquil as its base, and now yields about 34 million pounds of cocoa yearly.

Caraquez is another grade, grown in the province of the port Bahia de Caraquez, on the coast north of Guayaquil; and another very superior class, but insignificant in quantity, is grown near the port of Esmeraldas, on the coast north of Bahia de Caraquez.

Of all cocoas Guayaquils give the most trouble to distinguish one quality from another. This difference in the quality is due to the locality of the estate and the season of the year at which the cocoa

is picked; and as localities run one into the other and seasons vary, so do the qualities of the produce, some Caraquez Guayaquil being very difficult to distinguish from some Arribas.

The system of planting preferred there is from seed, and not from shoots or cuttings as is done elsewhere. The cocoa bean is taken fresh from the pod with the pulp, and set at 9 feet distance between each plant, preferably under the shade of a plantain, until the plants are well grown. The enormous number of birds from the surrounding tropical forests are the chief trouble, often causing great havoc to the cocoa crops.

The best way of curing is by a moderate fermentation. Some is washed and partly fermented, but this washing and drying process seems to leave a moisture, which is afterwards thrown out on the surface of the shell, giving it a grey and mouldy appearance. Cocoa fully, but not over, fermented has a bright red colour, and the best samples have a bloom like the bloom of plums on them, which has dried on the shell. It probably arises from a secondary fermentation and the richness of pulp.

The most valuable constituents of cocoa are, of course, theobromine and caffeine, for it really possesses both these alkaloids. Professor Emmenger, a noted German chemist, lately published in the *Apotheker Zeitung* special analyses of the leading growths of cocoa, showing the percentages of theobromine and caffeine found in each:—

	Theobromine	Caffeine.
Puerto Cabello ...	1.05	0.16
Maracaibo	1.84	0.15
Cauca	2.03	0.36
Caracas	1.43	0.07
Ceylon	2.06	0.30
Java	2.34	0.05
Trinidad	1.98	0.09
Para	1.08	0.20
Granada	1.90	0.20
Surinam	1,83	0.20
Guayaquil, ariba ...	1.20	0.20
Cameroons	1.83	0.12
St. Thomé	2.09	0.12
Bahia	2.04	0.16
Samana	1.82	0.16
Cap. Haiti	2.07	0.16
Domingo	1.98	0.16

The cultivation of cocoa is now succeeding in Samoa. The climate is found to produce robust, hardy, and luxuriant trees, which yield abundant crops with but trifling cultivation. The kinds chiefly in favour are the Caracas and *Forastero* variety and a new hybrid, partaking of the best qualities of the two.

"Hardness of break," "flintiness," "soapiness," "grey colour," etc., seen in beans all betoken insufficiency of ripeness and curing; the nearer the bean is to the even-coloured "red" peculiar to its growth, the better prepared and the riper will it prove to be.

The principal sales of raw cocoa take place at the Commercial Sale Rooms, Mincing Lane, London, on Tuesdays.

Cocoa, Manufactured—The growth, harvesting, curing, and shipment of cocoa having been fully described under "Cocoa (Raw)," we may here proceed to refer to the various ways in which manufacturers deal with the beans upon their arrival in this country.

These *beans*—also often called *seeds*, *nuts*, or *berries*—are, after the duty (1d. per lb.) has been paid, first roasted, then broken up into small fragments, put through a winnowing machine, and thus separated into (1) *Cocoa Nibs* and (2) *Cocoa Shells*, or husks. The beans lose weight to about 15 per cent. in roasting.

The *nibs*—rich, glossy pieces of kernel—are, of course, the most valuable, and are capable of yielding a thin, rich liquor of genuine cocoa; in fact, this was the popular form in which cocoa was used in England a century ago; but the time and trouble required to cook it being more than most people can afford, and the beverage itself being too rich and unpalatable for most people, the demand

in retail shops for cocoa nibs was never very extensive, and has long been diminishing.

It is only since manufacturers like Cadbury, Epps, and Fry, by scientific skill and elaborate machinery, have succeeded in producing cocoas ready for immediate use without boiling, that the public at large have taken to them.

For several years the consumption of cocoa has been increasing enormously, while the use of coffee has been steadily declining. The annual consumption of cocoa in this country was :—

In	1830	about	500,000lbs.
,,	1858	,,	2,860,034 ,,
,,	1864	,,	3,862,273 ,,
,,	1880	,,	10,566,159 ,,
,,	1890	,,	20,224,175 ,,
,,	1899	,,	34,013,812 ,,

These figures only show the weight of *raw* cocoa passed through H.M. Customs, but the annual output of the manufactured cocoa powders and chocolates must be considerably more.

There are also some 5,000,000lbs. of manufactured cocoa powders (mostly Dutch) sent to this country, but the sale of these has fallen off remarkably, while the British makes have steadily increased.

Manufactured cocoas of the present day may be conveniently divided into two types, namely, *Thick Cocoas* and *Thin Cocoas;* that is, according to the thick or thin beverages they yield when the powder is stirred in boiling water, and thus made ready for use with or without boiling afterwards.

THICK COCOAS comprise *Prepared Cocoas, Homœopathic Cocoas, Caracas Cocoas, Pearl Cocoas, Soluble Cocoas, Chocolate Powders, Maravilla, etc.,* and in manufacturing them the plan generally adopted is similar to that invented in 1810 by the late Mr. Daniel Dunn, of Pentonville, although other improvements have from time to time been since introduced.

The nibs already described are, by the aid of steam, while grinding them between granite stones, reduced to a semi-liquid state. Sugar and arrowroot, or other farina are then added, and the whole thoroughly mixed in a steam jacketed pan or mixing machine called the "Mélangeur," and not unlike a mortar mill. When sufficiently mixed the soft paste is turned out of the mixer and allowed to cool, and after grinding through a mill or steel rollers it is finally sifted to the desired fineness of the powder required.

Cocoa nibs containing about 50 per cent. of fat, and being therefore too rich for most constitutions, the sugar, arrowroot, etc., are added chiefly for the purpose of making the beverage more generally acceptable to ordinary tastes and digestions. Less milk is needed, and they help to prevent the insoluble particles of the cocoa from settling to the bottom of the cup—for be it noted that cocoa is never wholly soluble—and being cheaper than cocoa nibs they enable the manufactured article to be sold at a lower rate.

Of course all these "Thick Cocoas" vary in quality and price according to (1) the proportion of cocoa nibs employed; (2) the quality of the nibs, and the quality of the sugar, arrowroot, or other farina; (3) the skill employed in selecting the most suitable varieties of nibs, and adjusting the proportions of the several ingredients; (4) the care taken in picking out and rejecting all light, damaged, and inferior pieces of nib.

Some of the leading English manufacturers spare no pains or expense to produce the very best possible article, and rely upon the discernment of the public for lasting patronage. Other manufacturers make little effort beyond substituting inferior materials, and imi-

tating as closely as possible the titles, labels, style of packing, &c., of the more renowned firms.

In many instances the amount of low class beet-root sugar, damaged sago and flour, potato flour, with artificial colouring and flavouring matter, is so considerable, and the amount of cocoa nibs so small and of such coarse, poor quality that the nutritive value of actual cocoa in a cupful must be infinitesimal. Even Venetian red, chicory, cocoa husk, brick-dust, umber, oxide of iron, and other abominations have been found in some of them.

Many of these sophistications, if not palpable to the taste, may be detected by a microscope if they be of vegetable origin, or if of a mineral character by chemical reaction. If kept for any length of time—and they often are—a very nauseous smell is developed, and an earthy or putrid taste, the result being disgust to the consumer, irreparable loss of reputation to the retailer, if not also a loss of cash paid for the rubbishy compound.

It is much to be regretted that in most of the "Cocoa Rooms" these lower qualities of cocoa only are served, thus creating a permanent aversion to cocoa in many persons who naturally expect to obtain it in perfection at those establishments.

Retailers, especially new beginners, should beware of having such goods "specially prepared" for them, and packed with their *own names on*. There are always manufacturers who unable to sell under their own label are ready to imitate the labels, style and colour of paper used by the best-known firms, but these deceptions have always failed more or less ignominiously. The grocer may for a short time feel proud to see his own name on the imitation, but the public know what it all means, and the result usually is more notoriety than popularity.

Indeed, looking back through 40 years we know of no case where *imitations* have succeeded either in cocoas or any other commodities.

THIN COCOAS.—These include Cocoa Essences, Cocoa Extracts, Concentrated Cocoas, &c., manufactured by abstraction, and are of more recent introduction.

They come from pure cocoa, without any addition of sugar, arrowroot, or other farina. Messrs. Cadbury Brothers, of Birmingham, were among the first to make this kind. Several other manufactures have since followed suit, but Cadbury's is probably the best known, and indeed its sale seems to increase at a much faster rate than that of any other make.

In manufacturing these *Thin Cocoas* each firm has, of course, its own particular process, but generally about two-thirds of the natural fat or butter is abstracted either by the aid of fine canvas bags and a powerful hydraulic pressure, which squeezes the excess of fat out of the nibs while in a liquid state, and leaves the remainder of the cocoa a dry powder, or the melted cocoa may be allowed to stand a few hours and cool, when the fat or butter, which will then have risen to the surface, may be easily removed. (See *Cacao Butter*.)

Some say that the abstraction of its fatty constituent from Cocoa is tantamount to adulteration. However this may be, the surplus fat being removed, the remaining portion of the cocoa is afterwards reduced to an impalpable powder, and is then ready for packing either in canisters or cardboard packets.

A teaspoonful of this powder put into a breakfast cup and filled up with boiling water or milk and water produces a dark thin tea-like beverage, which is very refreshing and enjoyable to some who cannot so well digest the thicker manufactured cocoas already referred to.

As with *Thick Cocoas*, there are various qualities of these Essences, Extracts, Concentrated Cocoas, &c.

Sharp competition among manufacturers has tempted some of them to use the very lowest priced or damaged raw

cocoas, but their productions, although *pure* in a sense, are really very inferior, and have no permanent sale.

When it is remembered that the market prices of raw cocoas range from 35s. to 100s. per cwt. it is obvious there must be a wide difference in qualities, although all may be "pure," or without addition.

Many of the lower qualities of cocoa powders are, however, chemically coloured or dyed a dark colour, so as to make them *go farther*, also perfumed so as to hide or disguise the rank and disagreeable flavour of the inferior growths of cocoa used in their manufacture.

In two or three Dutch manufactures the true colour and the natural flavour of cocoa are quite lacking, a false colour and flavour being substituted by artificial means, which give the beverage a blue-black appearance and a sort of "cattle-food smell," both of which are entirely foreign to natural cocoa. This result is attributed to the addition of 2 to 4 per cent. of soda, potash, magnesia, or ammonia during manufacture, which not only deepens the colour, but also, on the addition of boiling water, saponifies the natural fat remaining in the cocoa, thus forming a sort of emulsion which for a short time holds the insoluble matter in suspension, and gives a fictitious appearance of strength.

The percentages of alkali and perfume thus subtly employed are, however, so small that no prosecutions for adulteration have, so far, been instituted in this country for stopping their sale, although Dr. Sidney Ringer, perhaps the greatest English authority on the action of drugs, states that the continued "administration of alkalies and their carbonates renders the blood poorer in solid and in red corpuscles, and impairs the nutrition of the body." Of ammonia, carbonate of ammonia, and spirits of ammonia, he also says: "These preparations have many properties in common with the alkaline potash and soda group. They possess a strong alkaline reaction, are freely soluble in water, have a high diffusion power, and dissolve the animal textures."

The sale of these Dutch cocoas seems to be falling off in England, whether owing to the "slimness" of the drugging and colouring or to the "slimness" the Dutch have shown in South Africa we cannot say, but perhaps both.

The leading English cocoa manufacturers have, however, far surpassed all foreign competitors, and send out their productions without either artificial colouring or perfume.

The beautiful rich mahogany colour natural to cocoa of good quality, and its exquisite aroma—delicate, but distinct—once recognised by the intelligent cocoa drinker, are not often forgotten. (See *Epps's Cocoa.*)

A confirmation of this is shown by the remarkable fact that during the last few years it has been only the higher classes of cocoas, thick or thin, that have increased in consumption. In regard to many other commodities—tea and coffee, for example—the lower and cheaper sorts seem to be prevailing; but with cocoa the contrary is the case.

Most of the cheap cocoa mixtures popular a few years ago have gone to the wall, and the makers have either failed, given up business, or turned their attention to superior productions.

Others there are from time to time trying to introduce trashy low-priced grades, but their efforts appear to be short-lived; and it is only the superior and higher-priced cocoas that seem destined to enjoy public favour in the future.

Gardner's patent "Rapid" Sifter and Mixer, freely used for cocoas. Prices from 50s. to £100. Catalogues from Wm. Gardner and Sons, Engineers, Gloucester.

See also *Homœopathic Cocoa, Pearl Cocoa, Rock Cocoa, Soluble Cocoa.*

Manufacturers and Merchants.—Cadbury Brothers, Bournville, near Birmingham; Compagnie Francaise, Lon-

don Works, Bermondsey New Road, London, S.E.; J. Epps and Co., Ltd., Holland Street, Blackfriars, London; J. S. Fry and Sons, Union Street, Bristol; Hedley, Gamble, and Crosfield, Circus Street, Liverpool; Morris and Jones, 13, 15, and 17 Sir Thomas Street, Liverpool; Clark, Nickolls, and Coombs, Ltd., London, makers of cocoa, pure and simple, put up in packets at 1d., 3d., and 4½d. each, and in tins ¼lb. at 6½d., ½lb. at 1s. ½d., and 1lb. at 2s. 1d.

Cocoa Butter.—There are two distinct kinds. (See *Cacao Butter* and *Cocoanut Oil.*)

Cocoa Essences, Extracts, etc.—See *Cocoas* (*Manufactured.*)

Cocoa or **Cacao Nibs.**—These are obtained by roasting the beans (sometimes called seeds, berries, or nuts) of *Theobroma cacao*, from which drinking cocoas are made. They are roasted in the same way as coffee berries; and when the aroma is sufficiently developed they are passed through a "kibbling" mill, which crushes or smashes them into small irregular pieces, liberating the nib or kernel from the husky covering or shells, which latter are afterwards blown off in a winnowing machine. (See *Cocoa Shells.*)

Cocoa nibs vary in quality and value as much or more than coffee berries, and should always be used fresh. The weight lost in roasting and winnowing varies from 15 to 25 per cent.

The best nibs contain in every hundred parts, 50 of cocao butter, 20 albuminoids, 13 of starch, sugar, etc., 4 of salts, 2 of theobromine, and 11 of other substances.

The trouble and time required in preparing a palatable beverage from the crude nibs, and so as to retain that invaluable alkaloid known as *Theobromine* (a homologue of theine, but far more powerful in its physiological action), is greater than most people can well afford, and it must be admitted that the most successful attempts fall far short of producing the delicate breakfast beverages obtained from the skilfully prepared cocoas of firms like Epps's and one or two others, who have made a life-long study of the business.

The best way of preparing Cocoa Nibs is first to bruise them, then tie them loosely in a piece of thin muslin, put them into cold water, and let them simmer for three or four hours. The liquor must stand till quite cold, when the oil may be skimmed off, which will render the flavour much more agreeable; when required for use, boil it up again, add milk and sugar to suit the palate. (A quarter-of-a-pound of nibs is sufficient for three pints of water.)

No other warm drink approaches cocoa in its nutritive character, because while performing to a certain extent the exhilarating work of tea or coffee, it presents to the human system a very considerable quantity of nitrogenous and carbonaceous matter. This advantage is partly due to the fact that cocoa is taken in the form of an emulsion, instead of an infusion or decoction.

Cocoa or **Koker Nut Oil.**—(See also *Cacao Butter.*) This product is also known as Copra Oil and Cocoa-nut Butter.

It is a rich but coarse granular white oil, of buttery consistence, mostly imported from Ceylon, India, Java, and the Pacific Islands, where it is extracted (either by decoction or compression) from the albumen or ripe kernel of the large, brown, rough, and thick-shelled milky cocoa (or coker) nut, *Cocos nucifera*, usually sold in our fruit shops (but is of quite different origin to the cacao butter obtained from the seeds or nibs of *Theobroma cacao*, which yield the ordinary drinking cocoas and chocolates).

The oil is mostly extracted by cold dry expressure, although there is a wet process as well, from the dried kernels or "copra."

Eight or ten nuts will yield a quart of oil. Boiling the pulp breaks open the cells, and as the oil is liberated it rises to the surface, and is skimmed off. The pulp is also submitted to pressure, and the cake or refuse left after the oil has been expressed is termed *poonac*, and is

used either for feeding stock or for manure.

Cochin, Ceylon, Madras, and Bengal are the chief seats of production.

The Cochin oil is the best, its superiority over the Ceylon product is owing to the fact that only the white sun-dried Copra is used in its manufacture. There is an inferior quality made at Calicut from unseasoned nuts, but it is only exported to Asiatic ports.

Colombo oil is not so much appreciated, because the fruits are there usually dried by smoke. Indeed, no pure oil can be expected from nuts dried in smoke.

In Jamaica, after being husked, the nuts are broken up, and the pieces laid near a fire until the meat will come away from the shell. Then the meat is washed, the thin black skin that lies between it and the shell not being removed. After being washed, the meat is grated, placed in a vat, boiling water poured over it, and the whole strained. When the water cools, the oil floats on top, and is skimmed off and cooled, and is ready for shipment. The oil sells for 6d. per pint bottle. It is now proposed to introduce into Jamaica the manufacture of cocoa nut butter.

When fresh, cocoa nut oil has the characteristic odour and sweet taste of the milky cocoa-nut itself, but soon turns strong, rancid, and unpleasant. It is composed largely of fatty acids, particularly the glyceride of lauric acid.

Although by Europeans it is considered too strong in flavour for table use, and seldom used even in kitchen cookery, it is regularly used instead of butter, lard, etc., by the poorer natives in Ceylon and other hot climates, where it can always be had fresh and sweet.

In these tropical countries it is always in a liquid state, fluid and limpid as water, but solidifies at about 60° Fahr., and consequently generally appears in England and other cold climates as a solid, opaque, and unctuous substance, like butter or lard, white and wax-like.

Vast quantities of this oil are burned in lamps throughout the whole Indian Archipelago, although it does not give a very clear light.

A tumbler half filled with water has oil poured in to the brim, two lighted sticks are the wicks, and every native glories in a display of lights about his grounds at the approach of night.

Although largely superseded by other oils in candlemaking, and by palm kernel oil, earth nut oil, etc., in soapmaking, it is still employed in these manufactures on account of its extreme whiteness, and its ability to absorb much more water than fat does. Being also very soluble in salt water, it is specially adapted for making *marine* soap; some is also employed in leather dressing and cosmetic manufacture.

Lately it has been used in the production of artificial butter, and the article is pronounced far superior to the ordinary oleomargarines. It is also said to be used in America in adulterating cheese, lard, and other oils.

The value of this butter or oil was originally discovered by a Dr. Schlunk, and first manufactured by P. Muller and Söhne, at Mannheim.

Consumption now stationary.

Value of Cochin, about 28/- per cwt.; Mauritius and Ceylon, 25/-.

Apply to C. Windschuegl & Co., 1 Leadenhall-street, London, E.C.

Cocoa Nuts.—There are two quite different products often called cocoa nuts—(1) the seeds or beans of *Theobroma cacao*, from which drinking cocoas and chocolates are made (see *Cocoa, Raw*); and (2) the large milky cocoa nuts (*Cocos nucifera*) sold by fruiterers (see *Coker Nuts*). Therefore, without some further distinguishing qualification, the term *cocoa nuts* may lead to confusion.

Cocoa Shells or **Husks.**—The chaff or skins of cacao beans separated from the nib. (See *Cocoa or Cacao Nibs.*)

An economical but somewhat bitter beverage called *Cocoa Tea* is made by boiling or stewing these shells in water. They are very popular in Ireland, where they are known as "miserables," and

are regularly transported from England for this purpose.

It has been found that different growths of cocoa contain varying proportions of husk, in comparison with nib or kernel, thus:—

Name as regards origin.	100 grams of seed consist of Kernels. Per cent.	Shells. Per cent.	Average weight of a seed unhusked. Gram.
Java cacao	92.9	7.1	1.236
St. Thomas cacao ...	92.3	7.7	1,348
Surinam cacao II. ...	91.4	8.6	1,149
Trinidad cacao	90.9	9.1	1,286
Para cacao	89.8	10.2	1,136
Porto Plata cacao ...	89.5	10.5	1,292
Hayti cacao	88.6	11.4	1,317
Bahia cacao	88.4	11.6	1,379
Puerto Cabello cacao ...	88.1	11.9	1,598
Surinam cacao I. ...	88.1	11.9	1,637
Machal-Guayaquil cacao	88.0	12.0	1,537
Arriba Guayaquil ...	87.0	13.0	1,628
Carupano cacao ...	86.8	13.2	1,469
Caracas cacao	86.6	13.4	1 504
Grenada cacao	86.6	13.4	1.230

So it is evident the amount of shell in a quantity of raw cocoa is a consideration for manufacturers.

Besides *theobromine*, the shells also contain a certain amount of *theine*, hence they are not at all to be despised.

The Customs duty on imported cocoa shells (if free from cocoa powder) is 2/- per cwt.

Sometimes they are ground and used in the manufacture of low-priced cocoa powders, also in the manufacture of some kinds of cattle foods. The lower priced chocolate confections are also now made pretty largely from cocoa shells ground up and mixed with glucose, starch, and colouring matter. The market value of cocoa shells varies considerably, and depends on their freshness, and whether consisting of mere husk or containing pieces of damaged nib, cocoa dust, etc., there being considerably more nutriment and less bitterness in the beverage made from the latter.

Apply to M. E. Holdsworth, 3 Norfolk-street, Bradford.

Cocoa Tea.—A name used in some districts for *Cocoa Shells*, or the beverage obtained by boiling or stewing them in water.

Confusion in Names.—A striking example of the ignorance of tropical products on the part of dwellers in temperate regions is instanced by the confusion still existing in the minds of shippers, merchants, tradesmen, and the public generally, regarding *Cacao*, *Coca*, *Coco*, *Cocoa*, *Cuca*, *Coker*, or *Koker*, etc., and the numerous compounds prepared therefrom.

It should be clearly remembered that the four following are quite separate classes of plants, and should not be confused:—

1. The coco, or *Caladium esculentum*, above referred to.

2. The chocolate tree or *Theobroma cacao*, and its congeners, from the beans of which are derived cocoa nibs, drinking cocoas, chocolates, cocoa essences, cocoatina, cocoa shells, Rock, Flake, Pearl, Homœopathic, etc., and a host of similar prepared cocoas, as well as cacao (or cocoa) butter.

3.—The coker (or cocoa) nut palm, *Cocos nucifera*, which produces the large hollow milky nuts, sold by fruiterers, costermongers, etc., and from which are obtained cocoanut oil, desiccated cokernut, copra, etc., the outer coarse fibrous husk of these nuts being also used for scrubbing floors, etc., as well as for making into cocoanut fibre matting. (See *Coker Nuts*.)

4. The coca (or cuca) bush, *Erythroxylon coca*, celebrated for its stimulating leaves, which, when chewed fresh, impart extraordinary endurance to the natives in South America, Ceylon, and other regions where it is grown. *Cocaine*, a very powerful drug, is also an extract from these leaves. These four plants and their products, although somewhat alike in name, are as distinct as the products of the walnut tree, the gooseberry bush, the potato plant, and the nettle. Each of them is fully described under its respective heading.

Cocoas de Mer—the French name for the curious double or Sea Coker Nuts, *Lodiocea Sechellarum*. These remarkable fruits are peculiar to the

Seychelles Islands, and grow nowhere else.

Cocos Petits. — French term for *cocoa beans.*

Cod-Fish. — Da. *Kabliau*; Du. *Kabeljaauw*; F. *Morue Cabillaud*; G. *Kabeljau*; It. *Baccala*; Port. *Bacalhao*; Rus. *Treska*; Sp. *Bacalao*; Sw. *Kabiljo*; W. *penfres.*

These deep-sea fish (*morrhua vulgaris*) abound most on the great Newfoundland Dogger Bank, a submarine plateau, some 600 miles long and 200 broad, but they are also hooked off Norfolk, Suffolk, Essex, Lincolnshire, and the Orkneys, Shetlands, &c., where they spawn about February and are in the best condition from October to Christmas.

The Cod is one of the best known of white-fleshed fish. Fishermen often keep them alive a long time. The "sound," or swimming bladder, is pierced with a needle and the air disengaged, so that when the fish is put into the well of the boat he sinks to the bottom and remains alive. They are afterwards turned into boxes 4 or 5 feet wide and deep, and about 10 feet long, and the boxes then floated or sunk in a tidal river, and thus left for six or eight weeks without food, but the boxes being perforated at the bottom the water is renewed as the tide goes in and out.

Sometimes old welled smacks are used for this purpose, these being kept in the tideway, or moving so as to produce a constant change.

They are only removed from these prisons as required for the markets, and are killed by a stroke on the head with a mallet. In some places a still more cruel way is adopted. After removal alive from the boat-well they are tied by the tail to a rope, many of them together, and sunk in deep water, their tails becoming sore and lacerated by the string. Cod in good condition should have the sides undulated, as if it were ribbed. It should be round and plump near the tail, the hollow behind the head should be deep, and the flesh very firm.

The cod fishery off Norway, Newfoundland and Iceland is an important industry. Loffoden is the great centre, yielding more than half the whole winter's catch.

Barrelled Cod.—A barrel contains about 40 fish. As soon as killed by an incision behind the gills the fish are beheaded, split open, cleansed, the roe and liver removed and placed in separate tubs. The fish are then salted and stowed in beds, head to tail, in the ship, a layer of salt being placed between each layer of fish. After a few days, when they have well drained, they are again salted and stowed. Finally they are packed in barrels, after being previously cut into large pieces.

Considerable quantities of cod, partly salted, wet and dry, are prepared at St. John's and sent to Southern Europe chiefly for consumption during Lent, and other fasts of Roman Catholics.

Cod-roe salted in barrels is a valuable commodity. France alone purchases £40,000 worth from Norway every year, as "rogue" or bait for the sardine and anchovy fisheries.

Dried Salt Cod.—(G. *Stockfisch.*) The cod, after being beheaded, opened, cleansed, and salted, is laid out on the shingle of the shore, or on low walls, and dried in the sun. Dry salt cod weigh about 5 lbs. apiece.

Pickled Cod is sold by the barrel; *Trawled Cod*, at per fish; *Hooked Cod*, by the score; and *Crimped Cod*, by the pound.

Cod Liver Oil and **Cod Oil.** — F. *Huile de Foie de Morue;* L. *Morrhuæ Oleum.*

The liver oil is pale yellow, with a bland, fishy taste, obtained from the liver of the common cod fish, *Gadus morrhua*, and allied species on the Northern coast of Norway, the great Dogger Bank of Newfoundland, the Rockall grounds of the outer Hebrides, also the Northern waters of Asia and America.

The average production is about a million gallons yearly, one hundred livers yielding one gallon of oil.

Bergen exports from 30 to 40 thousand barrels of liver oil a year, value £3 to £5 per barrel. The fish when landed are handed over to a fish-room keeper, whose duty it is to split open the fish and deposit the livers in small tubs holding 17 or 18 gallons each.

The tubs are soon afterwards collected from the different fish-rooms and conveyed to the manufactory. The livers are here thrown into tanks filled with clean cold water, and after being well washed and jerked over are placed on galvanised iron wire sieves to drain. They are next put into covered steam jacket pans and heated gently for about 45 minutes, and when again cooled the livers are found to have settled and more oil floating on the water.

The best oil is known as the non-freezing pale or shore oil, got by steaming to 180 deg. the fresh liver, and afterwards filtering or purifying it. The finest Loffoden non-freezing cod liver oil is generally worth 3s. 3d. to 3s. 6d. a gallon in London or Hull, and is usually imported in tin-lined barrels of 25 gallons each, the finest non-freezing Norwegian medicinal being 3d. to 6d. per gallon less.

When the livers cannot be treated fresh, putrefaction soon sets in, and the oil then obtained is somewhat nauseous, and known as *pale brown*, or *straits*, oil.

A still coarser grade is made when the livers of cod, herring, haddock, ling, coal fish, &c., are all boiled in water; this is very strong, and is termed *dark brown*, or *banks*. The latter quality is chiefly used in leather-making.

Cod liver oil is generally recommended for persons suffering from consumption, loss of flesh, rheumatism, general decay, and debility, at the rate of ½ oz. to 4 oz. a day. The best is rather nauseous to some constitutions at first, but may be taken in spirit, water, or milk, and the nausea first experienced soon subsides, till it can be taken in its pure state and in considerable quantities.

Its value is due to its comparatively easy and rapid assimilation. To completely mask the odour and taste would be worth a fortune to any man. The nearest success appears to be with oils of wintergreen, sassafras, bitter almonds, neroli, or clove.

Cod oil does not necessarily imply cod *liver* oil, but means oil obtained from any other part of the fish. Pure cod liver oil contains 95 to 98 per cent. of olein, palmitin, and stearin, has a specific gravity of .920 or .927, and will not freeze at 14 deg. A drop of sulphuric acid added to a few drops of the pure oil on a porcelain slab develops a violet colour, which soon changes to a yellowish or brownish red.

As already observed, the natural pale oil obtained from the fresh livers is doubtless the best; but as many of the pale oils lack medicinal value through having been artificially bleached, some authorities recommend the brown oil, notwithstanding that its colour is evidently due to decomposition. Apply to C. Windschuegl and Co., 1 Leadenhall Street, London, E.C.

Coffee.— Abysn. *Kaffa* or *Caffia*; Ar. *Bun*, *Karwah*; Da. *Kaffe*; Du. *Koffy*, *Koffiboonen*; Eth. *Bun*; F. and Sp., *Café*; Ger. *Kaffee*; It. and Port., *Caffé*; Malay, *Kopi*, *Kaffa*, or *Caffia*; Per. *Tochen*; Pol. *Kawa*; Rus. and Sw., *Koffe*; Tur. *Chaube* (the bean), or *Kahve* the infusion); W. *Coffi*. (See also *French Coffee*.)

Although everyone is familiar with coffee as a beverage, very few know much about its origin and history, as to where it was first grown, when introduced, how cultivated and cured.

It is supposed to have originated in Ethiopia, then found its way to Abyssinia as early as A.D. 875, and there are authentic accounts that it was introduced into Arabia from Southern Abyssinia by a Mahometan high priest about the year 1500. It has been found in a

wild state over numerous points of the African Continent, and has been traced through Syria, until in the year 1554 it became the favourite drink at Constantinople; for we read of the Oriental coffee-houses being thronged night and day, the lower classes actually begging money with which to buy it, and the refusing to supply a wife with a liberal amount of coffee was admitted in law as a valid excuse for divorce.

Bacon in 1600 writes: "They have in Turkey a drink called coffee which comforteth the brain and heart, and helpeth digestion!" About 1652 it made its first appearance in Great Britain, the first, or one of the first shops, for its sale being established in London by a Greek named Pasquet Rossie, the servant of an English merchant—a Mr. Daniel Edwards—who had got acquainted with the beverage in the East and brought a quantity home with him from Smyrna; but who to save himself from the annoyance of too numerous visitors anxious to taste the new drink, established his servant in a house in St. Michael's Alley, Cornhill, where it could be bought. Another account says coffee was sold in Oxford as early as 1640 by a Jew named Jacobs; and according to the journal of one Thomas Rugg, dated September, 1651, coffee was then "sold in a liquid state at the 'Sultaness' Head, a Cophee-house, by the Royal Exchange, London."

Evidently coffee-houses soon became fashionable places of resort and quite numerous all over London, poets, wits, politicians and philosophers making regular meeting-houses of them. Who has not read of the events at Will's, Button's, Paine's, Garraway's, and St. James's coffee-houses? Coffee is now spread over the civilised world; and consists of seeds, beans, or berries of the evergreen trees or shrubs belonging to the genus *Coffea*. It probably takes its name from Kaffia, the most productive coffee region in Abyssinia. The chief of the species are *C. Arabica*, a shrub growing four to eight feet high; *C. Liberica*, often growing 30 feet high; and the "*Marago-gipe*," as found in the province of that name in Brazil. Some authorities think the differences between them are merely due to climate and methods of cultivation.

The plants are usually raised from the seed in nurseries, and when one year old and about a foot high they are taken up with the earth around them and set out, 4 to 6 feet apart, in plantations. Here they are allowed to grow 5 to 10 feet high.

The main stem grows upright, and is covered with a light brown bark. The branches grow out horizontally and opposite each other, crossing at every point; the leaves, also opposite each other, are oblong in form, dark green, shining and leathery. They are 4 or 5 inches long, and 2 broad in the middle, sharp-pointed, and somewhat resemble Portugal laurel or bay leaves.

The flowers grow in white clusters at the root of the leaves and close to the branches. They are tubulous in shape, pleasant smelling (not unlike jessamine), and spread open at the top, where each flower is divided into five parts.

The tree begins to bear fruit at three years old, and yields ½lb. to 6lbs. yearly for 20 years. Usually three gatherings are made each year, the tree continuing to flower for eight months, and one may see buds, snow-white flowers, as well as green, yellow, and red ripe fruit, all on the tree at the same time.

The fruit or berries, which follow the flowers, grow in bunches, three to twelve in number, not unlike small cherries, at first green, and then yellow, but turn a dark red when ripe; each "cherry" or pulpy envelope, called the *epicarp*, enclosing in a pod two of the familiar nibs or berries which lie with their flat sides towards each other. The pods are called "cherries" when fresh gathered, because they grow inside a white pulp, thus covered by the husk or outside shell. In addition to the outer ligature, each berry has its own thick covering, or *endo-carp*, called "parchment."

When gathered, the coffee cherries are fermented, then hulled or uncovered,

and separated by machinery, the parchment is winnowed off, and the berries then dried in the sun, sized, and marketed.

Some of the pods contain only one berry, and this of rounder form than the others. These single berries, when picked out, or separated, are sold as "virgin," "male," or "*Pea-berry*" coffee.

Many attempts have been made to dry coffee by machinery, as in fruit evaporating, but without success. It is best dried in the sun; and in Jamaica, where showers of rain are sudden and frequent, it is exposed on large terraces or floors, where a large number of hands have to be waiting about in readiness to sweep the coffee off the "terraces" into covered sheds directly there is the least sign of rain.

There are about twenty different supposed species of the coffee plant, and many of them are being cultivated in several of the warmer regions of the world, wherever there is a mean annual temperature of about 70° Fahr. One labourer can look after about a thousand trees.

Brazil produces about two-thirds of all the coffee in the world, and most of that consumed in England comes from there.

It is the principal wealth of the States of Sao Paulo, Rio de Janerio, Bahia, Céara, Minas, and Geraes, which are the chief centres of production. Most of these growths are called "Santos," because they are shipped from that port. There seems to be some prejudice against Brazilian coffee, for it is seldom sold as such in trade circles, but is generally passed off under some other name.

Coffee plantations in Brazil are called *Cafezals*, and the berries are stripped by hand from the branches, and dropped into baskets or on sheets. Each tree yields from three to six pounds yearly.

Green berries, leaves, and twigs are often carelessly stripped off along with the ripe fruit, and these spoil many otherwise good samples.

The newly gathered berries have to pass through many processes. One is a washing in shallow cisterns filled with water, then drying on prepared ground, called the *terreiro* (terrace), which is completely open to the sun, and has a hard floor of clay, stone, or cement. Here the berries remain about three weeks, but carefully watched, and removed under shelter in case of rain.

The red outer skin, or *epicarp*, of the berry then turns black, forming a brittle hull or shell, and the white sweet pulp dries up, leaving on the inner bean a very thin covering, called the *pellicula*, or "silver skin." (This coat is very undesirable, and gives the berries a very dingy and dull appearance when roasted.) From the *terreiro* the berry is conveyed to bins, or *tulhas*, where it remains until it is to be passed through the machines which prepare it for market. Then it goes first to the *ventilador* (windmill), where the dirt, stones, and sticks are blown away as much as possible; and next to the *descascador*, where it is hulled. The bean thus liberated is passed to the *brunidor*, in which it is freed from the *pellicula* (silver skin), and polished; thence to the *separador*, where it is separated more or less completely, according to size and grade, and finally filled in bags of 60 kilos (132 lbs.) for shipment.

"*Washed Coffee*" is prepared differently. The fresh gathered "cherry" is placed in a tank of water, whence it passes with the water into the *despolpador*, which partially removes the pulp. It is then conveyed, still mixed with water, into the *batidor*, or pounder, where by means of revolving iron arms the rest of the pulp is removed. The bean has now a very light bluish tint, almost white, and after a few days of drying it is ready for bagging. Not much is cured in this way, although washed coffee is by reason of its lustrous, bright and silvery appearance a fancy sort of article, and mostly goes to France, yet it is really inferior in flavour to coffee cured the ordinary way, and where the bean is allowed to absorb the pulp.

Jamaica, Ceylon, and Turkey coffees are considered to be superior growths, especially the celebrated "Mocha,"

although very little of the genuine Arabian Mocha reaches England, and the coffees sold under that name are generally grown in other countries, but possibly from Mocha seed.

Of all the methods adopted for the curing and exploitation of coffee, that adopted in Ceylon is perhaps the most perfect. At the end of the day the gatherers draw to the pulp-house, and there the produce is received and measured. The coffee "cherries" then go through the process of pulping. A man takes his seat on a "cherry-loft," and through an aperture lets the cherries gradually pour into the "pulper" below. In this way the outer red skin is taken off and thrown to one side, while the coffee runs along wooden channels into large vats.

After twenty-four hours' fermentation it is washed, by coolies trampling and raking it, to remove the mucilage covering the bean. The "parchment coffee," as it is now called, is removed and spread out upon tables to dry. When partially dried it is dispatched in carts to the "curing works" for final treatment. After being unloaded it is spread out on the "barbecues" to thoroughly dry. It then goes to the "peeling mill," which removes the dry parchment-like skin or *endocarp*, in which each berry or bean is concealed; thence it passes through the "farmers," "sizers," and "separators."

The beans are delivered into boxes, showing the different sizes of "flats" and "peas" (flat and round coffee). This completes the work done by machinery.

Now the coffee goes to the "garbling room," where it is measured out to women—a bushel to each.

Every bean is supposed to be examined, and all that are discoloured, broken, or faulty in any way are thrown out, and go under the name of "Triage."

The coffee is now ready for packing, and this is done in double sacks, each one containing 1½ cwt. net. The bags are branded with the estate's name, also the class of coffee. The coffee is then carted or railed to the nearest port for shipment to Mincing Lane, London.

A large amount of coffee is grown in the Dutch East Indies, Java, Sumatra, and Celebes, but these are a Government monopoly, the prices being fixed and the sales conducted through a Dutch Company, called the *Nederlandsche Handels Maatschappy*.

Then come the Costa Rica, Dominica, Demerara, Bourbon, Java, Martinique, and Hayti growths.

Coffee growing has also been considerably extended of late in Ecuador, along the coast of which country new plantations are constantly being made. The New Hebrides are also growing and exporting a growth very similar to that of Caledonia. The kernels are smaller but have a very fine aroma.

Guatemala Coffee maintains a very high reputation. Its growth is carefully conducted and it is all handpicked, berry by berry, and not as in Brazil, torn from the branches so as to damage the tree.

African Coffee.—On the West Coast coffee growing is fast superseding the palm oil industry, and the berry nearly approaches in quality the Central American.

A fuller description of the several growths of coffee may be found under their respective names elsewhere in this book. (See *Mexican Coffee*, etc.)

As to colour the following may be classed as *green* coffees:—The Guadaloupe, Martinique, Porto Rico, Porto Cabello, Gonaives, St. Mark, Cape Haytien, Port-au Prince. The *yellow* include Java, Mysore, Demerara, Manilla, Wynaad, Jacmel, and Jeremie. Mocha and Bourbon are considered particularly tender sorts, but exceedingly delicious if properly roasted.

Porto Rico now produces about 30,000 tons of coffee a year; the best of it comes to Europe and the inferior goes to Cuba. Lowland growths yield more prolificly than the upland, or hill-grown; but the latter is superior, and Porto Rican is all hill-grown. The

principal district is among the hills of the western third of that island.

Approximate estimate of the world's supply yearly:—

	Tons.
Brazil	400,000
Central America	95,000
West Indies	41,000
Dutch East Indies ...	40,000
British East Indies ...	16,000
Africa	8,000
Other places	5,000
Total consumption ...	605,000

Approximate consumption of coffee *per capita* in each country:—

	lbs.
Holland	21·00
Denmark	13·89
Belgium	13·48
Norway	9·80
Canada	8·0
United States	7·61
Switzerland	7·03
The Cape	7·00
Sweden	6·11
West Indies	5·00
Germany	3·94
South America	3·00
Mexico and Central America	3·00
France	2·73
Austria	2·13
Australia	2·00
Greece	1·24
Italy	1·00
Great Britain and Ireland ...	·70
Spain	·31
Russia	·22

Arrival of new crops in England—*Asiatic* and *African* sorts in January and February; Central American and Brazilian about July; West Indian from June to September; East Indian about Christmas.

The judging of coffee is much more difficult than that of tea, for tea is always ready for the water; but raw coffee samples have each to be properly roasted and ground before testing.

The active principles in coffee are an essential oil, caffeine, and tannic acid.

The *caffeine* is identical with the *theine* of tea, and most authorities consider this alkaloid the most important constituent. They say it retards the waste of the tissues of the body, stimulates the brain to greater activity, and exhilarates without intoxicating. On the other hand, recent experiments by Heerlein have shown that coffee so far as its alkaloid (caffeine) is concerned is neither a food nor decreases the bodily waste, but rather excites and increases it; the distillate from coffee was also found to have no diminishing effect on the consumption of oxygen, hence he considers that coffee should be struck off the list of direct or indirect foods, and its action as an exciter of the nervous system alone be recognised.

According to the latest examinations of the coffee berry by Professors Virchow, Graham, Brillat-Savarin, etc., its constituents have been declared accountable for the highly nervous state of the present generation, as well as for the increased rate of cases of madness, apoplexy, and of stomach diseases.

The aromatic substances, however, by their exciting action on the taste and smell, produce an increased desire for the enjoyment and digestion of food.

Coffee has also been credited with having wonderful effects on cholera, as was proved during the epidemic in Hamburg in 1892.

Diarrhœa is soon stopped by it; often a single cup made very strong is sufficient, and asthma is greatly relieved by it.

As a disinfectant coffee is one of the most powerful known, even the fumes of sulphuretted hydrogen—worse than rotten eggs—are readily destroyed by it. A small quantity, fresh ground and thrown on a red-hot shovel, is sufficient to disinfect a sick room. It not only overpowers the noxious smells, but really absorbs and decomposes them.

Perhaps it is not so generally known as it should be that coffee is also a powerful antidote to nicotine, so that

the liberal use of the beverage must be very beneficial to heavy smokers of tobacco, cigars, etc.

Strong black coffee (*café noir*) taken immediately after an elaborate dinner may usefully check a digestion over-stimulated by alcohol, but at other times strong coffee may unduly retard digestion, and even produce fatal results. (See *Coffee Essences.*)

Notwithstanding the low price of coffee in this country, where the better qualities are cheaper than anywhere else in Europe, the consumption is diminishing.

For over thirty years it has been standing at about 14,000 tons a year, notwithstanding the ever-increasing population. The following figures show how the coffee trade of the United Kingdom has declined during the last twenty-seven years:—The total imports into Europe from all countries in 1879 was 337,654 tons, of which 77,416 tons came to the United Kingdom; in 1888 (the year the Emancipation Act in the Brazils was passed) the European imports were 381,700 tons, of which 47,700 tons came to the United Kingdom, while in 1895 European imports had increased to 490,800 tons, and the United Kingdom imports had fallen to 38,800 tons; or, in other words, in 1869 our imports were about 23 per cent. of the total European imports; in 1888 they had fallen to about 13 per cent.; while in 1895 they were only about 8 per cent.

The last three years show—

	1899.	1898.	1897.
Imports cwts.	1,008,263	922,252	756,590
Home Consumption „	268,370	250,818	248,501
Exports . „	686,632	558,916	451,333
Stocks in bond . „	353,000	307,000	207,000
Value of imp'ts	£3,470,796	£3,590,871	£3,585,674
„ exp'ts	2,295,714	2,132,535	1,932,485

The finest coffee in the world is sent to the English markets and the import duty being very low the retail price should bring it within the reach of all.

The finest Porto Rican France ever imported is not to be compared to the grand old Mysores, the delicate Ceylons, the powerful Costa Rican, New Granada, and Honduras growths, and the curiously-flavoured Mochas.

Yet, while the quantity of tea and cocoa consumed here grows larger every year, the beverage which is their only rival at the breakfast table is becoming less and less popular. In fact, within the last forty years the consumption has decreased to less than one-half, while tea and cocoa have increased three or four fold.

There must be something besides the competition of tea and cocoa which is retarding the use of coffee. Several reasons have been suggested for the change. The Chancellor of the Exchequer, in his Budget statement, 1896, says it is because tea is cheaper, requires less milk, and is easier for people to make. Others attribute the falling off to the excessive use of chicory; but the *Medical Journal*, in discussing the subject, maintains that there is no force in the chicory argument. Coffee, the writer says, is quite as frequently adulterated abroad as here, and this will be confirmed by anyone who has travelled far beyond the beaten tracks of the Continent. Nor is there any special art required in the making of good coffee, though when our medical organ adds that "to say that we don't know how to make good coffee is a fallacy and its terms a misstatement," it must be admitted that his own explanation almost involves a like assertion. One fact is we do not drink our coffee strong enough; we destroy the aroma and dissipate the flavour in an ocean of hot water.

As for the vile concoctions served as "coffee" at some hotels, refreshment bars, restaurants, cocoa rooms, etc., would it not be fairer all round if our food inspectors took cognisance of such beverages and analysed them?

The weak coffee often served up at the breakfast table is far more objec-

tionable to the genuine lover of coffee than a mixture of champagne and water would be to the connoisseur in wine. Coffee, in fact, is positively unpleasant when drunk as a weak infusion, and it is quite true that "the only way to drink coffee in large draughts is to make a small quantity of strong coffee and add to it an ample amount of hot milk."

But another, and perhaps much weightier, reason for the decrease in coffee consumption possibly exists in the fact that it is commonly too violently roasted—indeed, *burnt*. No doubt this produces a blacker, and therefore a seemingly stronger, infusion; but this is a delusion and the result a blunder, for during this quick and excessive roasting an empyreumatic product is generated, which causes the beverage to disagree with many stomachs, and renders dyspeptic persons unable to indulge in it in consequence of the heartburn and flatulence it produces. A grocer should try this on himself and friends, and compare the effects with those of coffee only mildly or slowly roasted, and with or without the addition of chicory.

Up to ten or twelve years ago the roasting of coffee in England was left almost entirely in the hands of the coffee roasters, a separate, and generally supposed to be entirely distinct, body from the coffee *dealers*, and much of the decrease in the popularity of coffee is attributed to the careless way in which this was done. The roasters cannot, however, be blamed. Their charge of 2s. 6d. per cwt. was too low, and to protect themselves from loss, while returning good weights to the dealers, the roasters had recourse to the system of low or light-coloured roasts, quickly done, which yielded a return of 1½ or 2 lbs. more than a perfect roast could do.

If too great heat be applied in roasting, or too much hurry, it becomes acrid, the volatile and aromatic flavour is injured, and it acquires a nasty burnt taste; if not sufficiently roasted the beverage has a raw green taste, has very little flavour, lies heavily on the stomach, and is very likely to produce sickness, the too rapid roasting being more of a surface roast than a thorough and perfect one.

It should be roasted until the beans are swelled to bursting along the middle of the flat side and are brittle enough to break between the fingers. Coffee roasted in this way has a delicious aroma and a rich brown colour. The great desideratum is its drinking qualities rather than its appearance. A great many have the idea that coffee looks handsome when it is light roasted. Purchasers are often misled by the brighter appearance of light roasted, and associate it with the best quality, when in fact it is far from it. Its drinking quality should never be sacrificed to colour. The best flavour should be given to coffee that it is possible to obtain, and people who send out light roasted, as a rule, are very short-sighted. "Cinnamon-roast" is a phrase much used and is popular with the trade, but it frequently lacks the flavour that can be found in dark roasted. Low grades sometimes make a very acceptable drink if fully roasted and all their aromatic qualities developed. Two considerations are recommended—thorough cleaning before roasting, and only quick roasting when the coffee is at the right stage of the process. This includes rapid cooling, without which browning continues unevenly in the cooling apparatus. It does not pay to put out a coffee which is insufficiently roasted for the sake of a handsome colour.

Properly roasted coffee should have a chocolate brown colour and look bright and oily. It swells to about one-third more than its original bulk, but loses about 15 per cent. in weight. It need never lose more than 18 per cent. in roasting. But if roasted a blackish-brown it loses from one-fifth to a quarter of its raw weight and gains 50 per cent. in bulk.

If kept after roasting it should always be kept in a very dry place, air tight,

and away from any strong smelling goods, as it loses flavour, attracts odours, and absorbs moisture very rapidly; even the raw berries placed near sugar quickly deteriorate in value, and pepper is worse still. The coffee aroma, being so very delicate and fugitive, if once lost or injured is irrecoverable. All attempts at its full preservation seem to be failures.

It should never be "tinned" whilst warm from roasting, or it will "sweat" and deteriorate quickly, especially if "high" roasted—the essential oil of the coffee being exuded, instead of being properly distributed. The labels, also, should be pasted on the tins and well dried before the coffee is packed into them, or the tin will be liable to rust.

The changes in the berry by roasting appear to be the volatilisation of a small portion of the caffeine, a partial change of the sugar into caramel, a general breaking up of the oil and albumen cells, with the extrication of gases and a large quantity of water, and the development of the very powerful and volatile aromatic substance, a single drop of which is sufficient to scent a large room with the familiar coffee odour.

In roasting the *green* coffees already mentioned, a bright and continuous fire is best, these coffees readily assuming a reddish colour; and it becomes necessary to moderate the fire and remove them when all the grains are chestnut-coloured.

For *yellow* coffees the fire must be less intense and kept at a uniform heat; these coffees, although more tender, require a longer and more delicate roasting. When the roasting is completed the coffee should be cooled as quickly as possible in order to preserve its colour, and the main secret of good coffee is only to roast and grind it very fine, and as required for immediate consumption.

It is not well, however, to send small quantities of fine coffee to a general roaster. Roasters, like millers, deal in large quantities, and though returning proper weight, the product is not always from the materials first sent.

To add a bright polish to roasted berries, and to close the pores so as to keep it fresh a longer time, a glazing material—a little sugar or oil—is sometimes used in roasting; perhaps the latter is best, for the sugar is apt to make the berries dark in colour and sticky.

When Coffee is Roasted with Sugar.—Messrs. A. Juckenack and A. Hikger have recently studied the alterations which take place when coffee is roasted with the addition of 8 or 9 per cent. of sugar, as practised in Germany. The chief results of their experiments are as follows:—

First.—*Caffeine:* In the ordinary process of roasting coffee loses about 21 per cent. of its caffeine, and about twice that quantity when roasted with sugar, owing to the higher temperature which is required to caramelize the sugar so as to glaze the coffee.

Second.—*Fat:* From 9 to 10 per cent. is lost during the ordinary process of roasting, and about 20 per cent. in the glazing process. As a rule, the different constants of the fat show an increase on roasting by either method.

Third.—*Organic matter:* In their experiments the loss on the average amounted to 11·375 per cent. in the ordinary roasting, while in the glazing process it was about 10 per cent., allowance being made for the amount of caramel. This was determined by Stutzer's method. Twenty grams of the glazed beans were shaken in a machine for five minutes with 500 grams of water at 20 degrees C. The liquid was filtered, and the residue in 250 c.c. of the filtrate, after deducting the ash, was taken as caramel. In this way, on coffee glazed with 9 per cent. of sugar, as against 1·25 per cent. of sugar, there was found 1·40 per cent. of caramel, as against 1·25 per cent. on a sample of Java coffee glazed with 8 per cent. of sugar.

A coffee "roasting syrup," for treating coffee berries of a poor colour, is in the market, but it seems to consist merely of about 26·21 per cent. of water, 45·80 per cent. of fermentable sugar (or dextraglucose), 37·45 per cent. of unfermentable substances and dextrin, and about 0·54 per cent. of ash. Among the great advantages claimed for it are preserving the aroma of the coffee a long time, making the decoction look stronger, and making the roasted berries to hold about 7 per cent. more water than they otherwise would.

Sometimes coffee berries are steamed after being roasted, and then coated with a film of glycerine to prevent drying. As much as 20 per cent. in weight may be dishonestly gained in this way.

Of all food substances probably none have been fabricated or adulterated with such pertinacity as coffee.

Finely ground date stones have often been used for adulterating ground coffee, and the particles being mostly opaque, they are not easy to detect; but chicory, a harmless root with no particular physiological action, is the chief adulterant, and is added to coffee because by its use a weak infusion of coffee has the appearance of a strong infusion. The consumer sees a dark brown liquid which tastes a little bitter, and imagines he is taking a good cup of coffee.

There are several ways of detecting chicory in coffee:—

1. A spoonful of pure ground coffee placed gently on the surface of a glass of cold water will float for some time and scarcely colour the water, but if it contains colouring matter or chicory it will quickly absorb water and sink, giving a reddish brown tint as it falls.

2. Take up a pinch of the powder and press it between the finger and thumb; if it cakes or adheres, so that you can roll it in a pellet, it is a sign of chicory or other sticky adulterant.

3. Stir a teaspoonful of the suspected powder in a tumbler of cold water, and instantly place it on the table; if the coffee be pure it will rise to the surface and scarcely colour the liquid, but if chicory be present it will settle to the bottom, and the colouring will be seen, because the ground coffee is an oily substance which prevents the water attacking it, whereas chicory has no such protection, and so it absorbs the water and sinks immediately.

4. Take a sample of the powder and add to it about ten times its weight of water; add a few drops of hydrochloric acid to acidulate the water, and then shake up the whole mixture. The coffee powder will float, and will impart a yellow straw tinge to the water; but chicory, on the other hand, is immediately acted upon, and will speedily form a deposit, and the caramel colouring will give the water a dark brown colour.

5. Moisten a little of the ground coffee with water, then spread it out on a plate or piece of glass and test the particles. The soft or pliable pieces betray adulteration. Coffee particles are *hard*, and do not turn soft in water.

6. Chicory in coffee is also easily recognised through the microscope. In America it is quite usual to sell a compound of one-third coffee, one-third chicory, and one-third roasted rye; but it is very apt to absorb moisture rapidly, and becomes hard and lumpy. Roasted pea flour is also used and roasted acorns, bread crusts, etc.

Pure coffee, well prepared, is undoubtedly one of the most delicious beverages, also an excellent safeguard against certain diseases, such as gout, gravel, etc.

The plan now being adopted by retailers who have best studied the coffee question is to *roast their own coffee* hour by hour, as required for sale and delivery; and there is no doubt that by this system of rapid roasting of small quantities the aroma is more perfectly developed and secured, while the little trouble and outlay soon pays for itself. Parnall and Sons, of Bristol (the Narrow Wine Street firm) seem to have

made a special study of the mills and roasters best adapted to the requirements of the modern grocer. Nothing attracts the interest of a consumer more than seeing how an article is prepared.

Raw coffees, however common, if kept dry, always improve with age, and turn a paler colour.

They are sometimes artificially coloured "light," "dark," "green," "yellow," and the best way to detect this is to wash the berries in warm water and rub them with a dry towel.

A judicious blend of different kinds also produces a better liquor than any single sort, but the mixture should, of course, only be made after roasting, for old and dry coffees require a shorter time to roast than new and moist ones. The same applies to "mild" and "strong" coffees; one would be burnt while the other would only be half-roasted. Coffee grinds best in dry weather; in fact, it is really an excellent barometer, for on the eve of a rainstorm the berries become so damp and tough that the grinding is a much more difficult operation.

Another fact not generally known may be here noted: Drop a lump of sugar into a cup of coffee without stirring; if the air bubbles rise and crowd into the centre of the cup a fine day may be expected, if around the sides of the cup rain, and if scattered irregularly over the surface variable weather is denoted.

In France, Holland, and some other places where the beverage is held in the highest esteem, the coffee is roasted till black, and is ground much finer than in England, and probably owes much of its superior aroma to this latter fact.

There appears to be considerable difference of opinion as to the best or proper way to prepare coffee for the table. Some say:—For every pint required use 1 oz pure coffee. Earthenware jugs are the best, and all metallic surfaces and strainers should be avoided. The jugs should be made hot before the coffee is put in, and the water freshly boiled. After pouring on the water it is necessary to stir it up well, and cover with a cloth to preserve the heat and aroma. It should then be left to stand about seven minutes, and may, after the scum has been removed with a spoon, be poured into another hot jug or cup. Use the best white sugar, and cream or hot milk. If these directions be followed, and the finest freshly roasted coffees used, the result will be satisfactory in the highest degree.

The above is undoubtedly an excellent way, but it would also be a further improvement to let the infusion stand a few minutes before stirring it about.

Others say that the best way is to suspend a flannel bag, or percolator, in the mouth of the coffee pot, then put in the powder, and pour the boiling water on to it *slowly*, so that each grain of coffee gets well exhausted by the continuous stream of hot water. In this case care should be taken that the water goes right through the powder, and not through the exposed upper sides of the bag.

Coffee should never be boiled, or its delicate aroma is rapidly carried off by the steam. The water should, of course, be actually boiling when poured over the coffee; a cupful or two should be poured out and returned again to the pot. Some experts think two ounces of the powder not too much for a pint of water, whilst others hold that *one* ounce of *pure coffee* is enough. There are connoisseurs, however, who prefer an altogether fuller and stronger beverage, which is probably best produced by using Hergl's automatic machine, yielding a liquor exceedingly fragrant, and clear as a glass of wine.

In making coffee the berry should not only be freshly and finely ground, but freshly roasted, and in private houses, let alone hotels, etc., in coffee-drinking countries if a servant were to roast the after-dinner coffee before the guests sat down she would be thought as incapable as would the servant in England who made the tea on Monday for drinking on Tuesday. The best

aroma of coffee is lost in a few hours after roasting.

A cup of coffee stirred with a pod of vanilla acquires a very agreeable flavour.

Arabian Coffee.—All travellers agree in their account of the delicacy and delicious flavour of the coffee used in the East. It is prepared thus:—Pound thoroughly in a mortar some coffee berries that have been freshly and quickly roasted. Pass them through a fine sieve two or three times, until at last you have a brown flour. Mix two teaspoonfuls of this flour and a small piece of cinnamon with two cupfuls of water. Boil it gently, then draw it back for a moment, and repeat this several times, until a cream rises to the top; then add half a cupful more boiling water, and it is ready to serve. Neither sugar nor milk are required.

To clarify the decoction the Arabs wrap a wet cloth round the coffee pot, but this method only answers when pure coffee is used.

The Brazilians should know how to prepare the drink, too. Instead of keeping it or boiling it they pack the finely ground berries in a conical bag, and pour two draughts of boiling hot water through the mass. They say that makes a real cup of coffee.

In Brazil the host tenders to a visitor the cup of coffee, as in Japan and the East the cup of tea is offered. This coffee is ground and roasted on the spot every time it is served.

In France, where the consumption of coffee has more than doubled during the last forty years, and where it is steadily increasing, the practice is to pour half a cup of cold water into the coffee pot 10 minutes or so after the coffee has been made.

Success in coffee making is best ensured by getting good coffee, *fresh roasted, fresh ground, fresh made with fresh water fresh boiled*, and fresh served.

Spent Coffee Berries.—These are berries which, having been used whole for the manufacture of coffee extracts, are afterwards dressed up and slightly roasted a second time, which gives them a very dark colour; but upon being treated with ether, the extract obtainable from these spent berries is less than 1 per cent. of the weight of the berries, instead of 13 to 14 per cent. obtainable from genuine coffee.

Indeed, inferior coffee berries are often picked out and coloured to resemble those of better quality. Thus also green South American berries are dyed to resemble brown Java. Ground coffee is also sometimes adulterated with spent and re-dried coffee grounds.

It is illegal to put anything but chicory into coffee mixtures unless a halfpenny stamp be affixed on each quarter pound sold.

A COFFEE TABLE.

Salvage Coffee.—Coffee which, salted and sodden with sea water, has been fished out of wrecked ships. It is then washed in lime water, coloured a rich brown with aniline dye, redried, and mixed with good coffee. Finally palmed off to unsuspecting retailers.

Gardner's Patent "Rapid" Sifter and Mixer. Freely used for coffees. Prices from 50s. to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Coffee Merchants.—John Cassell & Co. (importers and roasters), 80 Fenchurch Street, London; Jackson Bros. & Co., 14 St. Dunstan's Hill, London, E.C. Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; Pilkington & Co., 89 Whitechapel, Liverpool.

Coffee Biscuits.—Very good ones are made of corn-flour, sifted sugar, and cream.

They are pricked all over and baked in a moderate oven.

Coffee-crushed Sugar.—A name for crushed sugar, in which the lumps are of convenient size in sweetening coffee and tea.

Coffee Essences and Extracts.—These are generally concentrated infusions of coffee made by percolation with water, and then evaporated to about one-third of its bulk; it is afterwards mixed to the consistence of treacle with chicory and burnt sugar colouring.

Example.—(1.) 1lb. of ground coffee, ½ lb. chicory, and ¼ lb. of caramel make a superior article, and by pouring boiling water on a teaspoonful of this a cup of very fair coffee is ready in a moment.

The essence should be kept in well-corked bottles and in a cool place.

(2.) It may also be made thus:—Smash a pound of sound fresh roasted coffee berries (mixed kinds and free from oil), and put, while hot, into a lidded jug along with nearly half a thimbleful of salt, add a quart of boiling water and close the lid, then place the jug in a large pan of boiling water, so that the jug be entirely surrounded (bottom and sides) by the boiling water. Keep the pan boiling half an hour, then remove the pan to the side of the fire so as to simmer about five hours, then strain the contents of the jug through muslin, pour into bottles or jars, cork well, and keep air-tight.

3. A good extract is also obtained by distilling one part of pure ground coffee with five parts of water, and keeping them at a temperature of 209° C., in a very close vessel, for ten minutes, and then evaporating it until reduced to one part.

(4.) Some makers add one part of rectified spirits to nineteen parts of concentrated infusion of ordinary coffee, and prescribe one or two teaspoonfuls to a cup of boiling water.

(5) Take a pound of freshly roasted and ground coffee, pour over it a pint of hot water in which 2 ozs. of glycerine have been stirred. Let it stand a couple of hours in a very warm oven and in a tightly-closed vessel. Then percolate the product with boiling water until it measures a gallon. Shake it well and bottle while hot.

Creole Coffee is a distilled preparation, made by putting the requisite quantity of ground coffee in a filtered coffee-pot, into which it is pressed compactly; a little boiling water is then poured on and allowed to filter through the coffee, when more boiling water is poured on, the process being repeated several times. The result is a very rich extract, which is often preserved in air-tight jars. A single teaspoonful yields a rich and creamy cup of coffee when desired.

Another Process.—Put 1 lb. of freshly-ground coffee into a large funnel and pour upon it three litres of boiling water. Collect the percolate and set aside; then pass more boiling water through the marc (or "grounds") until the whole percolate of five litres is obtained. Evaporate this second percolate on a water-bath down to half a litre, add the reserved portion, and leave on the water-bath for twenty minutes. To this extract add 10 per cent. of glycerine.

Coffee extracts are, however, said by the Paris School of Pharmacy to be less valuable than fresh infusions prepared extemporaneously, owing probably to the dissipation of aromatic properties; they also contain only about one-tenth of the quantity of caffeine found in the roasted grains themselves. Some so-called essences of coffee are declared to be simply treacle and burnt sugar, flavoured with coffee; but if properly prepared from coffee a good essence should contain 1 to 2 per cent. of crystallised caffeine.

Coffee may also be too highly concentrated or used too strong. At a recent meeting in Paris of the Société Medicale des Hopitaux, Dr. Gilles de la Tourette and other medical men of note spoke of numerous cases of *caffeisme*, or coffee poisoning, that had come within their experience, especially from drinking coffee black and excessively strong. It produces a form of dyspepsia very like that of excessive tea drinking, both of which are hardly to be distinguished from alcoholic gastritis.

For best selling brands apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Coffee Finings. — (See "*Black Jack.*")

Coffee Imitations and Substitutes. — Roasted bread or biscuits, roasted figs or dates, roasted chicory root, and scores of other things have been used as substitutes for coffee, and will yield brown fragrant beverages not altogether unlike that of genuine coffee, because produced by substances similar to those of coffee—burnt sugar, and other burnt gummy and starchy matters.

Some of these beverages not only quench thirst as well as coffee, but they also produce certain refreshing effects on the persons who drink them. The United States seem to distance all competitors in coffee substitutes.

They have *Acorn Coffee*, *Almond Coffee*, *Bean Coffee*, *Beech-mast Coffee*, *Beet-root Coffee*, *Canada peas Coffee*, *Coffee-pulp Coffee*, *Currant-seed Coffee*, *Corsican Coffee* (from the roasted seeds of the knee-holly), *Egyptian Coffee* (chick peas), *German Coffee* (chicory), *Gooseberry-seed Coffee*, *Holly-berry Coffee*, *Rice Coffee*, *Rye Coffee*, *Sassafras Coffee*, and many others.

American coffees frequently contain roasted rye and pea flour, mixed with bran and molasses, or refuse biscuits and the waste products of bakeries. *Crust coffee*, a drink somewhat resembling coffee in colour, is made by steeping in water browned or toasted crusts of bread.

Bogus coffee beans also are sold at about one-third the price of the genuine berry. The ingredients (molasses, chicory, rye flour, etc.) are well mixed by machinery, and the compound then rolled out into thin sheets. These are cut into long, narrow strips, about an inch wide, and then put through a sort of lozenge machine, which stamps out the beans with bewildering smartness. They fall into square sieves, in which they are dried in a room warmed to 130 degrees, and finally baked brown. The rough bean thus produced is afterwards

smoothed and polished by friction, and finally roasted. The characteristic membrane, called "Coffee-flights," is, however, entirely absent, and of course it is only the ignorant or careless who are deceived. Other spurious coffee beans were lately made out of rye flour, glucose, and water, in much the same way in Philadelphia and Trenton.

To the eye of an expert detection is easy, but small retailers and the public are often cheated.

Artificial coffee berries have also been made of chicory and glucose, but all these bogus productions are much heavier than the genuine berries.

Acorn Coffee, made from roasted and ground acorns, is well known on the Continent, and especially in Southern France, where a species of *Quercus* is the chief beverage among the peasantry. In some places Dangway beans and lupine seeds are utilised in producing spurious coffees.

Negro or *Mogdad Coffee*, also known as *Fodegoza* or *Café du Soudan*, first introduced in 1876, is an infusion made from the roasted seeds of *Cassia occidentalis*, grown on the River Gambia.

It can scarcely be distinguished from a genuine coffee beverage, and is used by whole communities in Africa and other parts of the tropics, and is said to be very valuable as a febrifuge, but now seldom met with in England.

Sacca, or *Sultan Coffee*, is made from the husks of the coffee berry. These husks are also used to some extent in real coffee, and are even said to improve its flavour.

Swedish Coffee.—The seeds of the *Astragalus Bœticus*, used as coffee and cultivated for the purpose in parts of Germany and Hungary.

Dandelion Coffee or *Taraxacum*, *Elephant* or *Victoria Coffee*, *French Coffee*, *Malt Coffee*, *Pelotas Coffee* or *Coffee Surrogate*, *Coffee-leaf Tea*, *Kola Coffee*, etc., are each referred to under their respective names.

Whey Coffee is a substitute consisting of whey evaporated to a thick paste and then rolled into cakes. It is afterwards broken up and mixed with coffee.

Mochara Coffee is simply made from ripe figs, roasted and pulverised, so as to be sold at about half the price of genuine coffee.

In Brazil and other South American countries the fruit of the wax palm, being very rich in *caffeine* and possessing nutritive properties, is sold as coffee. In New Zealand the berries of the *Coprosma* are used.

Celery Coffee is a compound which is, or lately was, made in Glasgow.

Date Coffee is referred to under its own heading.

The Regulations as to Imitation Coffees in this country are set forth in the following:—

GENERAL ORDER.

Inland Revenue Office, Somerset House, London, W.C.,
August 14th, 1882.

Ordered.—That notice be taken by the officers of this Revenue, and by every person who shall sell or prepare chicory or other articles, in imitation of, or for use as, coffee or chicory, of the following changes made in the law by the Customs and Inland Revenue Act, 1882, 45 and 46 Vict., cap. 41. The duties of Customs or Excise hitherto chargeable on vegetable substances, other than coffee or chicory, intended to be used as coffee or chicory, have been repealed. And in lieu thereof, an Excise duty of one halfpenny on every quarter of a pound is now chargeable on every article made in imitation of, or prepared for, the purpose of being used as coffee or chicory, and on all mixtures of coffee or chicory with such articles. This duty is to be paid by means of adhesive Excise labels, and such labels are deemed to be stamps within the provisions of the Stamp Duties Management Act of 1870 which imposes severe penalties upon any person who shall make or use any forged stamp, or shall deal in, hawk, or sell any stamps, without being duly licensed to do so. No article, substance, or mixture, as aforesaid, shall be sold or exposed for sale, or offered or kept readied for sale, or delivered out of the custody of, or possession of, any preparer, manufacturer, or importer thereof, except under the following conditions:—(

The article, substance, or mixture shall be placed in packets, each containing a quarter of a pound, or any number of quarters of pounds. (*b*) Each packet shall have affixed thereto a label or labels, which shall not have been before used, denoting the proper amount of duty payable according to the weight thereof. (*c*) Such label or labels shall be affixed so that the whole shall adhere to the packet, and so that the packet cannot be opened without tearing or destroying the label or labels. (*d*) When more than one label is affixed to any packet, they shall be so fixed that every label shall be wholly or partially visible. (*e*) Every packet containing, or purporting to contain, coffee with any other article or substance mixed therewith, shall have affixed thereto a label denoting in letters of not less size than the largest letters affixed to, or imprinted on, such label, the proper names of the several articles of which such mixture is composed. The label denoting the ingredients of the mixture must be provided by the trader himself.

Any person who shall sell, or expose for sale, or offer or keep ready for sale, or deliver out of his custody or possession any such article or mixture as aforesaid, otherwise than in conformity with the above conditions, shall forfeit the same, and incur a fine of £20. If any person who shall prepare, manufacture, sell, keep for sale, or import any article, or substance, or mixture, upon which the above-named Excise duty is imposed, shall buy, receive, or have in his possession any Excise label provided under the Act, which shall have been before used, or any portion of such a label, whether loose or affixed to a packet, he shall incur a penalty of £100, and such label or portion of a label shall be seized. In any proceedings for the recovery of the fine, proof that any label had not been before used shall lie upon the defendant. The Excise duty labels will be provided by the Commissioners of Inland Revenue, and will be supplied on application and payment of the duty, by the Comptroller of Stamps and Stores, Somerset House, London, and by Collectors of Inland Revenue in the country. The labels will be of two denominations, viz., one halfpenny and one penny each, and will be issued in sheets containing forty in each sheet. Wholesale coffee or chicory dealers, roasters of chicory or coffee, chicory dryers, and persons making any substitute for coffee or chicory, or mixtures therewith, must be furnished with a copy of this order, and officers must prepare schemes in the Store and General Register, in which they must enter the names of such traders, and the date of furnishing them with a copy of this order. It will be observed that the Customs and Excise duties on chicory, as imported, or as grown in the United Kingdom, remain as at present. Chicory dryers will, therefore, be liable to duty as hitherto, but such traders must understand that if any admixture of other articles occurs in the process of drying or roasting, they will not be entitled to sell such mixture without the required Excise duty label being affixed upon the package. Pure coffee or pure chicory may be sold without labels as hitherto; a mixture of coffee and chicory must, however, be labelled as required by the Adulteration of Food Acts, but no Excise label will be necessary.

By the Board,

CHARLES B. FORSEY.

Coffee-leaf Tea. — A refreshing and restorative infusion prepared in Java, Sumatra, and other parts of the Eastern Archipelago from the roasted leaves of the ordinary coffee plant (*Coffea Arabica*).

The leaves contain the same stimulating principle as the coffee berry—*caffeine* or *Theine*. Before infusion they somewhat resemble true tea leaves (*Camellia thea*), but afterwards they are easily distinguished, lacking as they do the serrated or notched edges of the ordinary tea leaf. They also possess besides the alkaloid a full berry-like flavour and very little of tannin. In fact, when prepared, coffee-leaf tea closely resembles the seed beverage in many points, but is somewhat pungent and bitter, and, although the natives seem to prefer the liquor from the leaves to that prepared from the ground

beans, it has an unpleasant senna-like odour.

These roasted leaves are sold in Sumatra at about 1½ per lb., and used by some millions of people, but only a few packages—"half-chests" from Ceylon—have reached our own markets, and these have so far been allowed to pass *duty free*.

Cognac. — (See also *Brandy*) — A celebrated kind of brandy made at the town of Cognac, and in the Departments of Charente and Charente Inferieure, France, and properly is the distilment obtained from white wines, especially from the grape known as *Folle blanche*, which only yields a poor quality of fruit, not much larger than ordinary currants. In good years this wine will produce a fifth of spirit at 22° to 23°, but in bad years nine or ten parts of wine are required to produce one of Cognac.

The best produce of the still is known as *Eau de Vie Première*, and is remarkable for its delicate rich bouquet and flavour, rendering it pre-eminent above all other makes of brandy. It is said to owe much of its excellence to the care exercised in fermenting the wine, that it be not impregnated with an acrid oil which is present in the skin of the grape, a drop of which oil would suffice to deteriorate a large quantity of good brandy.

But it is a well-known fact that not nearly so much real Cognac is made in the Charente districts as would supply the demand, and that comparatively little of the so-called Cognac is genuine. In fact seven-eighths of the spirit exported from France under the name of *Cognac* is made in other districts, while some are adulterated compounds known there as *façon Cognac* (imitation Cognac). These latter generally contain some 40 per cent. of alcohol obtained from grain, beet-root, or potatoes (*Berlin spirit*), and 40 per cent. of other substances which are used to make it like real Cognac. Indeed, analysts have shown that there is no reliable means of distinguishing real Cognac distilled from wine from the spurious stuff. Some are made up from potato-spirit, water, "essence of Cognac," and a little tincture of vanilla.

The word "Cognac" is, however, only legitimately applied to French brandy which has been distilled from wine, wherever made, and the French Courts have ruled that the word need not be confined to the *eaux de vie* of Charente or any other particular district; although this ruling is curiously inconsistent with the law as to "Champagne," which word must only be applied to wine grown in the Champagne district.

The old reputation of French brandy is now altogether demoralised, and both dealers and the public generally were strongly advised by the Health Congress (1899) to change on to the Spanish brandy, which is more reliable.

Cohune Oil.— Obtained from the nut of a kind of resinous palm tree. It is considered superior to cocoanut oil; and in British Honduras, where there are some two million acres covered with these graceful trees, the oil is largely used for domestic and cooking purposes in the families of the numerous mahogany and logwood cutters.

Coker, Koker, or Cocoa Nuts. —Du. *Kokosnooten*; F. *Noix de Coco*; Ger. *Kokosnooten*; It. *Noce di Coco*; Port. *Cocos*; Rus. *Kokos*; Sp. *Nuez de Coco*. (See also *Pigmy Nuts*.) Also known as *Coco de Mer*, and *Monkey Nuts*, but must not be confounded with the nuts, beans, or seeds of *Theobroma cocoa*, used for making chocolates and drinking cocoas.

"Coco" would, after all, be the right spelling for these nuts, because "coco" is the Portuguese word for monkey, and the end of the nut strongly resembles a monkey's head. They are the fruit of a species of palm tree, *Cocos nucifera*, which grows 50 to 90 feet high in nearly all of the tropical climes, but perhaps most extensively about Nassau and Jamaica in the West Indies, and in Samoa. It requires plenty of hot sunshine and open air, and seems to prefer a low, sandy shore, where the roots can strike

into sea-water, while the top always leans sea-wards, so that the ripe fruit often falls into the sea, to be carried in its wooden case by the waves till it plants and propagates itself on some other distant shore. Some recent travellers deny that the trees grow wild in this way, and aver that they require very careful planting.

The tree has no branches, but is crowned with a bunch of sword-like leaves, each leaf being 12 to 14 feet in length, and having a very strong mid-rib. A tree yields annually about 100 nuts, arranged in clusters of about a dozen each near the top, and bears for some 150 years. It is the most widely-distributed of all tropical growths, and it is questionable whether there is any species of tree so useful. Residents in temperate zones have little idea of its immense importance in tropical countries. An Indian with a garden containing twelve of these coker-nut trees and a couple of jack trees, *Artocarpus integrifolia*, considers himself a comparatively independent gentleman.

A few years ago the Dutch Government ordered a census of the coker-nut trees in Java and Madeira, which footed up to over twenty millions—being an average of three to every native inhabitant.

One species (*Lodoicea*), cultivated in the Seychelles, produces double nuts.

Coker-nut culture in Florida is on the increase. There are about 250,000 palms of all ages on the east coast, most of which are bearing. Growers bury the nuts until they sprout, and then plant them in holes about two feet deep. The tree begins to fruit in from five to seven years. There are trees at Key West fifty years old. On the shores of Lake Worth there are over 50,000 trees, old and young.

The outer husks of the nut are very rough, and it would be no easy task for a novice to open a dozen or two. They are usually stripped off by men using two fine-pointed steel chisels, and who, by constant practice, are able to open 10 to 12 hundred nuts per day. The husks are very useful, being steeped in water the dry dusty substance mixed with the fibres is separated, and the fibre is spun into a valuable species of yarn, known as coir, which is used very extensively in making "sennet" or braided twine, ropes, cordage, bagging, hammocks, breech cloths, hats, matting, coarse brushes, towels, bed covers, and stuffing for mattresses and cushions. Sometimes these outer husks, split in two, are used as scrubbers for floors, or are carved into masks and similar grotesque figures; even if burnt, the ashes supply an alkali for making soap. The outer husk of a coker-nut, sawn in two across the grain of the fibre, forms an excellent wood polisher.

The inner shells, when emptied of their pulp and liquor, form drinking cups, water bowls, or "hubble-bubbles," as they are called in India, carved vases, sugar basins, tea-pots, spoons, and other domestic utensils.

The juice of the unexpanded flowers makes "Tari" or "toddy" for the natives; boiled down, it yields honey and sugar; and fermented, it yields a spirit, and passes under the name of *arrack*, etc., and this is used extensively by bakers in India instead of yeast; or, if allowed to undergo the acetous fermentation as vinegar, and boiled down while fresh, with a little lime, the juice yields *Jaggery*. It is this milk or creamy substance that solidifies and afterwards forms the white pulp. In a fresh state, the pulp is either eaten raw or dried hard and cured in the sun for exportation, the latter being known here as *Copra* and in Ceylon as *Copperah* (which see). Coker-nut pulp is also grated and used for soup, or *potage au coco*. It also yields Coker-nut oil or butter, while large quantities are now sweetened and dried for use in confectionery, cakes, biscuits, etc. (See *Desiccated Coker-Nut*.)

In the younger nuts there is a delicious jelly, clear, like albumen in an egg, which has a very beneficial effect when taken by persons suffering from fever and other ailments. Even the juice of young and green nuts, instead of being sour, is very delicious and wholesome,

clear as water, cold, and sparkling, also just sweet enough to be agreeable, besides being remarkably refreshing and fattening. The young buds taste very like cabbage when boiled. The bark of the tree is used by the natives in erecting their dwellings, its leaves as roofing material, boat oars, fans, etc., and the leaf-stalk as a gauze for windows. It is also used for making lanterns, masks for screening the face from the sun, wickerwork baskets, and as writing material, sail-cloth, torches, brooms, ropes, matting, etc. The cocoa-nut palm tree, very porous and spongy in its green state, also yields "porcupine wood," excellent for building and for furniture: and when thoroughly seasoned will endure for a long time underground, and, therefore, is very suitable for posts.

If the body of the tree be bored there exudes from the wound a white liquor, called *Palm Wine*—very sweet when fresh and kept a few hours it becomes still more poignant and agreeable; but in twenty-four hours it changes into vinegar. In fact, a home and its furniture, food, drink, and heat, clothing, boats, and weapons, may all be derived from this one tree, the ever present friend of the tropical native.

The nuts with the outer husk on are imported from West Indies, Ceylon, Africa, etc., loose, but if without the outer husk, they are generally imported in bags containing 75 to 150, according to the size of the nuts.

The cocoanut industry in Zanzibar stands well with the European markets, and seems to have an assured future. In the annual report of the Agricultural Department it is pointed out that the Dunga trees yield about 30 nuts per year, and the Machui, which are older, 40 nuts. Gathering costs about four rupees per thousand nuts, and the nuts can be sold on the spot for from 20 to 22 rupees per thousand; there is, therefore, a profit of, say, 17 rupees per thousand. Now, a thousand nuts are the product of 33 trees, at 30 nuts per tree. Trees are planted 35 feet apart, which is 35 trees to the acre. Roughly, it may be taken that 1,000 nuts are the produce of an acre of land, and give a net return of 17 rupees (£1 2s. 8d.) per acre, or half a rupee per tree. There are no other outgoings to be charged to cocoanuts, as the trees are not cultivated in Zanzibar. Mr. Last has more than trebled the yield of his trees at Mangapwani, which he attributes to having dug the ground round them. It is found at Dunga that digging and mulching with grass can be done for about three pice per tree; the margin of profit, therefore, as shown by Mr. Last's figures, is considerable.

For some time before Whit-Monday a certain district of Houndsditch, in London, always teams with costers buying their cocoanuts for the holiday season. This period of activity lasts for two weeks, culminating in a Whit-Sunday sale, which starts in the early morning and lasts till two or three in the afternoon. The nuts are brought from Trinidad and Colombo in sailing vessels of about 400 tons, each vessel carrying about 500,000 nuts. Their cargoes are usually discharged in the Regent's Canal Basin, Limehouse, where from 8,000,000 to 10,000,000 nuts are received every year. Up to recently every cocoanut which arrived in London had to be husked, but now Costa Rica sends a large quantity already husked off with the exception of a little piece fitting over the "eyes," which is left in order to keep the nut sweet. After the husking, which is effected by a man working with two chisel-like tools, one in each hand, and costs 6d. per hundred, the nuts pass to the sorter, and by him are divided into the following different classes, a bin for each being reserved:—"Large milky," "middles," "smalls," "milky growers," and "chats." The first three grades indicate good nuts of different sizes; "growers" are those which are "sprahtin', fairly sprahtin'," like the moustache in the song; whil-

"chats" are a very small and thin variety. The sorter also separates the good nuts from the bad by subjecting every one to the test of being pressed against some hard surface, when, if the "eye" bulges, it is what is known as "weak-eyed," and only fit for oil or soapmaking. The prices realised per hundred are:—Large, 14s; middles, 12s.; smalls, 10s.; growers and chats, 5s. But the coster prefers unsorted lots of Ceylon nuts in bags of matting containing any number from 75 to 100, for which he pays about 5s. per bag. The cocoanut-shy man generally buys wholesale, the patriarch of the family investing in, say, 5,000 or 6,000 nuts, and dividing them among his relations.

Small lots are commonly sold by the dozen. The "milky," *i.e.*, the sound and fresh ones, fetch the best price, while "dry," *i.e.*, old or damaged nuts, are sold much cheaper.

The sweetest in flavour and best for confectioners, biscuit makers, and others, are those from Trinidad, though Ceylon runs them very close in quality. Apply to J. Agate, importer, 25 Wellington Street, Covent Garden, London, W.C.

Cokos.—See *Temperance Drinks.*

Cola Nuts. — See *Kola Nuts.*

Cold Cream. — A cooling unguent for the skin, usually made of almond oil, spermaceti, white wax, and rose water. Mix:—12·5 gm. spermaceti, 10 gm. Japan wax, 62 c.c. almond oil, 19 c.c. rose water (strong), and 0·5 gm. borax.

Cold Water Soaps. — This term was originally confined to soaps made from very soft fatty materials, but containing very little water; then similar products were largely made by artificially depriving "neat soap," fitted in the ordinary way, of about one-third of its 30 per cent. of water, by exposing it to prolonged fire-heat. These soaps may be kept indefinitely without losing weight, and are truly economical, provided they are not used with hot water. Latterly, however, the term cold water soap has been extended to heavily watered makes which run away quickly, espcially in hot water. Hence buyers should be careful what kind of soaps they get under this name. "*Health Soap*" is a good example of what a Cold Water Soap should be.

Collared Meats.—*Collared Beef* is that from which the bones have been removed. It is afterwards rolled or bound with string or tape, and braized with various preparations of herbs, spices, wine, etc., and finally pressed under heavy weights.

Collared Head put up in tins is becoming very popular through housekeepers being able to re-melt the contents and put in their own fancy moulds.

Collared Brawn is described under *Brawn.*

Collis Browne's Chlorodyne. —An ounce bottle contains as the important ingredients 6 grains of hydrochlorate of morphia, 6 drams of chloroform, and a small quantity of Indian hemp. (*Hygiene*, May 27th, 1893.)

Colonel Skinner's Chutney.—(See also *Chutneys.*) This is a highly esteemed variety of Anglo-Indian pickle, in which the fruits are cut in large slices, moderately sweet, but pretty hot. The genuine is made at Bombay.

Colophony, a name for *Resin.*

Colours for Foods, Drinks, etc. —F., *Couleurs inoffensives;* G., *Giftfreie Farben;* It., *Colori inoffensivi;* Sp., *Colores inoffensivas;* Port., *Cores.*

These substances, whether in powder, paste, or liquid form should always be harmless, and all persons engaged in preparing or vending articles of food, drinks, etc., should ever beware of poisonous or injurious colourings.

Sugar-boilers, pastrycooks, and others using colours should bear in mind that it is perfectly feasible to colour confectionery in most brilliant tints without having recourse to any

deleterious dyes. The old "caramellists," or confectioners to the princes and prelates of the 18th century, knew these things well, and equally familiar with them were the abbesses of the convents renowned for their "compotes" and "conserves."

In strawberry, raspberry, and plum ices the fruit itself gives not only the desired hue, but flavour as well, and the red can easily be heightened by the addition of crushed currants.

Yellow.—Although sugar coloured by the addition of aniline dyes is often sold to confectioners as "egg colouring," etc., no better yellow can be found than that afforded by hay saffron (or safflowers) which is a most salubrious drug, and which the wise Italians always add to their *risotto*, not only to make it look pretty, but to make it wholesome. Persian or French "yellow-berries," *Rhamnus infectorius*, are also quite harmless vegetable products, and either extracted with alcohol or treated with alum or cream of tartar yield a very bright yellow.

Turmeric root, dried and ground to powder, is a quite legitimate and effective yellow, suited for many uses, while *Logwood chips*, from Yucatan, produce, with a little acid, a very suitable yellow for use in sugar boiling.

Green.—(1) Extract of saffron 1·20, with solution of indigo. The colour is improved by a few drops of chloroform; or (2) tincture of saffron, with solution of indigo carmine mixed, with an equal volume of glycerine. (3) Chlorophyll in alcoholic solution. (4) Spinach juice.

A most vivid *green* can be obtained from spinach water or finely chopped and decocted parsley, and it is the last-named vegetable which gives the emerald green colour to the famous *Sauce verte* of the Restaurant Lucas at Paris.

Sap green is also serviceable for many purposes. For *blue* the best ultramarine, indigo, Prussian blue, or smalts are good; and for *violet* litmus supplies a ready tinge.

Red.—Mix 6 parts of cochineal with 2 parts of chalk and rub well together, then add gradually 12 parts of 95 per cent. alcohol, and finally 15 parts of water; set aside for a time and then filter. Or dissolve 2 parts of carmine in 12 parts of potash solution, and dilute with 86 parts of water.

A *pink* tint, likewise, red, scarlet, or crimson, can be obtained from *cochineal*, but no confectioner in his senses would think of using red lead for crimson or even gamboge for yellow, the last being hot and nauseous to the taste, besides being purgative, although it has often been used for imparting a primrose or light straw tint in lozenges and other confections.

There are two well-marked classes of red pigment in the vegetable kingdom—the wine-red, which occurs in *Ampelopsis*, *Rhastyphina*, *Comus sanguinea*, etc., and the carrot-red, in the beet, *Amaranthus*, fruit of *Phytolacca*, etc.

The mallow violets, as in *Coleus*, etc., form another group.

In black grapes and in whortleberries there are two pigments, one of which is a glucoside; the colouring matter of yellow vine leaves is a glucoside, as is also that of the mallow.

Chrome yellow (chromate of lead) was formerly largely employed for colouring sweets, and even pastry, and it is still used by some people; but it is classed as "an adulterant," and should be discarded.

Yolkine is a fancy name given to an aniline yellow.

Caramel, or burnt sugar colouring, is a very useful and perfectly harmless substance, and so are most of the compounds made up at the special laboratories for essences, extracts, and vegetable colours.

The use of aniline, or tar colours, in foods, etc., is prohibited, and have been shown by the Government analysts to be very injurious when imperfectly prepared. If discovered, the

user is liable to severe penalties under the "Adulteration Act," 35 and 36 Vic., chap. 74. Still it is pretty certain these bright and powerful dyes are often employed in paste, powder, or liquid form by many confectioners and cheap jam manufacturers, and when pure have not been proved to be injurious.

Gardner's patent "Rapid" sifter and mixer, freely used for above. Prices from 50s. to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Colours for Paints, etc. — F., *Couleurs;* G., *Farben;* Sp., *Colores.* (See also *Paints.*)

Most of these are dealt with under their respective names.

Every quarter of the globe is ransacked for the materials—animal, vegetable, and mineral—employed in the manufacture of the colours one finds in a paint box, and the old countries of the world are still resorted to. From the cochineal insects are obtained the gorgeous carmines, as well as the crimson, scarlet, and purple lakes. Sepia is the inky fluid discharged by the cuttle-fish, to render the water opaque for its own concealment when attacked. Ivory-black and bone-black are made out of ivory chips. The exquisite Prussian blue is got by fusing horses' hoofs and other refuse animal matter with impure potassium carbonate; it was discovered by an accident. In the vegetable kingdom are included the lakes, derived from roots, barks, and gums. Blue-black is from the charcoal of the vine-stalk. Lamp-black is soot from certain resinous substances. From the madder plant, which grows in Hindustan, is manufactured Turkey red. Gamboge comes from the yellow sap of a tree, which the natives of Siam catch in cocoanut shells. Raw sienna is the natural earth from the neighbourhood of Sienna, Italy. When burned it is burned sienna. Raw umber is an earth from Umbria, and is also burned. To these vegetable pigments may probably be added India-ink, which is said to be made from burned camphor, but the ingredients are not always the same; an inferior quality consists of lamp-black and size or animal glue. The Chinese, who alone can produce the genuine, will not reveal the secret of its composition; they do not use animal glue, but vegetable juices, which render it more brilliant and lasting. Mastic, the base of the varnish so called, is from the gum of the mastic tree, indigenous to the Grecian Archipelago. Bistre is the soot of wood ashes. Of real ultramarine but little is found in the market. It is obtained from the precious lapis lazuli, and commands a fabulous price. Chinese white is zinc. Scarlet is iodide of mercury; and cinnabar, or native vermilion, is from quicksilver ore.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

Coltsfoot Preparations. — These are numerous, taking the form of liquids and solids, lozenges, rocks, pipes, tobaccos, etc.

Coltsfoot itself, *Tussilago farfara*, or *Ungula Caballina*, has many *aliases*, among which are cough-wort, asses-foot, foals-foot, horse-hoof, bulls-foot, etc., and is a very common plant in waste places, clay banks, and brick-fields, which it often brightens up with its yellow flowers.

The downy substance on the undersides of its leaves used to be, in the old days of flint and steel, dipped in a solution of saltpetre, dried, and used as tinder. The leaves and roots have long been credited with possessing great virtues for coughs, colds, wheezing, shortness of breath, and rheumatic affections. The prepared leaves are also largely used in *British Herb Tobacco*, and have been recommended to be smoked in cases of asthma and difficult breathing.

Coltsfoot Rock may be made as fol-

lows:—Soak 3 ozs. of gum tragacanth in water till soft, pass through a sieve, then add 1 quart of gum arabic water (strong), 2 to 2½lbs. of liquorice paste, dissolved, ¼ oz. of oil of anise, and a strong flavouring of lemon. Work enough sugar with this to form a stiff paste, then pass through the forcer, same as used by bakers for jumbles, using a star plate; when through the forcer cut in lengths and dry.

It is usual in large factories to utilise all sugar waste from the lozenge and pan rooms in the manufacture of coltsfoot rock. The waste is thoroughly dried in a warm stove, then ground in a sugar mill, and passed through a fine hair sieve. A cwt. of the rock may be made from 100lbs. ground sugar waste, 2lbs. gelatine, 3 qts. liquid gum, 2 qts. boiling water, 1lb. extract of liquorice, with a little coltsfoot flavouring and brown colouring.

Coltsfoot Lozenges are made from the same paste.

Acidulated Coltsfoot is made by the simple addition of ¼ oz. tartaric acid to each pound of sugar used.

Colza Oil. — Ger., *Rueboel, Cazaoel;* F., *Huile de Colza;* It., *Oli di Colza;* Sp., *Aceite de Colsa.*

The oil expressed from rape seed—a species of cabbage, *Brassica oleracea.* A large quantity is grown in Roumania, particularly about Ilfor, Botoshany, Teleorman, and Jalomitza. The oil is used for burning in lamps and many other purposes.

This article being frequently met with in very inferior condition, it may be explained that the seed itself should be pure and clean before the oil is extracted, and the latter should then be freed of all albumen, mucous and other fluids, or the oil will not burn well. The name of colza is also applied to a mineral oil of commerce. Colza seed is also grown in France, and the French refined oil is conveniently put up and sold in gallon tins.

Colza seed, especially that from Germany, is often adulterated with "*Sauve*" (grains of a variety of mustard), and also with *Brassica juncea*, both being artificially coloured blue, with a coating of a kind of litmus.

To detect the fraud maceration in water is sufficient, a blue solution being thus afforded, which gives with acids a rose coloration, the original tint being restored by alkali. These coloured seeds yield from 10 to 15 per cent. less oil, and are far below the market value of genuine colza seeds.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Comestibles.—A popular French term for victuals, provisions, eatables, etc., particularly those luxuries sold by grocers for human alimentation.

Comestible Oils.—See *Edible Oils.*

Commanderia Wine.—A sort of sherry, very popular in Cyprus.

Comfits.—F., *Petites dragées* (also known as *Scotch Carvie, Carvie Comfits, Hundreds and Thousands*, etc.).

These minute confections are usually made in revolving vacuum pans heated by steam. A few carraway, anise, or other small seeds, after being well cleaned and dried, are thrown into the pan, and upon these is carefully dribbled a little syrup of white sugar, which dries upon and coats each seed. By further additions these coated seeds not only increase in size, but retain their original shape. In this way the minute globules known as hundreds and thousands are made. If the goods are required to be white pure sugar is employed to pour into the pans. But suitable colours—such as pink, blue, green, brown, silvery grey, etc.—and essences can be added to the sugar as required. If these minute globules were allowed to remain for a longer time, new material being constantly added, they would gradually increase in size to the diameter of large marbles. The shape of the comfit is determined by the shape of the centre. For instance, if almonds are put in the pan the re-

sulting goods are almond shaped, the nut forming the interior. In this way a variety of shapes are obtained, but all more or less rounded owing to the rotatory movements of the pans.

The goods, when finished, are dried, sorted, and are then ready for glazing. The latter is accomplished by placing the sweets in a cold revolving pan containing the glazing material. (See *Dragées.*)

Composite Candles. — A name given to mould candles when made of tallow, from which the greasiness or oleic acid has been extracted, and the stearic and palmatic acids only remain, forming a hard crystalline composition.

These were first introduced in 1840 by Price's Candle Company, for the purpose of the general illumination on the occasion of Queen Victoria's marriage, and as a cheap candle which should require no snuffing, and were made from a mixture of stearic acid and cocoanut stearine.

Compote.— A French name for stewed fruits or vegetables, etc. A ragout of pigeons or small birds, also fruits dressed with a demiglaze of sugar, as *Compote de Fruits* (stewed fruit), *Compote de Pigeons* (stewed pigeons).

Compounds are admixtures, the term "compound" being often used instead of "adulteration," as with mustard, etc. Great care is necessary not to supply compounds when the article itself, as "mustard" simply, is asked for.

Compressed Flowers.—Tablets of pure sugar flavoured with various perfumes are sold under this name. (See also *Preserved Flowers.*)

Compressed Julienne. — See *Julienne.*

Compressed Tea. — See *Brick, Tile, Puèrh,* and *Tablet Teas.*

Compressed Vegetables.— Vegetables have for ages been known to be an indispensable food for humanity.

In the days of the Pharaohs in Egypt, it was customary to gather vegetables and preserve them, by drying them either in the sun or in ovens, and that simple custom prevailed with little alteration down to 1846.

In that year a Monsieur Masson, head gardener to Louis Philippe, King of the French, invented a process by which vegetables, herbs, and fruits could be dried by hot air in such a way as to retain all their flavour and good properties for several years, and yet occupy only one-eighth of their original bulk. It was not, however, till 1854-5, the date of the Crimean War, when thousands of British and French soldiers and sailors died of dreadful diseases through lack of vegetable food, that the full value of M. Masson's invention was realised.

The allied Governments of France and England at once ordered vast quantities of these dried vegetables to be prepared and shipped for the troops, but the great bulk necessary for so many thousands of men would have made it very difficult to execute this order had not Mr. Chollet, in conjunction with M. Masson, invented a mode of compressing the dried vegetables into cakes or slabs of such small size that they actually succeeded in compressing sufficient vegetables for one ration for 40,000 men into the space of one cubic yard!

Since that memorable time Messrs. C. Prevet & Co. (successors to Messrs. Chollet & Co.) have introduced many improvements into the manufacture of these Dried and Compressed Vegetables. They have been largely used in all campaigns all over the world, down to the late Nile, Soudan, Burmah, and Chin-Lushai expeditions, and our Board of Trade have (by Circular 696 A) enjoined that all sea-going vessels carry *Chollet's Compressed Vegetables*, as a medical necessary and a preventive of scurvy. In fact, they seem to be an indispensable article of provision at sea, on the march, in the camp, and in the bush. All Arctic expeditions have used them, and they are specially suitable for boating, sporting, and survey parties.

The actual proportions and kinds of vegetables employed by Messrs. Prevet are, of course, trade secrets, but they are only gathered in the autumn when in

their prime; first carefully sorted and washed, peeled, and cut into strips by machinery. Next they are slightly steamed and dried in iron cupboards by currents of hot air, each kind of vegetable separately, so as to fix the saccharine and albuminous properties and prevent the waste of essential oil. Afterwards the vegetables and herbs are mixed in the proper proportions, and compressed by powerful hydraulic machines into slabs, about ¾ inch thick, and same time divided by grooves into five-ratio squares or cakes. These squares are then wrapped in paper and sealed up in air-tight tins, the lids of which bear the date of manufacture embossed from the inside.

Vegetables, fruits, and herbs are also prepared and put up separately without being pressed into cakes. There is a great demand for special kinds, as, for instance — in Africa, for *celery*, as a cure, when stewed, for rheumatism caused by sleeping on the open veldt; in India, for *onions* to make a soup, considered a sovereign antidote for over indulgence in spirituous liquors; also in the Hudson Bay Territory for warming the stomach; while in Burmah, compressed apples and pears are mainly sought after.

Several other manufacturers have from time to time endeavoured to compete with Messrs. Prevet, but at all the International Exhibitions since 1851, this firm have been awarded first prize medals.

Their London Depôt is at 134 Fenchurch Street, E.C., and their proudest title is that bestowed on them by British bluejackets and soldiers after the Soudan War—"Jack and Tommy's Friends."

Comptie. — An American name for the bread-root of the Indians, a species of cassava, and grows well in Florida.

Conatto.— A rich liqueur imported from Australia. It seems to have the flavour of curacao and rum shrub combined.

Condensed Milk. —F. *Lait Condensé.* (Also known as *Preserved Milk, Swiss Milk*, etc.)

Condensed Milk is milk boiled down or evaporated in closed or vacuum pans until more or less of the water goes off in the form of steam, large air-pumps being also generally used to pump the air out of the covered pans in which it is boiled, and thus it is made very quickly, so that within twelve hours of being drawn from the cow it is usually condensed, cooled, and ready for tinning. There are many qualities; in some cases very little water is taken away, in others all or part of the cream is skimmed off, or otherwise extracted from the milk before it is boiled. The best is made from pure new milk, with all its cream as drawn from the cow.

It is first refrigerated, then boiled or evaporated to about one-sixth its original bulk, either with or without the addition of a little refined cane sugar, and is finally cooled and put into tins and hermetically sealed, when it will keep good for a long time.

When wanted for use the tin may be opened, the contents again diluted with five or six parts of water, and it thus becomes normal milk again, the sweetened kinds being, of course, milk with sugar, but with all the nutritive elements originally contained in the fresh milk, and in an unchanged condition.

As already stated, it may be prepared either with sugar or without; but if required for long keeping 40 to 60 per cent. of sugar is added, whereas the unsweetened will only keep good for a week or ten days, and only a few hours when opened.

The latter, however, is often preferred, and if mixed with three or four times its bulk of water, and set in shallow dishes for ten or twelve hours, a cream will rise, which, if churned at a temperature of 70° F., will produce butter, thus showing clearly that the butter globules are retained and unbroken.

Its history.—M. Appert was the first to recommend that milk should be boiled down to about *one-half* its volume before putting it into bottles, and in 1846 Bekaert tried to improve the process by adding carbonate of soda to the milk, but it is said the credit of first condensing, or rather concentrating, milk to about *one-sixth* its bulk is due to a Frenchman named Martin De Leignac, about 1847, from whom the process was

obtained soon afterwards by Mr. E. D. Moore, a doctor attached to the English Court, and who had manufactories in Staffordshire and Middlesex, making concentrated milk, and also a combination of cocoa and milk.

In 1857 Mr. Moore retired from the business, which, however, was taken up by his manager, Mr. House, and on an "improved patent," and has been carried on mostly in the shipping trade.

In was from Mr. House (through a Captain Fletcher) that Mr. Gail Borden, of White Plains, New York, the great milk condenser in America, got the idea; with this difference, that Mr. House's "concentrated" milk was got by evaporation of the water in *open pans*, and Mr. Borden's by evaporation in *closed "vacuum" pans*. Borden's product was put on the American market about the year 1860; but it was not till 1867 that condensed milk, as we now know it, was introduced to the British public.

This latter process, with perhaps some improvement on it, was (in 1866) adopted by some American gentlemen, who established the Anglo-Swiss Company, at Cham, in the Canton of Zug, Switzerland. The Aylesbury Company (established 1870) was an offshoot, or rather secession, from the Anglo-Swiss.

Preserved or *desiccated milk*, in the form of *a white powder*, was, however, prepared (for ship's use and export) both in England and on the Continent for many years previously; but that process broke the butter globules, and seriously changed the character of the milk. It could only be dissolved in warm water, and went out of use soon after the "condensed" article came into competition.

Fresh cow's milk is probably preferable to any preserved milks, but the convenience of the condensed article to travellers, voyagers, and sailors is very great. Other advantages are it is pure and of uniform quality; being condensed near where it is produced, it receives no injury in transportation; it does not change, but keeps good any length of time; special care is necessarily taken at the factories to obtain fresh milk from the farmers, not only of good quality, but in good condition; it cannot be tampered with after preparation and the tins hermetically sealed; and it is convenient and always at hand at any hour of the day or night.

The larger milk factories receive the produce of 2,000 to 3,000 cows daily, hence they are established in those grazing centres where a plentiful supply of the fresh fluid can be depended upon, and at a low contract price—say 4d. to 8d. a gallon; or, if by weight, so much per 100lbs.

Some of the leading companies employ their own inspectors, and will not take milk from a farmer who feeds his cows on ensilage, turnips, brewers' grains, or on cabbage; neither will they take any milk within sixty days of cow calving, nor within six days after calving.

It should be mentioned that the greatest cleanliness is observed throughout the whole process. Even the milk tins which the farmers deliver, immediately on their being emptied, are, in the receiving room, placed in warm water and scrubbed inside with brushes. A strong jet of steam is then turned into them, searching every chink and cranny; and, finally, another very powerful jet of cold water completes the cleansing process, which is also applied continually to all cylinders and receptacles used in the factory.

The milk received from the farmers is tested in a variety of ways several times in the week; and some is stood in pans to test the rise of cream, a record of which is carefully kept. The contracts with the farmers are very stringent, and if anything is found wrong with the milk the company reserve to themselves the right of returning it, and at once throwing up the contract.

They are careful also to examine the police records of the district, to see if any of the farmers whose milk they

take have any cases of diseased cattle on their farms, which they are bound by Act of Parliament, under heavy penalties, to report at once to the police.

The sugar used is of the best refined kind, some also from beetroot, and we need hardly observe that no adulteration takes place at any part of the process; it would be impossible, and, if attempted, would at once defeat the great object—namely, the preservation of the milk. Thus we have an article which is pure milk—not an article made from milk—with the addition of sugar, all that is taken from the milk being the water, which, in milk direct from the cow, constitutes as much as 80 parts out of 100. Astounding as this statement may seem, there is no doubt about it, and the stream of colourless water which runs freely and continuously from the condensers gives ocular evidence of it; and its being almost tasteless further shows that by the process the milk loses nothing but its water, and this it does to the extent of about 55 parts out of the 80—leaving in the condensed milk from 20 to 25 parts of water, the rest being the caseine, butturous, or fat, and other solid substances which remain intact. This is proved by the fact that when the proper quantity of water is again added to the condensed milk, it will, at a certain temperature, churn into butter.

Danish Tinned Milk.—It has long been the aim of scientific effort to produce condensed milk which in taste, smell, nutritive value, and easy digestive qualities would replace fresh milk. By a simple and ingenious process, carried out by Mr. Fjelstrup, the Danish milk is condensed at a low temperature in such a manner that its chemical composition is unaltered, and at the same time all bacteria are destroyed. This condensed milk is without any addition of sugar or other foreign substance, prepared from the best milk, obtained from cows under the constant inspection of veterinary surgeons to guard against the transfer of contagious diseases of which milk may often be the bearer. Condensed to about one-third of the original volume, it may in this state serve the purpose of ordinary cream, and mixed with two parts of water to one of condensed milk replace the original pure milk. The principal object is, however, to provide an article of export, packed in hermetically closed tins, that durability may be secured for an indefinite length of time, and for use in tropical climates where there is no opportunity of securing fresh milk, and this object has been fully achieved. The milk having undergone the necessary process in the condensing vats is tapped by the method patented by the factory, into sterilised tins, which are closed air-tight, as they run full, one by one, and then soldered immediately. These tins are placed in rows on shelves, where they remain for some time under close observation, until they are packed for exportation in cases containing four dozen each. The tins are fitted with tubes, the cutting of which enables the milk to be drawn in a clean and convenient manner. After a portion of the milk has been taken out the tubes prevent the exposure of the milk to the air, and by this means the product retains its freshness and purity for a long period.

All good things, however, are subject to base or inferior imitations. The convenience and cheapness of condensed milk, and its supposed better keeping properties, have led to its very wide use, in spite of the serious drawbacks to its use as a staple article of food for infants. That even the best brands often do great harm by interfering with proper nutrition, and favouring the development of rickets and scurvey, is well established. And this being true of brands that are prepared by the concentration of cows' milk of good quality, it may be imagined that a much more serious indictment could be

brought against some inferior kinds in the market. The mysteries of composition of these have not yet been satisfactorily revealed, but it is known that skimmed or separated milk is by no means the only ingredient. A vegetable article is being largely imported, and being bought by certain milk manufacturers for the purpose of adulterating their wares. The adulterant is known commercially as the "Tiger Nut," and has the appearance of a rhizome, is no larger than the last joint of the little finger, and resembles a diminutive root artichoke. It is not unpleasant to taste, the flavour being strongly suggestive of condensed milk. It is possible that in this ingredient we have the explanation of some cases of condensed milk wasting and dyspepsia. Glucose, also, is used in several of the cheaper brands. The directions given on the labels for diluting the product with water would, if followed, result in producing exceedingly weak liquids of very little value, and to use such preparations as the sole food for infants would undoubtedly be seriously injurious to their health.

The labels on these spurious brands are evidently intended to mislead. It is a pity firms are permitted thus to label stuff, not merely "partially skimmed" or "skimmed," but made from milk from which the nutrition has been removed with a completeness only practicable by the employment of centrifugal separators.

"Separated" milk is, of course, much inferior to milk which has been merely "skimmed," but in order that the purchaser shall not be defrauded, and human life sacrificed, it is now enacted under a smart penalty that "condensed milk from which any of the cream has been removed must be conspicuously labelled 'machine separated milk' in large and legible type, and on labels pertaining to this article the word 'milk' must not be used unless preceded by the words 'machine separated' in equally bold type."

Complaints are also frequently made of short weight in the tins of some makers.

A 1lb. tin should weigh 18¼ ozs., or 18½ gross, and a few brands may scale more, but a great number are short of this weight.

Apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Condiments.—W. *Sibra.*

A name for seasoning and flavouring substances, such as salt, vinegar, sauces, lemon-juice, spices, herbs, eating-oils, butter, sugar, honey, pickles, sausages, etc., to render foods more palatable, wholesome, or digestible, and particularly a term for those substances which are intended to stimulate jaded appetites.

They are credited with promoting digestion, but their hygienic action is not yet clearly understood, and in some persons their use may be very injurious.

Condiments are really adjuncts to and accessories of food rather than foods, and although there once existed among the faculty a certain amount of prejudice against all condiments except salt, they have long been used by the oldest civilised nations, and in this country there now seems to be a general consensus of dietists in their favour. Their excessive use, however, is said to vitiate the gastric juice and injure the stomach.

The word "condiment" has its restricted and more general application, signifying in the first place the *compound* of which sauces, curries, chutneys, etc., are the representatives, and in the second place all substances used as "food accessories," for the purpose of stimulating and pleasing the palate.

In this latter sense it covers the large family of spices, edible oils, olives, capers, salad plants, including onions and their congeners, mushrooms, truffles, caviare, and even "sweets," such as sugar, honey, and preserved fruits, and last, but not least, mineral salt.

All these have been classed as "condiments" by various authorities.

Gardner's patent "Rapid" sifter and mixer, freely used for above. Prices from 50s. to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Cones.—A mixture of bad or slightly damaged flour, heavily alumed, and often used by bakers in bread making. The alum improves the colour, but its use is illegal.

Confectionery.—Sugar, when good, is almost the most valuable thing which enters the mouth of man, woman, or child. (See *Sweets*, *Boiled Sugars*, etc.)

There is scarcely any other equally important feeder of muscle power. The labourer can do nothing better than keep a few lumps of sugar in his pocket. The negroes in sugar plantations renew and quicken their weary bodies by sucking the sugar canes. Sugar is a fine restorative for soldiers. A Dutch Army surgeon asserts that during an expedition in Sumatra he found that the best means to maintain the soldiers in vigour and freshness, not only during the march, but during the fight, was a generous allowance of sugar. Each man was served with a handful at a time. The Swiss chamois hunters bear similar evidence to its marvellous powers of sustenance and of recuperation after exhaustive fatigue.

A writer in *Kuhlow's* gives an account of successful experiments made with sugar as food for athletes by several of the Dutch rowing clubs, by pedestrians, by cyclists, and others whose bodily powers need "a rapid, portable, and innocent stimulant." Sugar is coming more and more into use in the course of "training" for contests, and it is as good for beasts as it is for men. The poor hardly realise as yet, or only realise unconsciously, what a treasure they possess in cheap sugar. Its value in fever has been emphasised by Hupeland and others. That which is supposed to injure the teeth in the consumption of "goodies" is not the sugar, but the so-called "fruit acids" which are introduced to flavour the sugar. Negroes who devour sugar in so huge a quantity, have the best teeth in the world.

For all kinds of confectionery apply to the Compagnie Francaise, London Works, Bermondsey New Road, London, S.E.

Confectioner's, Icing, and Caster Sugars.—These are supposed to be highly refined sugars ground to powder in fast-speeding steel mills; but, like all powdered sugar, should always be looked upon suspiciously, being capable of containing low qualities and adulterants.

In well-appointed English factories the sugar mill is a closed chamber, consisting of several compartments, bearing a number of blades on an axle, and a fan. The blades move at the enormous speed of 2,500 revolutions per minute. The sugar is fed into a hopper, and slowly passes to the disintegrating chamber. Here it is subjected to a fearful pounding, and speedily reduced to a fine powder. The reduced sugar is now blown by the fan through a delivery tube to a revolving sieve, through which it is sifted in appropriate bins according to the size of the granules, ready for use in the different departments of the Confectioner.

Icing Sugar is that which is ground to a very fine, impalpable powder, resembling flour, and should consist of pure cane sugar; for beet sugar, although white enough to look at, is not capable of high crystallisation, and turns a red colour if highly heated, thus spoiling the appearance of some goods.

Caster Sugar is a coarser grade, and may be either specially ground or merely the sifted dust of lump sugar.

Tinted Sugars (or coloured sugars). Names given to the above sugars when artificially coloured blue, red, green, pink, etc., for use in fancy cookery and confectionery. A few pounds of sugar are put in a bright copper pan and gradually heated over a fire while being stirred by the hand. When hot, a little liquid colour (often aniline dyes in solution) is sprinkled over it, and the whole

is again well stirred till quite dry, and the desired shade obtained.

These finely granulated sugars are often made up of the re-refined refuse of high-class sugars, and should only be used as dry powder, not melted.

Confectionery Varnish.—A nice varnish for all kinds of chocolate work and candies—pulled and clear.

The varnish is perfectly harmless and very fragrant, resembling somewhat the flavour of vanilla.

To prepare it, take ½lb. or more of gum benzoin, put it into a bottle, and cover it with finest proof alcohol, cork up tightly, and let it digest for at least two weeks, shaking up once or twice a day, after which time pour off any portion required for immediate use.

It should be the thickness of thin syrup; if too thick, dilute it with alcohol. It will keep and improve for years, and forms when dry a thin glossy film or skin over the goods, which prevents the access of moisture and keeps them from becoming sticky.

Confiture d'Apte. — See *Crystallised Fruits.*

Congou. — A generic name for the teas exported from Hankow, in China.

The word *Congou* itself is a corruption of the Chinese term *Kung-fu* (labour), referring to the labour or work required in manipulating this sort. The tea is a common quality of black, but a grade above Bohea, with larger leaf, not so dusty, and is the chief sort imported into England from China. The Congous grown in the north of Amoy are of superior quality, and probably the best come from Ningchow, although also furnished by Hu-Kuang and Ho-Nan. The best black teas of Fukien are also designated by the generic terms of Congou and Souchong. These come from the districts of Tenmon, Kaisu, Seng-Cheng, Cheng-Lock, Pan-Yang, You-Kai, Pack-Long, Pack-Ling, etc.

Moning Congou is a sort of the same tea produced at Wuning, a district and city, the name of which means "military rest."

Packages. — Chests average about 106lbs., half-chests 61lbs. and 20lbs.

Congreve's Balsamic Elixir.—(See also *Patent Medicines.*)—This has been analysed on different occasions, and declared to be a mere infusion of elderberries, alcohol, benzoic acid, and allspice.

Consolidated Soup. — See *Erbswürst.*

Consomme (pr. cong-smay). — A French name for clear soup, or the "stock," or gravy obtained by simmering or stewing meat, bones, poultry, vegetables, etc., and afterwards straining and clarifying the liquor. It is really a "Liquid Extract of Meat," and called "Consommé" because it represents meats wholly exhausted or consumed by the prolonged cooking. "Potage" is the French term for a *thick* soup.

Constantia Wines.—Three kinds of delicate and luscious wines—both red and white—produced in the district around the town of Constantia, in Cape Colony, South Africa.

These wines have been held in high repute for over a century, and called after the name of the Dutch Governor Van der Stell. They are high priced, but their sale in England has greatly diminished.

Cooking Oil. — See *Edible Oils.*

Coombs' Eureka Aerated Flour. —See *Aërated Flour.*

Cooper. —See *Porter* and *Stout.*

Coorg Coffee.—A rather coarse and strong variety of East Indian coffee. It, however, produces a beverage of fine colour and not unpleasant flavour.

In his "Manual of Coorg" the Rev. J. Richter gives a very interesting description of its cultivation.

Copal. — A commercial name for resinous varnish or semi-fossil gums, generally found buried at various depths in the neighbourhood of gum-yielding trees, or on the site of extinct forests. Most of them come from East Indies, Brazil, West Africa, and New Zealand. (See *Kauri Gum.*)

Copperas. — F. *Couperose;* G. *Kupfervitriol;* Sp. *Caparrosa.* (See *Vitriol.*)

Copra, Copprah, or **Copperah.**—F. *Coprah;* G. *Copranusse;* It. *Noci ai Copra;* Sp. *Nueces de Copra.* (See also *Coker-nuts.*)

The dry and hardened pulp or white kernel of the milky cocoa, or coker nut (*Cocos nucifera*). Copra mostly comes from South Sea Islands, Samoa, Guiana, Cochin, and Ceylon, and its production at best is rather a slow and laborious process; but it forms the single exportable staple of Samoa, and is the one upon which all its business at present rests. The trees are there planted in rows, 40 feet apart, and the trees of each row 30 feet apart.

The trees come into bearing about the sixth year, and the crop increases for 20 or 30 years. The gathering and curing are effected as the nuts ripen, from about the middle of April till the end of October (the dry season). A man or boy with a piece of "sennet" about 18 inches in length, looped on each foot, will climb the slender, swaying tree with as much ease and rapidity as if it were a ladder. The notches or corrugated surface of the bark catches the bit of sennet between the feet, while the weight of the body, pressing downwards, clamps as it were the hollow of the feet firmly on either side of the trunk. By this means, the tree is ascended by a series of jumps, and the climber, with a big knife, cuts away the matured nuts, which cluster close about the butts of the branches. As they fall they are carried into piles. The nuts are not husked, the thick outer husk having become hard and brown, like wood. They are dexterously split in two by an axe, and the hard, white flesh is cut out with a large knife, and spread on mats or boards in the sun till sufficiently dried and cured for shipment. It takes about 8,000 nuts to make a ton of copra. Samoa exports about 5,000 tons of copra yearly, and in the trading stations on the coast enormous profits are made in the trade. There is an interesting British coker-nut plantation at Faleula, about five miles from Apia, in Samoa. It consists of 65 acres.

Another at Lata, on the island of Savaii, of about 225 acres, produces coker-nuts, yielding about 5 cwts. of copra per acre. The best crops yield about half a ton of copra per acre. Suitable "flat-bush" land for growing in the islands of that region varies from 4/- to 24/- per acre, while the price for land in full bearing is £5 to £12 per acre, according to accessibility.

The ordinary method adopted in some of the islands of the South Pacific by the natives for liberating the nut from the shell, is to break the latter into two or more pieces by blows from a hammer, and to leave these exposed to the sun's rays for a few days, when the kernel or pulp contracts into a hard horny substance, and leaves the shell without trouble. Copra is chiefly imported for the expression of *coker-nut oil*, of which it contains 62 to 65 per cent., and which is ordinarily obtained by first soaking the copra in water, and afterwards subjecting it to two pressings. Copra oil is found to be the best ingredient for white soap. The nuts yield the best oil when ripe; but if any of them be gathered too early, the oil is both impure and of bad colour, and will spoil the better oil if mixed with it.

A considerable quantity is now exported from Pemba Island. Pemba copra is generally black, this is because the cultivators, in their haste to sell, do not allow it time enough in the sun, but dry it by fire heat. It requires seven days' hot sun to thoroughly dry it, and as the weather is often wet, a fire is made of the nut-shells, and these give out a dense smoke, which blackens the nuts. Two days of this drying or smoking is sufficient. The kernel is then extracted from the shell, and is ready for export. Cochin copra is the finest.

Copying Ink.—(See also *Writing Inks.*)—This is easily prepared by mixing together eight parts (by weight) of

ordinary ink, three parts of candied or twice refined sugar, and one part of pure glycerine.

Coralline Pepper.—A fancy name given to ground chillies of high, bright red colour.

Cordage.—Port. and Sp. *Cordelaje*; W. *Rhaffau.*

The general name for ropes, cords, and twines. Manilla hemp and Sisal hemp, from Yucatan, are considered the best and strongest material for producing good quality.

A *rope* is properly a stout, twisted cord, usually more than an inch round, and made of hemp; when smaller it is called *cord.*

Coir ropes are made from the fibrous husk of the cocoa (coker) nut. They are fairly strong, and much lighter than Sisal hemp or manilla, also better able to resist the action of water, but are rough, and never tarred for preservation.

Tarred ropes are more durable, but not so strong, as the untarred, and are liable to be injured by the impurities in the tar.

Wire ropes, first made in 1833, are not so flexible as the above, but are thinner, lighter, and less bulky, and, not being affected by moisture, or dryness, are the most durable of all.

Italian cord is made from a remarkably fine variety of hemp, raised by spade culture, and known as Italian garden hemp.

Glazed box-cord is a regular article of retail trade, value 20/- to 30/- per cwt.

Fine twines are usually described as of 2 or 3-ply, and as running so many yards to the pound. A *3-ply choice*, measuring 300 to 600 yards to the pound, is worth 5/9 to 6/9 the dozen lbs.; *3-ply Italian*, about 800 yards to the pound, is 8/- to 8/6 per dozen.

Apply to E. Fellows & Co., 7 and 9 Avonmouth Street, London, S.E.

Cordials.—(See also *Fruit Juices, Syrups*, etc.)—A name given to certain British-made liqueurs, or stimulating beverages, formed of weak spirits, aromatised and sweetened. (See also *Liqueurs.*)

The usual ingredients are rain or distilled water, clean spirit, and flavouring substances.

There are numerous kinds prepared, such as cherry brandy, clove, jargonelle, lime-juice, peppermint, pine-apple, quinine, raspberry, sarsaparilla, strawberry, &c.

Fruit Cordials have come prominently into use lately. When mixed with water they are supposed to form very agreeable beverages, but, unfortunately, many of them possess such a distinct flavour of the chemical substances used to preserve them that they become objectionable, although not unwholesome.

Cordillera Wax.—A product of the wax or varnish tree of the Cordilleras.

Coriander-seed.—F. *Coriandre*; G. *Koriander*; It. *Coriandro*; Sp. *Cilantro*; W. *Llysian y Bara.*

The dried seed, sometimes spelt coliander, of the umbelliferous plant *Coriandrum sativum*, an annual, nearly like parsley, and grows one to two feet high, but has a rather nasty smell. It is native of the South of Europe, much grown in Italy and France, but is also cultivated in Essex and Suffolk, and in several other countries. Large quantities arrive from India. The seeds are round, slightly ribbed or ridged, very light, of a yellowish brown or straw colour externally, nearly as large as peppercorns, and inside the husk each seed consists of two closely-fitting hemispherical mericarps. These seeds have a mild aromatic and pleasant taste when dried and bruised; but when fresh both the seed and the plant emit a rather disagreeable odour.

Corianders and caraways are frequently sown together, the corianders bearing the first year and the caraways the year following.

Coriander-seed is chiefly used by distillers in flavouring gin, and in making

a cordial. It is also used in confectionery and medicines, and occasionally in mixing curry-powder. It covers the taste of senna better than any other substance.

Corigliano Juice.—A superior and well-known brand of liquorice-juice, made in thick sticks at the Italian hill-side town of Corigliano, in the province of Cosenza, near the Gulf of Taranto.

Corinthian Raisins. — See *Zante Currants.*

Corks.—F. *Bouchons*; G. *Tfropfen, Korken*; Port. *Rolhas*; It. *Puraccioli*; Sp. *Tapones, Corchos*; W. *Madarch.* (See also *Bungs, Shives*, etc.)—These are made from the thick and spongy bark of a species of evergreen oak, *Quercus suber*, growing about thirty feet high, in the dry, mountainous districts of Spain, Portugal, Southern France, Italy, and Barbary. Algeria also has vast forests owned by the State, especially in the department of Constantine. The trees in the district of Tell, being of hardy growth, are likely to become very important, and the State sales take place each autumn at Constantine and Algiers. The Spanish Peninsula, however, leads in the supply of corkwood, the trees not only growing wild, but have long been cultivated in forests.

The Spanish cork forests cover about 620,000 acres, the chief provinces being Gerona, 198,000 acres; Huelva, 134,000; Cáceres, 80,000; Sevilla, 74,000; Cadiz, 55,000; Ciudad Real, 28,000; Cordova, 23,000 acres. The forests of Gerona being near the coast, immense quantities are easily exported from there. The Catalonia district produces the best bark, compact and firm, while Estremadura and Andalusia yield cork of much quicker growth, but of inferior quality.

The cork oak sheds its bark periodically if left to itself, but the corkwood is much better if removed artificially, and this may be done without injuring the tree. The tree (called in Spain "*el alcornoque*") should not be barked till 25 or 30 years old, after which it may be done every eight or ten years till 150 years or more old.

The cork of the first barking is called *virgin cork*, but it is not fit for bottle corks. The older the tree the better the corkwood. The cork tree is liable to the attack of a voracious caterpillar—a pest sometimes appearing in millions in the cork tree forests, and in a very short time stripping the trees of every leaf.

Cork being light, porous, readily compressible, wonderfully elastic, and easily cut into any shape, makes it more suitable than any other substance for stoppers for jars, bottles, and other vessels, especially as, notwithstanding its porosity, it is nearly impervious to ordinary liquids.

The wood is also extensively used in making life-preservers and seine corks. When stripped from the tree it is boiled for two hours, cured in the sun for a week, and then pressed into flat pieces for baling and shipping. Before being made into corks the corkwood is charred on each side, which makes it contract and lessens its porosity, conserving the liquor without absorbing it and excluding the air. Immense quantities of corks are also made in the Gironde department of France for use in the Bordeaux vineyards. The bark is mostly grown in the departments of Var and Pyrénées Orientales, but some 8,000 tons of the wood are imported into France from Spain. One pound of cork can be made into 144 champagne corks. The annual export from Spain is over a thousand millions of corks, besides about 1,000 tons of corkwood in bales. (A bale weighs 160lbs.) Total value about a million sterling.

As already implied, Gerona is perhaps the most important centre of production, hundreds of factories being scattered over the whole province, the town of Palmos alone having forty. The chief cork factories in Portugal are in the provinces of Alemtejo and Algarve, but the cork tree grows nearly all over the country, excepting the extreme south.

Large quantities of corks are now cut both by hand and machinery in London, Liverpool, etc., from bales of the imported cork-wood.

"*Daffies*" are the small corks used by chemists 1 to 1½ inch in length, and are usually divided into four qualities—superfine, fine, seconds, and thirds, varying in price from 6d. to 2/- per gross.

"*Vials*" are similar corks, but of smaller size, for vials of ½ oz. to 8 ozs., running from 4d. to 1/2 per gross.

Old Corks and Waste Corkwood.—Granulated cork, heated and mixed with mineral asphalte, and compressed into bricks, makes a very useful pavement, and is exceedingly durable; it is also quite noiseless, possessing great elasticity, and saves much wear and tear to the feet and legs by unyielding asphalte, granite, board, or brick floors, etc.

"Phellosene" is the name given by a French inventor to the substance he describes as artificial cork, and which may be used for all purposes for which cork has hitherto been found needful. It is an analogue of celluloid, and consists of cork bark ground to an impalpable powder and agglutinated by a solution of nitro-cellulose in acetone. This material is made into a doughy mass, compressed into moulds and dried. It contains about 10 to 12 per cent. of nitro-cellulose, and is said to be a trifle, if anything, more combustible than cork under the ordinary conditions.

For best Corking Machines, apply to Parnall & Sons, Ltd. (See adv., page 9.)

Corn—F. *Grain;* Port. *Cereaes;* Sp. *Cereales;* W. *Grawn.* (See also *Indian Corn.*)

An old Anglo-Saxon term for all kinds of grain, especially the seeds of certain grasses used as food; those mostly used by mankind—such as wheat, rye, oats, barley, maize, rice, and millet—being known as bread-corn or bread-stuffs, the latter term including flour and meal as well as grain.

Corn Balls.—(See also *Pop Corn.*)—Red and white edible balls made of *popped corn,* cemented together with white of egg or other similar substance, and sweetened with syrup or sugar.

Corn-Bread.—See *Maize-Bread.*

Corn Flour.—(See also *Maize.*)—This is not exactly the flour of Indian corn (*Zea Mays*) or rice, but the name given by Brown & Polson to an article of food made by them from maize by a special process. Since its introduction various improvements in the manufacture have been effected by them, until at the present day what is known as "Brown & Polson's" Corn Flour—of which "Patent" is their best brand—is, par excellence, the standard for purity, strength and flavour.

This delicate powder is prepared by an elaborate roasting and washing process, and without fermentation.

The numerous amylaceous preparations sold as Corn Flour, Maizena, etc., are mostly produced in imitation of Brown & Polson's. One kind, known as British Corn Flour, is said to be made from rice. They consist principally of starch, and are all intended for the formation of custards, blanc-mange, puddings, pancakes, and other palatable concoctions; but very few are at all nutritious, and some have proved fatally deficient in several instances where young children have been chiefly fed on them.

It is true Indian corn well ground contains about 11 per cent. of nitrogenous or flesh-forming nutriment, and is therefore a substantive food of the highest class; but many of these prepared Corn Flours contain only 13 to 33 grains out of a pound of such flesh-forming nutriment, instead of the 800 or 900 grains in Indian corn itself; or, in other words, the greater portion is often abstracted by soda or lime during manufacture, and only about 2 per cent. left.

In Corn Flours everything depends on *quality*, for although there are makes at about half the price of Brown & Polson's *Patent*, this brand has the largest and easiest sale of any.

The factory was started at Paisley; and a remarkable illustration of the plant-like propagation of trades and manufactures is presented by the fact that until very lately all the factories engaged in the corn flour business were within a radius of seven miles from their works.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Other Special Firms.—M. E. Holdsworth, 3 Norfolk Street, Bradford; John May, 114 Church Street, Croydon; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Corn Grits or Samp. — See *Hominy.*

Corn or Maize Oil.—A new product from Indian corn, consisting of a yellow liquid much resembling linseed oil, but cheaper and in every way superior. It is used in preparing paints, varnishes, and soaps, both hard and soft.

The oil is contained in the germinal part of the grain, and amounts to about 4 per cent. of the whole grain. In the process of manufacture the germ is separated from the kernel, and the oil obtained by hydraulic pressure. Unlike linseed oil, it does not lose its clearness when subjected to the cold.

This oil was until recently a waste product which was lost in the ordinary method of making starch and glucose.

A Chicago glucose company is reported to be making over 1,000 barrels of it daily.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Corn Starch Sugar.—(Also known as *New Process Sugar.*)—An American mixture of Indian corn starch with cane sugar.

It has never found a ready sale, on account of the difficulty of drying it; and the manufacture of this anhydrous substance has so far really proved a commercial failure.

Corn Sugar.—See *Glucose.*

Corned Beef. — (See also *Tinned Beef, Scotch Ham Beef, Beef à la Mode,* etc.)—Beef preserved and seasoned either with salt in grains or laid down in brine.

Recipe:—To each gallon of water add 1½lbs. salt, ½lb. sugar, ½ oz. saltpetre, and ½ oz. potash. Boil and skim, and when cold pour over the meat.

Another:—Put the beef into a deep earthenware pan that will just nicely hold it, and cover it entirely with a pickle made in the following proportions: 1lb. of bay salt, 6 ozs. of common salt, 1 oz. of saltpetre, 2 ozs. of salt prunella, ½lb. of brown sugar, and 1 gallon of water. Boil these ingredients for 20 minutes, then skim carefully, strain, and use when cold. This pickle can be used over and over again if, after each time of using it, it is reboiled with the addition of a little more salt.

Corned Beef is also imported in tins of 2, 4, 6, and 14lbs., in a cooked condition.

Cornish Pilchards.—See *Pilchards, Sardines,* etc.

Corsican Wines. — See *French Wines.*

Cosaques, Crackers, etc.—Bright coloured paper bags, each containing one or two sweets and a surprise, such as paper slip with motto, or caps, costumes, etc., cut out in tissue paper of various colours. They used to be called Bonbons, and are very popular with young people at Christmas parties, balls, fêtes, etc.

Cosher Foods.—See *Kosher.*

Cosmoline.—See *Vaseline.*

Costa Rica Coffee. — This is a large and bold growth, colour bluish green, and giving a strong and useful, but somewhat coarse, liquor.

Cottage Cheese.—(Also known as *Smear-Case* or *Pot-Cheese.*)—A preparation of pressed curds, made without rennet, and served with salt or with sugar and cream.

Cottenham Cheese.—A new-milk cheese produced around Cottenham, near Cambridge.

It has a peculiarly fine flavour and consistency, not unlike Stilton in taste and appearance, but flatter and broader in shape.

Cotton-seed Cake.—F.. *Tourteau de Coton.* (See also *Oil Cakes.*)

A nutritious food for feeding cattle, and particularly for sheep. Cotton seeds as oil seeds were first imported in 1847; but the value of the "*Cake*" was only discovered about 1860. It consists of the husks and refuse of the seeds of the cotton-plant, *Gossypium,* pressed into flat cakes, after they have been ground and more or less of the oil has been extracted. The seeds weigh about twice

as much as the cotton itself, and the "hulls," which comprise 48 per cent. of the weight of the seed, are the most valuable part. In a loose and dry condition they form a perfect cattle food, and if mixed with a little meal are remarkably fattening. Hulls are sold in the United States at 3 to 10 dollars a ton, which is far below their intrinsic value, and most of the Chicago and Kansas dressed beef is really produced from cattle fed on cotton-seed hulls. Ninety per cent. of the value of these hulls is available for fertilisers, after being used as food, and *Cotton-seed bran* is a still more nutritious product. The seed itself contains casein, 6 per cent.; dextrin, 2; sugar, 2; febrin, 23·7; woody fibre, 32·1; starch, 9·6; greenish-yellow oil, 9·6; yellow wax, 0·8; water, 8·0; ash, 8·0; and it yields by grinding 56·5 per cent. of a yellow meal, which may be also used with milk in bread-making. Egyptian cotton, as well as the "Sea Island," or "long-staple" cotton (*Gossypium barbadense*), have naked seed, while the "upland," or "short-staple" cotton (*G. herbaceum*) of the United States and Brazil, has the seeds encased in a mass of fibre or lint firmly fixed to the seed-coat.

The cotton-seed crushed in England is mostly Egyptian, in fact, about 90 per cent. of the cotton seed imported is from Egypt, and about half of this is received and crushed at Hull, but in the United States and Brazil the chief seed used is the "upland," as the Sea Island cotton only grows over a very limited area.

The upland seed has therefore to be first delinted, cleaned, or decorticated, and this entails considerable expense and waste, while the Egyptian and Sea Island seed needs only to be crushed, heated, and pressed. New Egyptian seed usually reaches England from Alexandria end of January or early in February. The fluffy American seed will not stand storage nor exportation well, because the moisture absorbed by the fibrous envelope creates fermentation, and, this being liable to cause internal irritation in some animals, scientific records in the Southern States of America preponderate against the use of Upland seed as food for sheep and dairy cattle.

Before 1887 there were only two methods of getting rid of the lint, one being a chemical process which destroyed the fibre, and the other a mechanical process which crushed the shell and extracted the kernel. In both the adhering lint was wasted, being destroyed by the former and rendered useless by the latter through being mixed with the broken shell. Inventions patented by Mr. J. Y. Thompson in 1887 and by Mr. M. Crawford in 1888 perfected a machine for preserving both seed and lint for commercial purposes. Until the invention of 1888 the lint never existed as an article of commerce, but it is now of great value, being used for the manufacture of gun cotton, cordite, and paper. Brazilian seed is bought for £3 10/- a ton, and after it has passed through this machine £5 15/- per ton is obtained for the cottonseed—nearly as much as for the Egyptian—and from £5 to £6 for the lint, there being a ready sale at Liverpool and elsewhere.

Cotton-seed Oil. — A sweet oil, colour pale straw to yellow when purified, while the crude unrefined oil is red. This oil, now a very important product, is extracted by powerful steam or hydraulic pressure from the boiled seeds, cleaned and decorticated, of the cotton tree above referred to.

In America, where immense quantities are produced, it is divided into four classes: crude, refined (of a pale orange colour), purified, and bleached.

Its extraction is a somewhat worrying occupation, for besides the trouble of a difficult and imperfect and rather wasteful decortication, the colouring matter and tannin present are a constant source of care.

But of all vegetable oils introduced during the past thirty years, that from cotton-seed has found the greatest favour, both in this country and abroad, owing to the many and still increasing uses to which it can be put. There are over 250 mills in the United States—27 of them in South Carolina. When highly refined it is regarded by many as a very wholesome and nutritious article

of diet, and far superior to hog's fat. Being only about half the price of good olive oil, it is extensively used in hotels and large establishments for best cooking purposes, such as frying, making bread and pastry, mixing with lard, and for other kitchen purposes. Physicians, however, in the Southern States of America testify strongly against its use as food, instancing the deadly effects of the meal on sheep and cattle.

Large quantities are used for adulterating olive oils and lard, while the lower qualities are used for making both hard and soft soaps, etc. The presence of cotton-seed oil in lard, etc., is best detected by nitrate of silver. It reduces the silver to a metallic state, and is the only oil that will do this. Cotton-seed oil is not strictly a drying oil, although it will act as such when mixed with boiled linseed oil, but when added to olive oil it behaves as a non-drying oil. It is unfit for lubricating purposes on account of its clogging properties, and it turns rancid so fast that it is of no use even for making margarine.

It is, however, an excellent oil for laying on new woodwork, tools, etc., and much better than coal oil, kerosene, or even linseed oil. It is rapidly absorbed, and does not gum nor sweat out in hot weather. The seed contains some 25 per cent. of oil, a ton of seed yielding about 76 gallons, and there are about 1,000lbs. of seed to every bale of cotton. Value of seed £5 to £6 a ton, and of the oil £18 to £21 per ton.

Apply to C. Windschuegl & Co., I Leadenhall Street, London, E.C.

Coulommiers Cheese.—(see also *Brie Cheese.*)

A soft kind of whole-milk cheese, about 6lbs. each and usually sold fresh, or at least within ten days of manufacture. In making this cheese the coagulation is protracted, and the ripening really takes place before the curd is ladled out into the forms.

Coumarin or **Coumarine.**—A natural perfume, originally discovered in the Tonquin or Tonka Bean (*Dipterix odorata*), and much employed for perfuming snuff, tobacco, etc.; also to give flavour to the Swiss cheese called Scabzieger. A like substance has also been found to exist in and to impart their well-known and agreeable odours to several of our most common European plants, especially to *Anthoxanthum odoratum*, the sweet-scented vernal grass to which we are in the habit of ascribing the fragrance of well-made hay.

It is easily extracted from the Tonka bean by alcohol, and by evaporating the alcoholic solution the Coumarin is obtained in a solid state.

It forms white brilliant needles of an agreeable aromatic odour. When heated it rises in vapour, and this vapour, when inhaled, acts powerfully upon the brain.

It consists of carbon 73·97, hydrogen 4·11, and oxygen 21·92, so that it is richer in oxygen than most other volatile oils. The same odour which gives flavour to the Tonka bean also exists in the Faham tea of the Mauritius (*Agrœcum fragrans*), in our common melilot trefoil (*Melilotus officinalis*), in the blue or Swiss melilot (*Melilotus caerulea*), in the common sweet woodruff (*Asperula odorata*).

Counter.—The *counting-board* in a shop. "Counter-caster" is used by Shakespeare as a term of contempt for a shopkeeper. "Counter-jumper" is the modern synonym.

Couscoussou.—See *Koskossoo.*

Cowberries.—See *Whortleberries.*

Cowheel.—See *Trotters*, etc.

Cowries.—F., *Cauries.*

Small shells brought from the Maldives, and certain other islands, which pass current for coin in some parts of India and on the East Coast of Africa. Their value is about 1-130th of a penny. Spices and other grocery products are often bought from the natives and paid for in these shells.

Cowslip Hyson.—See *Hyson.*

Cowslip Tea (also known as Pagle or Paigle Tea).—An infusion obtained

from the dried flowers of the cowslip, *Primula veris*, said to have narcotic properties.

Cowslip Wine.—(See also *British Wines.*)—A wine generally made by fermenting cowslips with sugar, and used as a domestic soporific.

Crab-apples.— See *Siberian Crabs.*

Cracker Biscuits.—See *American Crackers.*

Cracknel Biscuits or **Cup Cracknels.**— Very light, puffy, and brittle biscuits, with peculiar smooth and shiny surface, made from paste that has been boiled before baking. They have a dry powdery taste, reminding one of roasted chestnuts. Ingredients: Flour, yolks of eggs, butter, and sometimes slightly flavoured with rosewater and nutmeg. After being mixed and rolled the paste is thrown into a seething cauldron of clear boiling water, and for the moment disappears, but rises in a short time ready for the attendant, who with a wire net plunges it immediately into a bath of cold water. The baking then follows.

Ordinary cracknels are of oval shape, depressed in centre, say, 3 ins. long by 2½ ins. wide, and ½ in. thick. About 25 to lb., and about 4¼lbs. fill an ordinary tin.

Fancy Cracknels or *Star Cracknels* are the names given to the same kind of biscuits when cut in various fancy shapes, oval, square, triangular, star-shaped, etc., about half the size of ordinary cup cracknels.

Toy Cracknels are so called from their smaller size, about ⅛ the size of cup cracknels. Price of all sizes the same, about 96s. per cwt.

Cranberries or **Bogberries.**—W., *Ceirios y Waen.*

The red globular fruit of the plant *Vaccinium oxycoccus*, not quite so large as cherries, and have a sharp, acid, and fairly agreeable taste. The cranberry thrives best in damp, marshy ground in cold districts. The plants are easily cultivated, and are found in North Lancashire, Cumberland, also in Scotland. The banks of the Dee, the Don, and the Spey used to produce large quantities. Enormous quantities are imported from Sweden, Norway, Siberia, Russia, New South Wales, etc. Doubtless the tough skin and the facility with which the fruit can be packed and shipped favours the cranberry business. The Scotch make a great feature of this branch of trade, some grocers handling several tons of the berries during the season.

CRANBERRIES.

The cranberries when gathered are merely put into casks, which are then filled up with water. They are quite sour, with a flavour approaching red currants, but are often filled fresh into bottles, kegs, etc., and used for pies, tarts, sauces, especally at sea for preventing scurvy.

In Russia a "Water Ice" is made from the juice of the cranberry gathered after it has been slightly touched by the frost, then sweetened and flavoured with vanilla. It is a great favourite with invalids on account of its sub-acid flavour, and is inexpressibly grateful to the fevered palate. Cranberry jelly is also extremely popular throughout Russia.

For *Cranberry Jam.*—Use a pound of sugar to every quart of fruit. The sugar, water, and berries should all go on the fire at once and be boiled rapidly for a short time—say, 12 or 15 minutes. No other method has been found to give so satisfactory a result.

American cranberries have been imported as far back as 1847, when the first barrels were shipped to this country. They are much the largest, and are of a brighter red colour, but are not equal to the smaller kinds in flavour.

Canary Cranberries generally come in cases—Baltic in kegs, American in crates. Much of this sharp acid fruit when crushed or damaged on its arrival in this country is bought up by the cheap jam makers to use along with old figs, dates, raisins, etc., in the production of their "Fruit Preserve" or "Mixed Jam."

Cray or **Craw-Fish.**—See *Lobsters.*

Cream —F., *Crême;* Port., *Nata;* Sp., *Crema;* W., *Hufen.* (See also *Clotted Cream* and *Crêmes.*)

A rich yellow crust which rises to the top of new milk when at rest, and consists mostly of small balls of fat, with a little serum and casein, the latter being a somewhat indigestible substance. The yield of cream from milk varies from 12 to 24 per cent., and may be increased by dropping into the milk a small piece of zinc. The time it takes to rise depends on the temperature. With the thermometer at 43 deg. Fahr. it requires 43 hours, at 50 deg. 36 hours, at 55 deg. 24 hours, at 68 deg. 18 hours, at 77 deg. only 12 hours, and at 80 deg. all the cream will rise in 10 hours. The larger cream globules rise first and so on to the smallest, which will scarcely rise at all.

The larger the globules the more easy the cream is churned into butter; hence the cream of the old milch cow is slower to churn than the large fat globules of the newly calven cow. The globules get smaller the longer she remains in milk. (See *Milk, Condensed Milk, Neapolitan Ice Cream,* etc.)

Cream Cheese.—Per., *Panir.*

These vary somewhat in composition; sometimes they are made from the raw creamy "strippings," sometimes from a mixture of milk and cream, but usually contain only about 5 per cent. of casein and from 50 to 70 per cent. of fat. They are generally made in small oblong, square, or round cakes, a light, steady pressure of 2lbs. to 4lbs. only being applied to press out part of the whey. After twelve hours it may be placed on a board or trencher and turned every day until dry. If kept it ripens in three weeks, but it is often eaten while fresh. A little salt and powdered lump sugar are often added. It is not properly a cheese, but merely cream dried sufficiently to be cut with a knife, and is of a soft buttery consistency and will not keep long.

They should be kept in a cool dry place, for dampness causes mould, and gives the cheese a bad appearance. If exposed long to the air or in a draught they are apt to run into a liquid, and become offensive to both the smell and taste, although the fashion is not to eat them until this decomposition has begun.

Never place the cheese on the shelves during the summer months, because the heat will cause it to run, and affect its flavour, so as to render it unsaleable.

It is often made from milk partly skimmed, so that the *real cream* cheese is usually called "double cream," and may be made either by curdling with rennet or from sour cream.

A good cheese should be made from the best quality of cream; 8lbs. of cream will make about two dozen 4 oz. cheeses to retail at 6d. each.

They are now often ripened by microbiological processes, and it is stated that amongst the numerous organisms concerned the chief part is played by the *Oosporo lactis.*

Any of these soft cheeses, such as York, Bath, Lincolnshire, Camembert,

Gervais, Pont l'Evêque, Coulommiers, Port du Salut, etc., sell readily, especially at seaside resorts and in large towns, and they can easily be made at any farmhouse, but the retailer should only take one week's supply at a time.

Cream of Tartar. — F., *Crême de tartre;* G., *Kremor tartari;* It., *Cremore di tartaro;* Lat., *Acid potassium tartrate;* Sp., *Cremor de tartaro.*

The powdered crystals of tartar which form out of boiling argol, or crude tartar, or, in other words, the purified and crystallised potassium bi-tartrate. It is, in fact, a combination of hydrogen, potassium, and oxygen; has an acid taste and gritty feel, and will not form into a paste. It should dissolve in hydrochloric acid, sulphuric acid, sodium hydrate, or potassium hydrate.

It should contain 99 per cent. of the pure bi-tartrate of potash. Mixed with bi-carbonate of soda it becomes an excellent substitute for yeast.

Tartar exists largely in grapes, and being insoluble in alcohol, it forms the deposit known as argol during the fermentation necessary in wine-making. Hence a large quantity is thus prepared from the hard saline crust, or argol, which forms on the sides of wine casks, in white or red crystals, according to the colour of the wine.

The argol is first dissolved in hot water, then treated with a little pipe-clay and animal charcoal to remove the colouring matter derived from the wine, and the filtered solution is then set aside to crystallise.

It is chiefly produced from this source in Italy, France, Spain, and Portugal, and largely exported in crystals or powder through Bordeaux in France, and Messina in Italy, either in 5 or 10 cwt. casks; the Italian coming from Bologna, Leghorn, and Venice is, however, the best. The importation from Bordeaux during 1897 were 38,048 cwts. of cream of tartar and 12,626 cwts. of raw tartar.

Cream of tartar is also now refined in both England and Germany, and these are sold at a guaranteed percentage of bi-tartrate of potash, which has not been the case with the French. The quality and value depend largely on the amount of refinement it undergoes and the amount of impurity taken out or left in. *Crystola*, *Cream Powder*, *Acid phosphate of calcium*, etc., are cheap substitutes or adulterants. (See also *Argol* and *Tartaric Acid.*) Cream of tartar is often adulterated with fine granulated rice, which is best detected by getting a chemist to heat 10 grains in a test tube, when a few drops of tincture of iodine will soon separate any starchy matter from the cream of tartar; or a simpler test is to stir half a teaspoonful in a large cup of boiling water, afterwards pour it into a glass tumbler, and if clear it is pure, but milkiness is a sign of adulteration; or it may easily be tested by direct titration and neutralisation with bi-carbonate of soda, that requiring the most soda being the strongest sample. The ignition process recommended in the British Pharmacopœia is very inconvenient and tiresome, also quite inaccurate when there is much calcium sulphate present.

A solution of 1·88 gm. of potassium bi-tartrate in 100 c.c. of hot water should require for complete neutralisation not less than 9·9 c.c. of normal potassium hydrate v.s. (each c.c. corresponding to 10 per cent. of the pure salt), phenolphthalein being used as indicator. Terra alba (white clay), alum, etc., are also frequent adulterants in cream of tartar.

Having regard to the Food and Drug Acts, it is safer for grocers to sell it simply as cream of tartar, and not as "refined" or "purified." A guarantee of purity should always be demanded.

Gardner's patent "Rapid" sifter and mixer, freely used for above. Prices from 50s. to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

For cream of tartar apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Creamery Butters. — (See also *Danish*, *Irish*, *Blended*, and *French* Butters.)

These are a class of butters manufactured at large factories, or "creameries," carried on sometimes by the co-operation of farmers and sometimes by private companies. The fresh milk is brought daily from a number of farms in the surrounding district, and after being tested (generally by Babcock's simple system) for its cream or fat contents the milk is at once heated and "separated" by steam machinery. In some creameries it is the custom to return the separated milk to the farmers at a fixed price, but in others it is manipulated into "condensed milk" and tinned. The cream, however, is quickly cooled and ripened to the proper degree, churned, coloured, and worked into butter; also salted, if desired, by machinery.

By this system a large quantity of the finest butter of uniform quality can be supplied to shopkeepers in large cities.

A "co-operative" creamery or dairy is an establishment erected and maintained by the farmers, either with their own money or by means of a loan obtained by them at a fixed rate of interest. The farmers, or milk suppliers, frame the regulations themselves for the conduct of business, and fix the prices to be allowed for the milk or cream bought, or other bye-products taken away.

Imitation Creamery Butter.—This is butter churned in the farm-dairies and gathered by waggons every morning. It is taken at once to the factory, at a central point, where it is washed, salted, and packed in paper-lined tubs, and sent to market while it is yet only two or three days old. (See also *Ladled Butter*.)

Creameries are now quite numerous in Ireland, but in some districts have not been so far very successful, especially where the farms are small. These farmers find the carrying of small quantities of milk to the distant creamery an irksome and comparatively expensive undertaking, and where the creameries condense the separated milk the farmers lose both it and the buttermilk.

Leading importers: George Wall & Co., Ltd., Liverpool and Manchester, selling agents for the principal Irish creameries (see advt. page 10).

Crecy. — The French name given to a variety of carrot produced in a district of that name. These carrots have long been celebrated in cooking, and are sold in a dry and preserved state; also mixed with other products, hence: *Riz Crécy*, *Tapioca Crécy*, etc.

Cremes. — The French word crème (cream), besides meaning milk fat, has several other applications. It is used to denote:—(1) Certain fine cordials or spirituous syrups (see *Liqueurs*); (2) the white interiors of certain chocolate bonbons, such as "Chocolate Creams"; (3) superior qualities of refined preparations, such as *Crème de riz* (rice flour), *Crème d'orge* (prepared barley); (4) table sauces, such as "Salad creams" and others made from milk, sugar, eggs, oils, etc., and variously flavoured with vanilla, coffee, cocoa, pistachios, etc.; (5) certain polishes for furniture, boots, etc., like "Furniture cream," etc.

Creosote. — This was discovered in 1830 by Reichenbach, who extracted it from the tar of wood.

Cretan Produce—The somewhat lawless island of Crete lacks proper cultivation and is only thinly populated, so that its exports are limited both in value and number. They comprise *Olive Oil*, *Raisins*, *Locust Beans*, and *Valonia;* also soap, wine, almonds (shelled), and a few oranges. The four first-named are those which find their way to this country, but the Turk does not bother much about statistics.

Cretan Wines.—There are two chief kinds, known as *Malevisi* and *Arhanes*.

The latter is of a dark red colour, containing 13 or 14 degrees of alcohol, and is exported to France in considerable quantities.

The former is of a rather lighter tint, and containing 14 or 15 degrees of alcohol. There is, besides, a white wine, which has no special name.

In 1894 70,000 *quintals* were exported from Candia, of which the greater part went to Nice, some to Egypt and Trieste, but none to Italy.

The exports from the port of Canea are only small, and the wines there are also of a dark red colour, the better kinds being known as *Kissamos* and *Ebraica*. About 1880, when the phyloxera was devastating the French vineyard, wine-growing in Crete received a great fillip, and the population neglected every other industry.

Cretan wines are very rich in alcohol. Cretan *Raisins* are chiefly consigned to Trieste.

Crocus Powder.—See *Red Crocus Powder*.

Crosnes.—See *Chinese Artichokes*.

Crumpets.—See *Muffins*.

Crushed Sugar, or **Crushed Lump.**—Commercial terms for inferior loaf sugar, crushed while still soft and moist, and packed in hogsheads or bags instead of being sent out in loaf form.

Crust Coffee.—See *Coffee Imitations*.

Crystallised and Glace Fruits, etc.—(See also *Candied Peels*, *Preserved Ginger*, etc.)

These are for the most part imported from France, Germany, Portugal, etc., in fancy boxes of 7 or 8lbs., superior qualities coming from Metz and Nice.

The chief kinds and approximate prices per lb. are:—Almonds, 2s.; Angelica, 1s.; Apricots, 1s. 6d.; Assorted fruits, 1s. 3d.; Bows, 1s. 2d.; Brochettes (small brooches), 1s. 1d.; Cherries, 1s. 3d.; Chinois (golden and green), 1s. 4d.; Citrons, or "Poncires," 8d.; Cornets, 1s. 1d.; Figs, 1s.; Ginger, Crystallised, 1s.; Candied, 10d.; Greengages, 1s. 5d.; Knots (Nœuds) (3 colours), 1s. 1d.; Lemon Peel, 5d.; Lunettes (spectacles), 1s. 2d.; Melons, or "Pastéques," 1s.; Mirabelles, 1s. 9d.; Orange Peel, 5d.; Pâtes, assorted, 1s. 3d.; Peaches, 1s. 4d.; Pears (white or pink), 1s. 3d.; Pine-apples, cubes, 2s. 6d., slices and lumps, 2s. 3d.; Plums, 1s. 2d.; Raspberries, 1s. 4d.; Strawberries, 1s. 8d. The preparation of several kinds in this country is, however, increasing.

Almond fruits similar to unripe peaches are made available for eating in this way only. The object of candying being simply to form a confection or sweetmeat imbued with the aroma, flavour, or medical property of any substance, candies are generally prepared by simply boiling lump sugar with a sufficient quantity of the infusion, decoction, tincture, expressed juice, or even the powder of the particular article, until a portion taken out and cooled becomes quite solid when it is either poured out on a marble slab or into tin, marble, or paper moulds, dusted with powdered lump sugar.

When the object is to crystallise the form and character of the fruit or vegetable in the candy the substance is boiled until soft, and then suspended in concentrated syrup, in the cold, until they become transparent, after which they are either dried in a current of warm air or in a stove at a heat not exceeding 120° Fahr.

The syrup thus penetrates into every part of the fruit, and prevents the natural decomposition that would otherwise occur.

The syrup must be kept fully saturated with sugar by reboiling it once or twice during the process.

The plums, greengages, etc., for crystallising are best gathered young and tender, before the stone hardens. Fruit preserved in this way keeps well,

and it would be a strict economy to thus *thin* heavily-loaded fruit trees, by utilising the excess, say one-half, and thereby improving the quality of the remainder left to ripen. The surplus, if not thinned, generally falls and perishes, so it would be all clear gain except the labour.

Crystallised and Glacé fruits, Flowers, etc., are prepared in much the same way in France. The business is carried on largely at Apt, in Vaucluse, at Clermont, in Auvergne, as well as at Marseilles, Grasse, Avignon, etc. The theory is to extract the juice from the fruit and replace it with sugar and water syrup, which on hardening preserves the fruit from decay, and at the same time retains the natural shape of the fruit.

The fruit should be graded, and only one size dealt with at a time. The exact degree of ripeness is all important, which should be under rather than over ripe.

Pears, pines, peaches, and quinces are peeled, and the larger fruits cut in halves; citrons are cut into quarters and soaked for a month in sea water, and the stones of apricots, peaches, and cherries are carefully removed without injuring the fruit. The fruit is then put into a basket or bucket, with a perforated bottom, and immersed in boiling water, which quickly penetrates the pulp, dissolving and diluting the juice, which is thereby nearly all eliminated, when the fruit is subsequently taken from the water and drained, leaving only the solid portion of the fruit intact. This process is called blanching, and requires great experience and care. The period of immersion depends on the size and ripeness of the fruit. If left too long the pulp is either cooked too much or is left too dry and woody; if taken out too soon the juices left in the pulp prevent perfect absorption of the sugar afterwards, and cause a fermentation which spoils the product.

After being thus scalded, some of the fruits, especially apricots, are sorted into two or three classes, according to the degree of softness produced, as, if kept together, they would take up the sugar differently, some losing their form entirely while others would take up very little. For these different grades sugar syrups of different thicknesses are required; the softer the fruit the heavier the syrup is needed. For the same reason each kind of fruit requires a suitable strength of syrup. Pears, citrons, and pines, which remain hard and firm, take a syrup of 18° to 25° density, while apricots, plums, and figs are treated with syrups which gauge from 30° to 40° by the aerometer.

The requisite syrup having been prepared by dissolving the fruit in pure water, the fruit is immersed in it, and left, for a certain period, in large earthenware pans, glazed inside, and having a capacity of about 8 gallons. The syrup penetrates the pulp, and gradually withdraws and replaces the remaining fruity juice, which, as it exudes and mingles with the transparent liquid, produces a certain filmy or clouded appearance, which marks the commencement of fermentation. When this has reached a certain stage the vessel containing the syrup and fruit is placed over the fire and heated to 212° F. This corrects the fermentation, and raises all impurities to the surface, whence they are removed by skimming. If the syrup is of the proper density this process of impregnating the fruit with sugar will be complete in about six weeks, during which time it is usually necessary to perform this heating operation, as above described, about three times. The fruit is then taken out, washed in pure water to remove any flaky particles that adhere, and is then submitted to one or two finishing processes, as follows: If the fruit is to be "*Glacé*"—that is, covered with an icy, or transparent coating—it is dipped in a thick viscid syrup of sugar, and left to dry and harden rapidly in the open air. If it is to be crystallised it is dipped into

the same syrup, but is then cooled and dried slowly in a kiln or chamber warmed to a temperature of 90° F. This causes the thick syrup with which the fruit is covered to crystallise, and assume the usual granulated appearance.

During the process of impregnating the fruit with sugar, the syrup in which it is immersed is gradually deteriorated by losing its sugar and absorbing the juices of the fruit. It is finally utilised in the preparation of *Confiture d'Apt*, which is made of the soft, uncooked, and irregular pieces of fruit of all kinds, mixed in irregular proportion, and preserved in the spent syrup, which is boiled down to the required consistency.

A quantity of plums, peaches, figs, and apricots come from Portugal packed up in round boxes of various sizes and decorated with paper lace, silver wire, tinsel, etc., making up a somewhat showy *tout ensemble* and not unsuitable for ornamenting a dinner-table. The process is simple in the extreme, and consists, roughly speaking, in boiling the fruit (before it is quite ripe) with sugar six times in the same water, after which the sugar is allowed to run off and the fruit is put on trays to dry in the open air. This manufacture in Portugal has been a kind of speciality of the nuns, but since the gradual extinction of the convents the trade has passed into other hands.

All candied and crystallised fruits, except candied citron, lemon and orange peels, are used without further cooking. Most of them are more particularly described under their separate names.

Crystallised Flowers.—In addition to the fruits above referred to, we have now from France and Turkey, violets, rose leaves or petals, orange flowers, and lilacs, crystallised in a similar way. Wholesale prices, 2/- to 3/- per lb. (See *Orange Blossoms.*)

Crystallised and glacé fruits, being put up and weighed fresh from the syrup, often lose 10 to 20 per cent. in weight on account of evaporation of the juices, but it is usual for the retailer to be charged the actual net weight at time of delivery.

Special Firms.—M. & W. Jones, Villa Nova de Gaya, Portugal; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; J. A. Sharwood & Co., Ltd., St George's House, London, E.C.

Cuago Nuts.—These globular seeds, about the size of a marble, are the fruit of *Myristica surinamensis*, first imported into Liverpool as oil seeds from Para in 1881. They have no smell and very little taste, but yield about 71 per cent. of solid fat, and the meal, after expression of the oil, is useful as a substitute for linseed in making poultices.

Cube Sugar.— Prior to the invention of ready formed cubes of uniform size, the sugar refiners turned out lump sugar in Loaves or "Titlers," which it was the business of retailers to chop into small lumps of irregular size and shape. It was a German who first showed how refiners might form their dry, granulated sugar into neat little cubes of any size desired. The late Sir Henry Tate and Messrs. Martineau joined in securing the German patent, and the Tate firm soon worked it out to the greatest advantage.

"Tate's Cubes" have now long been a household word. It is remarkable that the great refiner and philanthropist was originally but a retail grocer in Liverpool, who not only served his own apprenticeship to the trade, but also taught several others, some of whom are still alive and are proud to testify to the noble and industrious character of their esteemed employer. A few old grocers yet living can remember how in the fifties Mr. Tate's sugar refining began by his buying up, and experimenting on, any odd lots of damaged sugar that fell in his way. Encouraged by success, he subsequently joined Wright's Refinery in Manesty Lane, and eventually sold his grocery establishments. It should be a grand object lesson for the humblest member of the trade to see how this persevering grocer developed into the largest and most influential sugar-refiner, not only amassing an immense fortune, but giving away hundreds of thousands, and leaving behind him an ever-increasing

business; while nearly all the old-established and experienced refiners of his day have been relinquishing the sugar industry as a hopeless enterprise.

Cubeb Pepper (often called *Cubebs* or *Bennin Pepper*).—The genuine article is composed of the dried pedicelled berries of the vine or shrub, *Piper Cubeba*, or *Cubeba officinalis*, a native product of Java, Borneo, and Sumatra, but mostly imported into this country from Batavia and Canton.

They are of grey colour and about same size as common black pepper-corns, but somewhat longer, rather wrinkled, and with a short slender stalk.

Cubebs have a fragrant, agreeable odour, with a hot camphor taste, and, although once used as a spice, are now only employed medicinally.

Market value, 22/- to 30/- per cwt.

A spurious kind, distinguishable by a mace-like odour and taste, is frequently substituted in commerce.

Imports, about 60 tons yearly, *viâ* Singapore.

Cubic Nitre.—See *Nitrate of Soda.*

Cuca. — The Peruvian name for the fruit of *Erythroxylum Coca.* (See *Coca.*)

Cucumbers. — Du. *Kommommer;* F. *Concombres;* G. *Gurkern;* Ir. *Cucamhar;* Sp. *Cohombro;* W. *Chwerw ddwfr.* (See also *Pickles, Gherkins.*)

The fruit of *Cucumis sativus*, of which many varieties are cultivated, some rough skinned and some smooth, ranging in length from 2 to 18 inches. Some kinds are very bitter, and most of the cultivated sorts are bitter at the stem end.

The bitterness is thought to arise from an imperfect elaboration of the juices; these in the neck being least digested, and consequently more bitter. Greater warmth and light in cultivation is the best remedy. A common cause is the covering of the hot-bed in which they have been grown, but any check occuring in their growth will cause it, as, for instance, eelworms.

Cucumbers are considered remarkably cooling, and are often sliced up in salads. They are somewhat indigestible, but when properly dressed with plenty of oil may be eaten freely, and on the Continent form an important article of food.

Besides the frame cucumbers grown in England for table use, the plant is cultivated as a field crop, particularly in the home counties. In the market garden district of Sandy, in Bedfordshire, ten thousand bushels have been sent to market in a single week. These are cheapest in August.

Immense quantities are raised in Holland, Germany, and France, and thousands of hogsheads, preserved in salt and water, are imported into this country every year, mostly from Amsterdam and Rotterdam, all our large pickle manufacturers depending chiefly on Holland for these and other vegetables.

Before being put into the hogsheads (old claret casks) they are sorted into various sizes or qualities as follows:—

Fine Gherkins.—Young and tender, 1½ to 2 inches long, 40 to 80 to the lb. Prices, 50/- to 60/- per hogshead.

Bastards.—Larger sizes, crooked and mis-shapen fruits, 20/- to 30/-.

Chumps.—3 to 6 inches long and 4 to 5 to the lb., 20/- to 30/-.

Double Chumps.—4 to 8 inches long and generally soft and seedy inside, 15/- to 25/-.

"*Spotted Goods.*" — Fruits covered more or less with small black spots or rust, 15/- to 30/-.

The prices always include the casks, and vary considerably according to the crops and whether new season goods or old.

These cucumbers in brine are also largely eaten by the lower class of Jews, especially in London. The common practice of pouring off and wasting the brine is condemned as a wasteful practice, because it contains a large proportion of the natural juice of the cucumbers.

This juice, besides being valuable in medicine, may also be used in making pomades for the hair and cosmetics for beautifying the skin.

A brilliant green colour is often given to pickled cucumbers by heating them in copper vessels, which by some means, not chemically understood, imparts a sulphate of copper, but while improving

the colour it renders them dangerously poisonous.

Gherkins and cucumbers are often packed in bottles of green glass to lend the contents a fresh green appearance.

For wholesale quantities, apply to Allen Jeeves & Sons, Seddington, Sandy, Beds.

Cucumber Ketchup.—This is made from ripe cucumbers in the same way as mushroom ketchup. Mixed with cream or melted butter, it often forms an excellent sauce for poultry, etc.

Cucumber Mangoes.—A preserved sweetmeat prepared from young cucumbers (gherkins), and highly esteemed for its cooling properties. The antiquity of the cucumber is very great; it was a great favourite with the Romans, and in the 14th century was much commoner in England than at the present day.

Cudbear (Kud-ber).—A purple or violet powder, used in dyeing purple, violet, and crimson. Prepared from various species of Rocella lichens, especially from *Lecanora tartarea*, which grows on rocks in several parts of Northern Europe. It is partially soluble in boiling water; the colour obtained is somewhat fugitive, and it is used chiefly to give strength and brilliancy to blues dyed with indigo. (See *Orchella Weed.*)

Culilawan Bark.—See *Clove Bark.*

Culinary Essences.—See *Flavouring Essences.*

Culinary Herbs.—See *Dried Herbs.*

Culli.—A remarkable variety of maize (Indian corn), which grows in South America. Its grain is of a mulberry hue, and is often used to colour liquors, etc.

Culm.—A fuel which has derived its name from the geological term applied to carboniferous slatey beds in various parts of Europe.

Cumin Seed.—F. *Cumin Nigelle;* G. *Kuemmel;* It. *Cimino;* Sp. *Comino.*

A kind of aromatic fruit, or seed of the *Cuminium cyminum*, an annual, not unlike the wormwood plant and nearly related to the Anise, but stronger. It mostly comes to England from Sicily and Malta, but large quantities are grown in China. It is used in making curry powder, carminative flavourings, like carraway and anise, veterinary medicines, etc., and in Germany it is often used in making bread, also certain kinds of cheese. Norwegian anchovies in kegs are commonly flavoured with this spice.

In form the seeds are linear and flat on one side, and convex and striated on the other. They have a rather peculiar smell and a bitter aromatic taste. Usually retailed at about sixpence a pound.

Cumquats or **Kumquats.**—(See also *Loquats, Guavas*, etc.)—These are the fruit of a small shrub, or dwarf tree (*Citrus japonica*), a kind of orange about the size of a gooseberry, and oval shaped. They are extensively cultivated in Japan, China, and Australia, etc., for preserving or making into marmalade.

They are a very delicious and refreshing fruit, with sweet rind and acid juice, and the Chinese make a celebrated sweetmeat of them by preserving them in sugar.

Usually retailed in pots or small glass jars. Price on London market, 9/- to 11/- per case.

Curacao (often erroneously spelt Curacoa).—A popular liqueur mostly made in Holland from bitter oranges, *Citrus bigaradia*, which have dropped from the trees when young and green, about the size of peas or cherries. The peculiar sort grown in Curacao, one of the Dutch West India Islands, in the Caribbean Sea, is the most celebrated. In Curacao these small green oranges receive the greatest attention, and the fruit itself is only used with syrup to make a sweetmeat or *dulxe*. The *skins* are harvested for a constant market, the fruit being picked when the rind contains its maximum of oil, peeled in quarters, which are then dried, pressed and exported to Amsterdam in half-barrels. By distillation the oil is extracted from the skin or peel, and used to flavour the liqueur.

A good quality is made by Wynand Fockink, Amsterdam, and is known as

the "Curacao of Holland." The oranges are first soaked in water, and then distilled with spirit, which is afterwards reduced with water to about 56 underproof. Sugar is afterwards added at the rate of 3½lbs. to each gallon; a little rum, flavoured with cinnamon, mace, or cloves, is sometimes added. Curacaos vary in colour, and many are made in France. The darker kinds are generally coloured with powdered Brazil wood, and mellowed with caramel. Retail prices, sweet or dry, about 6/6 a bottle.

Curcuma Starch.—See *Arrowroot* and *Turmeric*.

Curd Soap or **White Soap.**—This when of the best quality is the purest soap of commerce. It is usually made from soda and purified animal fat, consisting largely of stearin, and a small proportion of olive oil is added to impart softness.

It often has a very light greyish tint, but otherwise closely resembles Castile soap. It is dry and nearly odourless, horny and pulverisable when kept in warm dry air. Soluble in rectified spirit and in hot water, and should impart a greasy stain to paper.

Curds. — F. *Caillebotte;* Per. *Most;* W. *Ceulfraen*.

A name for the coagulated or thickened part of milk, separated from the whey; and may, with pressure, be formed into cheese. Curds may also be eaten while fresh, either with or without cream, as a dainty, or used in making cheesecakes.

Currants (British). — There are three distinct types of English garden currants—(1) Black Currants or Quinsy Berries (*Ribes Nigrum*), (2) Red Currants, Wild Currants, or Garnet Berries (*R. Rubrum*), (3) White or Yellow Currants, which are really a variety of the Red. They are all closely allied to the gooseberry, and are referred to separately under their respective headings.

When cultivated in quantity for markets and manufacturies, the currants, both black and red, are generally gathered by women—black at the rate of 4d. to 8d. per half-sieve, according to crop, and red at 3d.

The fruit should be coloured, but not soft, or it will not travel well.

The half-sieves should be lined with paper, the fruit even in sample, sound, and free from leaves, and weigh 24lbs. nett. A sheet of paper should also be placed over the fruit, and the package finished with long green grass, kept firm with crossed sticks, the ends pushed through the top of the baskets and cut even. Large, well-ripened, red or white currants are often packed in 1lb punnets, or small, neat boxes or baskets (not returnable).

Currants (Dry). — F. *Raisins de Corinthe*, or *Passarelles;* G. *Korinthen;* It. *Uve Passe di Corinto;* Port. *Passas de Corintho;* Rus. *Korinka;* Sp. *Passas de Corinto;* W. *Rhyfion*. (See also *Patras* and *Zante Currants*.) (A corruption of the word Corinth, once famous for this useful fruit, and still called in some places *Corinth Grapes*.)

(Of course they are in no way related to the small black, red, and white species of *Ribes*, known as "currants" in our gardens.)

Currants, or Corinths, are the dried berries of the small black delicate species of seedless or stoneless grape, known as *Vitis vinifera*, var. *Corinthiaca*. This currant vine is very petted, and will only flourish in certain districts of Greece and adjacent islands. All attempts to transplant them in other lands have failed. It is also curious how these, and a few other vines, have practically lost the habit of seeding in those districts where they have been so long cultivated, and in those districts only, for even in other provinces of Greece the same plants will grow the berries of full size with the stones which are characteristic of the ordinary grape.

Currants are cultivated very extensively in the Islands of Zante, Cephalonia, and Ithaca, and especially in the vicinity of Pyrgos, Olympia, and Patras—which latter is the chief centre of the trade and port of shipment.

The best are those which come from Philicatra, Amalis, Patras, Pyrgos, and Kalamarta, also most of the growths known as "provincial." Excellent

qualities are also produced in Ægion (Vostizza) and the Kolpos district, and many of these are marked Vostizza on the cases, but not always.

Merchants have learnt to rely more upon the Bill of Lading than upon marks for proof of origin.

The crops are very uncertain owing to the attacks of a disease known as "Peronospos," which usually affects the leaves, but sometimes the fruit as well.

The average export of currants from Greece is about 150,000 tons yearly, of which one-third comes to England.

For a few years, 1878 to 1896, France took large quantities of pulped currants (*Raisins à boissons*) for use in wine-making, but the districts then devastated by the phylloxera being now replanted with American plants and the vines in bearing, France has suddenly ceased to buy currants. Indeed, stringent measures have been taken by the French Government for checking and repressing the sale by public wine-makers of drinks made from currant pulp.

In 1841 the average consumption in England of both currants and raisins was only 1¾lbs. for each person. Latterly it has been about 5lbs., and in addition to several other kinds of dried fruits unknown fifty years ago. The consumption of these dried fruits has, however, probably now passed its zenith, for fresh tinned fruits seem to be replacing them in public favour.

The currant vine, being very delicate, requires great care in grafting, pruning, trimming, and watering, and does not bear till six or seven years old, and the harvest, on account of thunderstorms, is very precarious. The berries are small, round, and thin skinned, of red and blue colours. As they ripen they are generally dusted with sulphur to protect them from the *Oidium*, and when gathered are usually dried in the sun.

The clusters or bunches vary in size, up to 300 or more berries, but they will not bear carriage and shipment to this country in a fresh condition.

The Government of Greece has established an ingenious but no less effective measure of encouraging home manufacture and at the same time augmenting its somewhat severely taxed finances. This is called the Retention Law, and it regulates every August the amount of currants available for export to about the quantity required by various markets of consumption.

The Greeks having found that the world's demand for currants is limited, and that an excessive export lowers the prices, to a decided loss to growers, the currant crop each year is surveyed and estimated, and, if considered excessive, each exporter has to deliver to the Government a fixed percentage of his export, so that prices can be kept reasonable. This reserved percentage, which varies according to season, is pulped and sold to distillers, wine makers, etc. As the worst currants are thus kept back, the fruit now exported is much better than it used to be. Currants yield excellent wine, and it is supposed that the first wine ever made was from dried grapes, for the history of currants goes back to mythology, and we are told that the Ancient Greeks for several centuries preferred such wine over that made from fresh grapes.

With a view to prevent currants being gathered and shipped before ripe, the Athens Legislature wisely passed a Bill in 1892 prohibiting any exportation of the fruit before August 28th, and enacting that anyone found guilty in that country of adulterating currants in any form or mixing old ones with the new should be liable to fine and imprisonment.

British steamers, already partly loaded and coaled for the run home, now congregate at the principal Greek ports ready for August 28th, and those supposed to be the swiftest have the preference of shippers.

New currants begin to arrive in England early in September. Grocers should be wary of false packed or repacked currants, the top and bottom of the barrel or case being sometimes packed with good currants, while the inside may be sweepings or rubbish, such as earth, sand, stones, and inferior decayed and discoloured berries.

Each package should, therefore, be carefully examined with the proper in-

strument, or searcher, a sort of long iron crowbar. The average weight in cases is 168lbs., half-cases 70lbs., quarters 40lbs., one-eighths 28lbs.

The Liverpool Drafts on Currants are according to actual weight of packages: —On 3 qrs. 27lbs., the draft is 1lb.; on 2 cwts. 3 qrs. 27lbs., the draft is 2lbs.; and so on, 1lb. extra for every additional cwt.

Until lately, it was necessary to wash or clean all currants before retailing them, but most of them are now fairly free from earth and other impurities, and can be sold without this trouble and loss. Fruit cleaned dry will keep, but washing it takes away the bloom, and injures the flavour.

Numerous machines for cleaning fruit have been brought out from time to time, but the best we have seen is made by Mr. Duckworth, of Colne. It far surpasses any cleaning by hand or otherwise, and is really serviceable. It is already well known as the Dry Conical Cleaner.

Wet or damp being liable to ferment currants and soon turn them sour, they should only be washed as wanted for immediate use, and, even if all right when retailed, they may spoil on customers' hands, and the retailer's reputation suffers.

They lose weight if kept long weighed and wrapped, but gain a little in our climate if kept in bulk.

Importers and Merchants.—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

The best machines for cleaning currants are sold by C. Duckworth, of Colne, and Parnall & Sons, Ltd., Narrow Wine Street, Bristol.

Currant Jelly.—See *Black* and *Red Currant Jellies.*

Curried Fowl. — F. *Poulet au Carry* or *Poulet à l'Indienne.*

Generally sold in tins, and consists of cold roast fowl cut up into small neat joints and stewed for about twenty minutes with sliced onions, chopped apples, curry powder, flour, and gravy, and flavoured with a little lemon-juice.

Sometimes a little butter or cream is added, also shalots or a little garlic.

Curry or **Currie** (from the Persian word Khurdi, meaning "broth" or lard). —F. *Carry.*

An Anglo-Indian sauce or relish, originally prepared in the East Indies, where the great principle seems to consist in the employment of cayenne to give *heat*, fruit to give *acid*, and of raisins or sugar to give *sweetness*. When prepared, it represents a kind of stew made of meat, fish, fowl, fruit, eggs, vegetables, with rice as a characteristic ingredient, and cooked with bruised spices, such as cayenne, coriander-seed, ginger, garlic, fried onions, etc., turmeric, apples, and lemon-juice being frequently added.

Any article of food cooked with this sauce is called "Curried," hence we have curried fowl, curried rice, etc., but curry in England and curry in India are very different. Curries, in fact, are made in great variety according to fancy, but have been strongly recommended for the poorer classes in this country, especially by the late benevolent Duke of Norfolk.

Curry Paste.—A condiment or food accessory prepared of same ingredients as curry powders.

Curry Powder. — F. *Poudre de Carry.*

A condiment of spicery sold ready mixed for making curry sauce. Used extensively throughout India and other tropical countries for giving a zest to other foods, where it seems an absolute necessity as a flavouring mixture. It is composed of turmeric, cayenne, pepper, ginger, and various spices, all ground or pounded into a fine powder.

The poorer natives are able to live almost entirely on rice, if flavoured with a few pinches of curry powder.

There is a great number of recipes extant for curry powders, and they differ chiefly in proportions, for the ingredients used are similar in all. Unfortunately for its popularity in this country much of the curry powder sold here simply consists of ground coriander-seed, turmeric, cayenne, and fenugreek, mixed with a large proportion of sago-flour.

The adulterants to guard against are red-lead, yellow ochres, excess of rice

flour, sago-flour, and other farina, also salt.

A dozen recipes are here given, but care should be observed that all the materials be fresh and finely ground :—

Quality.	Cardamom.	Cassia.	Cayenne.	Celery Seed.	Cinnamon.	Cloves.	Coriander.	Cumin.	Fenugreek.	Ginger (African).	Mace.	Mustard.	Nutmegs.	Pepper (black).	Pepper (long).	Pimento.	Rice Flour.	Salt.	Turmeric.

The quality marked N, with the addition of 1 cocoa-nut and 1 lime sliced, yields what is considered the closest approach to a Singapore curry that can be obtained outside the tropics. Sometimes a little garlic or shalot is added to currie powders.

Cardamom is not generally liked.

In India several of the above spices are used in a fresh or green state.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices, from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

For superior Curry Powders apply to Charles Cocks & Co., Reading, Berks; Allen Jeeves & Sons, Seddington, Sandy, Beds; J. A. Sharwood & Co., Ltd., St. George's House, London, E.C.—the largest dealers in the world.

Currier's Grease.—A softish fat, varying in colour from pale brown to nearly black, and smelling like leather. It is, in fact, the refuse remaining after being employed in treating leather with oil, tallow, etc., and therefore consists chiefly of tallow and fish-oil, mixed more or less with pieces and strips of leather, bits of wood, sticks, water, etc.

Used mostly by soap makers.

Cusparia. — See *Angostura Bark.*

Custard or **Sugar Apples, Atte, etc.** (sometimes spelt *Costard*).—Port., *Anonas.*

Titles applied to the delicious fruit of the *Anona reticulata*, native of Peru, and closely related to the alligator apple (*Anona palustris*). Varieties are now cultivated in most of the tropical countries of South America, Africa, East Indies, Carribbean Islands, etc., and also are commonly seen growing in a wild state in the woods near towns and villages along the sea shores of Western India.

The *Pawpaw* and *Bread-fruit* tree belong to the same genus.

It is a large greenish or dark brown roundish fruit, and from its size and shape often called *Bullock's Heart.*

But it varies in different species of the order from the size of an artichoke to that of a large pine-apple.

Its juicy pulp has, when ripe, the flavour of clotted cream and sugar.

The "Custard Apple" is a favourite fruit in Madeira, where it is in season from October to March, and when fully

ripe is most wholesome and nutritious. In Spanish-America one variety passes as the "Cherimoyer" (*Anona cherimolia*), and in the West Indies others are known as the "Soursop" (*Anona muricata*), "Sweetsop" (*Anona squamosa*).

From the old name "coster apples" was derived the term "costermonger."

Custard Powders.— These are usually compounds of corn flour, arrowroot, sago flour, or other meals, sweetened with powdered loaf sugar and flavoured with essences.

To each 4lbs. of the mixture is added about 1 oz of best powdered turmeric or saffron, to give a rich tint. The ingredients should be well dried previously, and 2 drachms each of bitter almond powder, cassia, and mace, or a few drops of the essential oils mixed well with the flour will do equally well for imparting an agreeable flavour.

Take 2lbs. of powdered gum tragacanth, 18lbs. cornflour, 4 ozs. powdered turmeric, and 2lbs. powdered sugar, essence of lemon and almonds to flavour. Rub the essences well into the sugar and then mix the whole.

The use of inferior turmeric, chrome yellow, etc., is sometimes noticeable in cheap makes. Others consist merely of sago meal coloured wtih turmeric, and flavoured with bitter almonds and cassia. The printing, advertising, and travelling are the principal items of expense.

A fair quality may also be made thus:—Dry and mix well together 8lbs. potato starch, 1lb. finely powdered gum tragacanth, a teaspoonful of finest powdered turmeric (light coloured and free as possible from smell), 10 drops of essence of lemon, and 5 drops of bitter almond oil. Keeps best, cool and dry, in closed bottles or canisters.

Special manufacturers:—De Carle & Son, Fruit Drink Works, Norwich.

Gardner's patent "Rapid" sifter and mixer freely used for above. Prices from 50s. to £10c. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Cut Cakes.—See *Slab Cakes.*

Cut Flowers.—See *Flower and Nosegay business.*

Cut Sugar.—A shop name for loaf sugar cut or chopped into prismatic forms, generally cubes.

Cutch or **Kuth.**—See *Catechu.*

Cuttle-fish Bone. — F., *Os de Sèche;* Lat., *Os sepiae.*

This is the light and friable bone which forms the back of the cuttle-fish (*Sepia officinalis*). It was formerly much prized in medicine as an absorbent; but its chief uses now are in polishes for metals, making of pounce, and tooth powders; also for serving to cage birds to clean and sharpen their beaks (see *Poultry Foods*). Large supplies come from China, Persian Gulf, and Bombay.

Cuvee. — A French term, used in much the same way as the English nouns—"batch," "brew," etc.—but denoting wine which has been made at one fermentation, at the same time and in same *cuve* or vat, as we say "same batch," "same brew." "*Première Cuvée*" is a phrase denoting wine made from juice which voluntarily flows from the ripe grapes without pressure, and is supposed to be more luscious than the subsequent *cuvées*, which are obtained by pressing or treading the grapes.

Cwarra Wine.—One of the best Australian wines, made from the genuine juice of the grape, and somewhat resembling Rhenish wine.

D

Daffys.—An old shop term for a tincture of senna and brandy.

Dalmatian Insect Powder.—See *Insect Powder*.

Damascenes (sometimes called *Shropshire Damsons* or *Black Jack Damsons*).—A variety of smaller size and rounder form than proper damsons, and inferior in flavour.

Dammar.—A highly-valued gum, of which there are extensive deposits in Palawan and Mindanao (Philippine Islands). The exports vary from 200 to 500 tons a year.

Damsons.—F., *Prunes de Damas;* W., *Eirinen.*

These well-known small black plums are so named from the city of Damascus.

They are rather apt to disagree with delicate stomachs, and also to affect the bowels.

Besides being made into jams, jelly, damson cheese, etc., they are often preserved as bottled fruits.

Fill the bottles with fruit—not too ripe—shaking or knocking the bottom of the bottle on the table, so as to get in as many damsons as possible. Then wash off by filling up the bottles with clean cold water, shake and pour off the water and refill with cold water that has been boiled; cork well, and tie down the cork with strong twine, then place the bottles upright in a tank or large flat-bottomed pan; fill up the pan or tank with cold water, until the water nearly touches the corks, and then heat the water up to 191° Fahr., and keep it so for one hour, when the heat should be lowered to 181° for same length of time. Let them cool slowly and steadily, and remove from the pan. Afterwards, the tops of the bottles and corks should be dipped in melted wax or resin, or covered with tin-foil. Finally, polish, label, and wrap in paper, or store in a dark cool place.

Damson Cheese.—This is often miscalled Damson Jelly. It is generally made in the following manner:—1 cwt. of damsons are boiled briskly for half-an-hour in six gallons of water. When quite soft the pulp is rubbed through a fine sieve or strained through a flannel bag, and the stones thrown out. Some makers crack a few of the stones and boil the kernels along with the above to impart a more decided flavour.

Equal parts of the pulp and loaf sugar are then boiled slowly, and stirred frequently till stiff as thick treacle, or until it sets firm in a spoon. (Some use only a quarter as much sugar.)

When properly made and cold it cuts like ordinary cheese, and not like jelly.

Damson Jam.—(See aiso *Jams.*) Recipe:—15lbs. of fruit, not quite ripe, boiled with 14lbs. of sugar, will make 28lbs. of very good jam, but the best is that made in large batches, and boiled rapidly by steam.

Dandelion Coffee or **Taraxacum,** should consist of the roasted and ground roots of the common dandelion.

The word is obviously a corruption of the French name for this plant, *dent de lion* (lion's tooth), and so called from its deeply notched or tooth-shaped leaves. The Latin title is *Taraxacum dens leonis*, hence it is often called taraxacum.

The roots, which possess valuable medicinal properties, when fresh, are first washed, sliced, and dried, colour being added in the form of a little caramel, and finally mixed with ordinary coffee or chicory.

A good dandelion coffee should contain about 8 ozs. of the powdered root, 1 oz. chicory, and 3lbs. ordinary coffee, but some are made up mostly of chicory and caramel, with very little powdered dandelion; and, indeed, analysts say it is very difficult to distinguish when powdered.

The dandelion root, when fresh, is frequently a foot or more in length and half an inch or so in diameter, smooth and yellowish-brown externally, white within, breaks readily with a short fracture, and contains about 30 per cent. of milky juice. When dry the root is shrivelled to a quarter its original weight, deeply furrowed longitudinally, dark brown or brackish, breaks with a short fracture, and the exposed interior shows a yellow porous central woody axis, surrounded by a thick whitish bark with a variable number (according to its age) of irregular but well-marked concentric rings. It is inodorous and tastes bitter.

Good dandelion coffee acts as an alternative and tonic, and is good for the liver if taken once or twice a day regularly for a week every now and again.

Danish Bacon. — Although Denmark is a cold, flat, bleak country, which would disappear if the tide rose as high as it does in the Severn, yet this little country, with a population of only one-third of that of Lancashire, manages to send annually £10,000,000 worth of bacon, butter, and eggs to England. Why? Because the directed and instructed intelligence of the Danish farmer and the co-operative system beats the ignorant, conservative, and self-satisfied English farmer on his own market

About half the pork and bacon exported to England from Denmark is cured by the co-operative curing-houses of the latter country. The rearing of pigs has always been of great importance in so pronounced a dairy country as Denmark, because the dairies supply a vast quantity of food for pigs. The number of these animals reared has of late very considerably increased, owing to the enormous quantities of cheap Black Sea barley which has been imported into Denmark during the last few years, and which has been used for fodder. The bacon business has come about rather curiously. In 1890 and 1891 the number of pigs exported rose to very high figures; but in 1892, in February, the English market was closed for Danish live pigs, and although a large number were exported to other countries, this was attended with great difficulties, and there remained a large number for which no market could be found. This naturally induced farmers to export their pigs in carcases, and the co-operative curing-houses, which had already begun to be established in 1888, were greatly increased, and at the end of 1894 there were about 18 larger and smaller establishments spread over different parts of the country, the largest establishment slaughtering about 40,000 pigs a year. At the end of 1896 the numbers had increased to 18 private and 23 co-operative slaughter-houses. The principal advantage of the co-operative system was the doing away with the middleman. This advantage still exists with the co-operative curing-houses, and as a whole they are said to work well. For small cottagers it is, of course, of great importance to get a good price for their pigs, whereby they are induced to rear them. Every shareholder, without regard to the number of pigs delivered, has but one vote in the matters of the curing-house. The co-operative curing-houses are generally started in the following manner:—All the farmers and others who rear swine in a district, the radius of which if taken in a circle is about 8 to 12 miles, unite together and raise the amount necessary for the plant and starting of the curing-house by signing sureties, according to which they are responsible for the payment of a certain amount answering to about 10 kroners (1 kroner equals 1s. 1½d.) for each pig, stipulated in the bond for the delivery of swine to which reference is made below. Very often all the farmers in one parish act as a whole, so that their obligation is limited to the amount raised in the parish. These bonds of security are then deposited in the bank

in which the loan necessary for building the curing-house is raised. The rules of the curing-house generally stipulate that the said loan shall be paid off in ten years, after which period the curing-house is owned by the shareholders in proportion to the number of swine delivered. The obligation to be surety is very binding, and generally lasts for a period of ten years, and very detailed and strict regulations are made respecting the transfer of the obligation to others.

The participants further bind themselves to deliver *all* the swine they rear to the curing-house, and severe fines are imposed for any swine sold to others. The shareholders are as a rule bound to deliver swine at the curing-house or at the nearest railway station, whence they are taken to the curing-house at the expense of the establishment. Settlement is made according to dead weight, the swine being divided into three different classes when slaughtered. Payment is generally made within eight days of the delivery, with the deduction of 1 kroner per 100lbs. The amount thus retained is used for different purposes, *e.g.*, to collect a reserve fund. At some of the curing-houses three-fourths of the value of the swine are advanced to the farmer on delivery, according to the prices for live swine. The prices paid for the swine are fixed in the following manner. In every curing-house there is a Quotation Committee, generally consisting of the manager, the chairman, and a shareholder. These committees fix on a proposal, which is then sent to the Central Quotation Committee, at Horsens (Jutland), where the final quotation is fixed. At every curing-house there is a shop for the sale of sausages, fat, etc., and as a rule these pay exceedingly well, and form a great part of the profit of the curing-houses. The pigs are crosses with Danish and the large and medium white Yorkshire breeds, and are fed to be killed at five or six months old.

In 1883 the total export of bacon from Denmark was only 9,121 tons, but for 1894 it amounted to 41,225 tons and the increase still went on. In 1896 the number of pigs slaughtered exceeded 1,200,000, an increase of 25 per cent. over 1895.

In 1897 the United Kingdom alone received 51,327 tons.
" 1898 " " " 50,876 "
" 1899 " " " 60,530 "

The special brands are *The "Royal Crown"* and *The "Royal Dane,"* imported by George Wall & Co., Ltd., Liverpool (see advt., page 10).

Danish Butter.—The manufacture of Danish butter has shown a marked development during the last 30 years. About 60,000 tons are now exported yearly. As in the case of bacon, this progress is due to the highly-trained intelligence, resourcefulness, adaptability, energy, and enterprise of Danish farmers, the power of organisation, and the effectiveness of Government expert advice and support. It was brought about in the first instance by operatives from Holstein, who first began to use the thermometer, the scale, the burette, with other improvements into the dairies of that country.

In the manufacture of butter both refrigeration and pasteurisation are employed. The pasteurising process is a very simple one, and is designed with a view to the destruction of certain germs or spores which exist in fresh milk. The milk is received in the receiving tanks from the farmers, and as it is taken into the dairy samples are taken to be tested afterwards by butterometer or other handy means for butter fat. The milk is then run through the pasteuriser. This is a very simple device, consisting of a jacketed pan, inside of which there are fixed beaters or agitators, so as to quickly bring the milk in contact with the heated surface of the pan. The milk flows in by gravitation, and the centrifugal force exerted by the beaters forces its elevation high enough to enable it to flow into the separators.

Here it is at once separated, and the cream is collected and cooled by means of Schwarz pans, or better, by passing over the capillary surface of a circular or flat cooler, in which chilled water is running or brine is being circulated.

This cooling of the cream is a very important matter, as the quicker it is cooled, to say 55° F., the sooner is the ripening begun and the butter produced. The butter is stiffened in the chill rooms before being sent out generally at a temperature of 35° Fahr.

Although it is made every day, it is not sent away from the dairies generally but once a week, so that it follows that some of the butter when sent away from the dairy is a week old. It is generally sent in the beginning of the week to the exporter to be shipped at the end of the week, and in this way it comes into the market at the beginning of the next week. It is obvious, therefore, that to efficiently conduct the dairy business requires considerable capital.

The Danes make fresh butter all the year round. They manage to have milch cows coming in all winter as well as summer. Some think that the pasteurisation process, while removing any bad taints from milk, cream, and butter, also at same time destroys much of the fine flavour; and although the butter is mild, more uniform in quality, and will keep a longer time, it lacks the best traits of other fresh butter, and is apt to acquire an oily taste. Of course, other butters—such as Irish, which have been preserved or cured with borax, etc.—will keep longer, but the only preservative added by the Danes is about 1 per cent. of salt.

There are two kinds of Danish butter —*sweet butter* (södt smör), made from the cream which is collected as soon as it rises, and *sour butter* (syrnet smör), made with cream that has been allowed to sour a little.

This latter kind is much more delicate, and is mostly exported.

The churn used is conical shaped with a vertical axis, containing in the interior three churns placed vertically, to arrest the gyratory movement of the cream.

Danish butter is not graded; only the finest or freshest is professed to be shipped. When any grows stale, of course, it is for any seller to describe it as he pleases, but to call it fresh would be fraudulent. It is doubtful whether the Danish system would work well in England under present conditions, and where milk fetches 6d. or 7d. a gallon. It takes 2½ or 3 gallons of milk to make a pound of butter, so that as things are the English farmer would have to submit to a loss of about 30 per cent. on the market price of the milk.

The butter when made is packed in little beechwood barrels or kegs, containing 14, 28, or 36 kilogrammes, and the brand must be burnt in every package.

DANISH BUTTER PRICES.

reduced to Danish currency pr. 100 pounds at the exchange of £1 = Kr. 18.10 (90 ore = 1/-).

The Danish "pund" is equal to half a kilogramme or 1.102 lbs. (avoirdupois).
112 lbs. English calculated equal to 102 punds Danish.

It should be understood that not all the butter from Denmark is real Danish. Much of it is first imported into Denmark from Sweden, Finland, Siberia, etc., and it is said that some unprincipled parties refill Danish butter casks with foreign mixtures or margarines.

Leading importers of Danish butter. —Geo. Wall & Co., Ltd., Fennel Street, Manchester, and Liverpool (see advt., page 10); Thomas Wilson & Co., 3 Hood Street, Liverpool.

Dari, or Daly Seed. —(Also known by the African names of *Durra*, *Dhurra*, or *Dourrah*.)—These are several names for the seed, or coarse meal, yielded by the sorghum (*Sorghum Vulgare*), or Chinese sugar cane, *Virola sebifera*, extensively cultivated and used as food in Egypt, Africa, and India.

During the Soudan war our soldiers were largely indebted to it for food. (See also *Millet*.)

The seeds are round, whitish in colour, and somewhat larger than mustard seed. An excellent wax for the manufacture of candles is also obtained from it; but the seed imported into England is chiefly used for bird, game, and poultry food, and the rigid stalks for brooms and whisks.

Dates. — F., *Dattes;* G., *Datteln;* It., *Datteri;* Sp., *Datiles.*

The fruit of the common or greater date palm, *Phœnix dactylifera*, which now forms an important object of cultivation in Africa, India, Brazil, Arabia, Persia, Barbary, and Spain. It is, however, only in Northern Africa, Morocco, Algeria, and Tunis, under the hot and dry sky of the desert regions, or of those which are not distant, that the more edible varieties grow in profusion. The dates which grow in the environs even of Algiers, at Dakar, St. Louis (Senegal), and at Rio de Janeiro are not so good, because they grow in relatively moist climates, whilst the fruits coming from the oasis of Central Sahara and Tunis have a delicacy of taste not met with elsewhere, particularly the "Degla" and "Horra," packed in small boxes.

These fruits are large, tender, and very sweet, of a golden brown colour, and with the skins unwrinkled. They are grown chiefly in the famous forests of Jerid (Djereed) and Tuzear, but in the north of Tunis dates do not ripen well for want of heat.

There are scores of varieties, among which the *dakkar* or *menakkar* (male date) is pre-eminent. Probably no other fruit combines in such a convenient form the principal elements for the sustenance of human life as the date, and this without cooking or preparation of any kind.

The naked and cylindrical stem of the tree generally grows straight to 40 or 50 feet high, and at the top opens out a large cluster of 40 to 80 feather-shaped leaves, each 8 to 10 feet long, and amongst which some 400 or 500 lbs. of fruit hangs, in bunches of 20 to 30 lbs. each.

The trees do not bear fruit until 8 or 10 years old, but live to more than 100 years. They require great heat—not less than 100° F.—and will not flourish within 25 miles of the sea.

The ordinary date fruit is an oblong drupe, shaped like an acorn, but twice as large, and consisting of a coarse, but sweet and rich pulp, covered with a thin yellow skin. In the centre is a single, hard, horny seed or kernel, which has a deep groove on one side and running its whole length.

In spite of their sweetness, dates do not cloy the palate like other fruits, and as a sweetmeat for children they are considered excellent. In this country the consumption has quadrupled in a very short time.

The date tree is perhaps one of the most useful in the world. The Arabs say it loves to have its feet in the water and its head in the fire. Its fruit was the lotos of the *Lotophagi*, or lotos eaters. In North Africa and Arabia the

trees are preserved as family estates, and handed down as dowries. The trunk supplies timber for houses and fences, and wood for fuel; the leaves form baskets, bags, mats, fans, brushes, walking-sticks, ropes, cords, roofs, and walls, and the fruit the chief food to millions of people in Arabia, Barbary, etc. Spirits, sugar, honey, and vinegar are also made from it. A liquor, known as palm wine or *latchby*, is obtained from the sap of the date tree. Even the young shoots and the tender unfolded leaves are also eaten as *palm cabbage*, while oil, "date coffee," and cattle food are made from the stones. "Arrack" is also made from the sap of the shoots.

The best dates, however, as already stated, are brought from Africa, by way of Tunis, and include those of Tafilat, a very tender and sugary kind but limited in quantity, grown 200 or 300 miles inland of Morocco, a part to which a European has rarely penetrated.

The *Tafilat dates* used to be packed in large cases of 1½ cwts., but now come in small clean fancy boxes, and are very delicious.

Immense quantities of dates come from Smyrna, Barbary, and Alexandria, and the Egyptian fruits are much larger and very luscious when new, but are very fibrous and soon go hard.

The plantations in Algeria are of immense area. The chief are those in Souf. Nearly every green and fertile spot in the desert which owes its existence to a water spring is known as an "*oasis*," and is planted with date palms. The oasis of Touggourt possesses 400,000, and forms a long band some 15 miles in extent; at Toyer there are 250,000 trees; in the oasis of El Hamma, 200,000; in the territory of Gafsa, oasis of Ouden, 200,000; and in the Nefzarouen plantations in Tunis, 300,000.

The popular methods of preserving dates are either drying them in clusters before they are too ripe, and then arranging them in small ornamental boxes, or cartoons, which are exported 50 or 100 in a case, or, which is the older system, leaving the dates on the tree till quite ripe, and then pressing them into a solid mass, "djoue," or cake in baskets or bags. These are called *Squashed dates*, but box-packed dates are now much preferred, and the demand for skin or basket-packed is becoming neglected.

Bassorah or *Bagdad Dates*.—There are some excellent varieties grown in the provinces of Turkish Arabia, near the Persian Gulf—in fact, the trade of Bassorah, Basra, or Basrah, on the Tigris, consists almost entirely of dates. Formerly they came in mats, baskets, and skins only, but now they arrive neatly laid in clean whitewood cases of about 63lbs. net and in small cardboard boxes.

The principal are the *Hallawee* (a golden fruit with a delicate flavour of honey), the *Khadrowee* (a red or brown fleshy fruit of firm consistency), the *Sayer* or *Sair* (a dark sweet fruit, the wild date of the country), the *Deri* (very scarce, with a delicate raspberry flavour), the *Koorsi*, from Bagdad (a bright golden fruit), and the *Zahdi* (a similar fruit of rather redder hue).

The Bussorah and Bagdad date business is now almost wholly in the hands of four or five British firms.

White Dates.—A small white variety from Egypt, about the size of acorns and nearly as smooth.

Trebizonde Dates, the fruit of *Elæagnus Orientalis*, are popularly used in the East as dessert, and for making a sort of sherbet; but Persian dates are not equal to those grown and shipped at Bussorah, although they are still sufficiently appreciated to secure a steady demand. Date palms in Persian Beloochistan begin to yield at three years. A good crop for a single tree is 80 to 100lbs. The dates used for export are those that grow at the summit of the tree. From the action of the sun they become hard and dry, thus being easily packed. The fruit on the lower branches remains soft, and is kept for local consumption.

It is said that nineteen-twentieths of the population of Fezzan live on dates

during nine months of the year, as also the animals, and that the first question of a Bedouin is, "What is the price of dates at Mecca?"

French dates are not fit to eat, containing, as they usually do, the eggs and excreta of insects.

The wild date tree, *Phœnix sylvestris*, grows all over India. The fruits are very small and almost pulpless, but the natives eat them, although the principal use made of the tree is for extracting its sap for "toddy" making and in Bengal for "*date* sugar" making. There are as many varieties of dates as of apples. While in their unripe state they assume a red or yellow shade, and are then crisp like apples. At first astringent, they then become sweet and nutty. In this stage the natives in the Persian Gulf eat largely of the fruit, also preserve it by boiling it in water and drying it in the sun, when it will keep for a year. Certain varieties of dates do not ripen beyond this, the "Khárák" stage, and can only, therefore, be preserved by the boiling and drying process; while other varieties ripen till soft and perfectly sweet. This is in Persia called the "Khoorma" state. These will not keep good more than two or three days unless dried in the sun. Usually the dates are gathered as they ripen by shaking the tree. It is only certain kinds that can be left on the tree to ripen in bunches.

Dates keep best when closely packed so as to exclude the air, and when in parallel layers are easily broken out for use; but the stickiness of the fruit is such that shop assistants need to wash their hands afresh every time loose dates are handled, so that the 1lb. boxes are preferable in this respect. If packed in an unripe condition they are almost useless. They should be chosen large, soft, plump, and of a yellow or light reddish colour outside, but whitish towards the kernel, flesh solid, juicy, and viscous, and of a sweet vinous taste.

Dry, hard, and wrinkled qualities are very inferior but they are now largely used in distillation and in the manufacture of vinegar. Low priced dates are apt to be affected with a parasitic disease known as the *date-smut;* it occurs in the interior of the fruit, and converts it gradually into a sooty mass. The parasites being very reproductive, they rapidly make the fruit quite unsaleable.

For all kinds of dates, apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Date Coffee.—A preparation made from torrified dates and mixed with coffee, in the proportion of about one-fourth coffee and three-fourths dates. It is a dark-brown, rather sticky powder, having a sweetish smell, but no coffee odour. On being thrown into water, the water is immediately coloured, as the powder sinks to the bottom. There is scarcely any trace of caffeine, but the large amount of sugar present clearly distinguishes it from genuine coffee.

For the laws and regulations regarding Date Coffee, etc., see *Imitation Coffees.*

Date Plums.—See *Kaki.*

Date Sugar.—See *Palm Sugars.*

Date Vinegar.—As the name implies, this is produced from dates. The dates are first stoned and then mixed with water. The water dissolves out the sugar and other soluble constituents of the fruit, producing a liquid from 9° to 1° B. The wine is next filtered, and then acetified in casks by a quick process.

Finally, it is sterilised and clarified.

Date vinegar possesses the properties of ordinary wine vinegar, but differs from the latter in being much stronger and containing less alcohol, the strength varying from 6° to 8°. It is also much cheaper in price.

Dehesa Raisins. — Retailers have doubtless often seen upon boxes containing Malaga raisins the word "Dehesa," and may have wondered what it really meant. No "Dehesa" is to be found upon the map—the gazetteer is silent about it, and the dictionary gives no clue!

Now the word "Dehesa" simply means a *pound*—not a sovereign, nor even a pound avoirdupois, but a pound

or penfold for stray animals, such as are common in nearly every English village, except that the Spanish variety is larger.

Well, some years ago it seems one of these "dehesas," or pounds, having outlived its usefulness, was accordingly sold to an enterprising senor, who converted it into a vineyard. Its long occupation by sundry oxen, pigs, sheep, and mules, to say nothing of the luckless jackasses that abound in every part of Iberia, had given its soil an unusual richness, and the result was a crop of grapes of immense size, from which the largest and finest raisins were made. So the lucky senor adopted the name for his fruit, until "Dehesa" raisins have become known wherever plum-puddings are eaten. We will not say that all the Dehesa raisins in the market came from these pounds, for this would be expecting too much even of high-toned *caballeros*, but there is little doubt of the origin of the word in this connection.

Dehesas are very apt to be closely packed and made very pretty at the top, although in the under layers they have often been little short of a fraud. Very few, however, are now met with; and the Muscatels, or dessert raisins, from Malaga (which come in brightly decorated boxes) have nearly driven out of the market the Dehesa variety.

Dehydrated Fruits and Vegetables.—In addition to Dried and Evaporated Fruits, we now have sliced dehydrated fruits—such as apples, pears, and apricots—which in a dry form can be closely packed, will last long, and on being soaked in water regain their natural physical characters, as well as their original flavours. This perfection is attained by the careful selection of fruit, and judicious drying in closed but ventilated appliances. What has been done with fruit is now being done with vegetables. At the present time vegetable garden produce is being preserved in England mostly by the simple process of dehydration. This has been carried so far and so successfully that even beetroot in thin slices can be dried hard, yet retaining all its characteristics, including colour, and when these slices are soaked in pale malt vinegar they swell, become tender, and impart a bright red tint to the liquor. It is to be noted that the process is merely one of systematised preparation and drying, no chemicals are used, and yet flavour and colour are absolutely retained. It is clear enough that this improved system of drying has many advantages over some other methods of preserving foods. There is reduction of bulk, lessening of, and when properly packed, complete safeguard against, the dangers of fermentation, and the exclusion of all added chemical antiseptics, which, as commonly used with fresh or bottle fruits, must have a more or less decided influence on digestion. Moreover, these dried vegetables and fruits can be quickly prepared for consumption, and can be kept for travelling, or for storage against seasons of scarcity, with far greater ease and sense of security than edibles put up in glass or tin. In more than one direction this improvement in desiccation has been applied to flesh foods with some amount of success. Indeed, as regards the drying of eggs the process proves of the highest excellence and utility. The dried eggs, in powder or small oval pellets, have merely to be soaked in a little water, when they can be beaten up and used for every description of culinary work with absolutely satisfactory results. Considering the reliance that one must place in eggs in invalid dietaries, and the unreliability of their supplies under various circumstances, this victory of the manufacturers is a veritable boon. A welcome feature in this new phase of food preserving is that the provisions are generally of home growth and British manufacture, and will thus prove a help to the farmer as well as to the consumer.

Delicatessen.—A German term for dainties, or the superior confections sold by grocers.

Demerara Sugar.—A name originally given to cane sugar grown and shipped from British Guiana, but now commercially extended to all crystallised

sugars from that quarter, including Guiana, Honduras, Jamaica, Trinidad, St. Kitts, St. Lucia, Barbadoes, and other British West India Islands. These rich cane sugars are all very much alike and about the same in value. There is no denying the fact that they are really cheaper and better in every way than beet sugars, but beet sugars being whiter and about a halfpenny per pound lower in price, silly housewives get the beet. The grocer might do well to remind customers occasionally that *sixpenny-worth* of Demerara is much richer, sweeter, and more wholesome in every way than *nine pennyworth* of beet.

Demerara sugar is imitated by certain refiners, or rather sugar dyers, who have special machinery for colouring the larger crystals of beet sugar with "Nicholson's blue" (iriphenyl rosanaline sulphonic acid), or other aniline dyes of amber tint, in order that these foreign beet crystals may be palmed off on the public as genuine Demerara, and consumers cheated out of about ½d. per lb. This spurious product is usually harmless, but in the manufacture of some of them *stannous chloride* is employed in the vacuum pans, it having largely superseded sulphuric acid for this purpose; the chloride, however, passing into the molasses, becomes a very objectionable constituent of that product.

One thing is, however, certain, the reputation of Demerara has from above causes greatly declined; and unless the public analysts intervene, it seems likely to go entirely out of the market. A few retailers still stock the lower qualities, but very few now keep the best.

The sale of artificially coloured "Yellow Crystals," when Demerara is asked for, is, of course, under the Merchandise Marks Act, a fraud on the consumers, as also upon the cane sugar producers.

Genuine Demerara derives its yellow, lemon, or golden colour naturally from the cane juice, and is not coloured with any artificial dye; although in the last stage of refining it a little chloride of zinc is generally employed to impart a bright complexion or "bloom." Owing to its peculiar rich flavour, Demerara sugar is not suitable for jam or marmalade making until highly refined.

In its original state or first stage in the process of refining, where it is made prior to shipment, crystallised Demerara sugar is always white, and it is straw-coloured or rendered yellow only to suit the fancy and please the eye of the British consumer; consequently, "pure white Demerara" is very rarely seen in this country.

A very simple but infallible test for genuine Demerara is to put a spoonful of the suspected sugar in a tumbler of water, if it turns the water a CLEAR yellow and leaves the sugar quite white, it is a proof of artificial colouring; but genuine Demerara merely turns the water *cloudy*, but without colouring it; however, the smell is generally sufficient.

Special Importers.—The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.; Graham Brothers & Hay, 16 Stanley Street, Liverpool.

Demi-Suisse Cheese.—See *Gervais*.

Dendang.—(See also *Charqui*.)—A name for dried meat in the Eastern Archipelago. It usually consists of the flesh and sinews of the buffalo, deer, or wild hog, dried quite hard by exposure to the heat of the burning sun.

Denia Raisins.—See *Raisins*.

Dentifrices.—Powders or other substances used for cleaning the teeth. Often made by burning and powdering fish shells, which when so treated acquire a caustic nature.

The term used to be confined to powders, but is now also applied to liquid preparations intended for the same purpose.

A good dentifrice should contain an antiseptic to kill bacteria and check fermentation which is constantly arising in the mouth from many causes. Tartar is injurious to the teeth, and should be moved by mechanical means.

Deodorisers (for bad smells).—These preparations are not necessarily disin-

fectants (which see), but are intended for overpowering or neutralising bad smells, especially those resulting from impurities, but they do not kill infectious germs.

Chlorine, chloride of zinc, nitrate of lead, and solutions of borax, are all employed for this purpose. Offensive matter may also be deprived of odour by burning acetic acid, vinegar, camphor, fragrant pastilles, cascarilla, brown paper, etc.; but they do not disinfect nor destroy contagion. These merely hide, cover, or disguise putrescent odour.

Derbyshire Cheese. — A small, white, and rich buttery variety, like Dunlop cheese, and made in very much the same way as Cheddar and Cheshire, but the salt is applied externally.

It mostly goes to the London market. One variety is shaped like Gouda cheese, and known as "Derby Goudas."

These latter were first made at a factory started by the Duke of Devonshire at Derby and Longford in the sixties.

Desiccated Coker (or Cocoa) Nut. —The white fleshy part of the coker-nut (sometimes spelt koker), *Cocos nucifera*, sliced or ground, and deprived of all humidity by evaporation.

The nuts are first broken and the kernels removed, and then passed to a peeling machine, where the skins are taken neatly off. The skinned nuts are next washed in barrels, and are cut or shred according to the class of product required. If shred, the mass is dried thoroughly in hot revolving pans, and thus acquires its desiccated condition.

It arrives from Ceylon and the United States in lead-lined cases of about 1 cwt. each.

The whiter it is the better; the yellow or brownish is considered discoloured, and brings a lower price, although for many uses it is quite as good.

It is sold sweetened and unsweetened; present value, 30/- to 35/- per cwt., according to grade. Grocers and confectioners should buy it unsweetened, and add the sugar themselves if necessary, sugar being only about half the price of the coker-nut.

Special Manufacturers.—M. E. Holdsworth, 3 Norfolk Street, Bradford; John May, 114 Church Street, Croydon, makes large handsome packets to sell at 4½d.; J. H. Vavasseur & Co., 13 St. Swithin's Lane, London, E.C.

Desiccated Fruits. — See *Evaporated* or *Dried Fruits, Vegetables*, etc.

Detergents.—(See also *Deodorisers* and *Disinfectants.*)—These consist of lotions, ointments, powders, and medicinal preparations for cleansing or purging away offensive matters, either internal or external.

Devilled Ham, etc. — "Devilled" means boiled, and highly seasoned with hot spices, such as mustard, pepper, cayenne, etc.

Hence we have devilled chicken, turkey, etc., etc.

Devonshire Cider.—See *Cider.*

Devonshire Clotted Cream.—See *Clotted Cream.*

Devonshire White Ale.—(See also *Ales.*)—This curious beer was invented at Plymouth about the year 1680. There being at that time very few cellars in that town on account of its stony foundation, it was generally fermented or worked in the back premises of the publican. The fermenting stuff was a secret preparation, called "Ripening" by its vendors, but was supposed to be a mixture of malt, flour, yeast, and white of egg. A lump of this converted the wort from a very clear body into a thick fermenting one, looking and tasting like milk. A barrel is, however, easily prepared by slowly boiling pale ale-wort with 6 ozs. hops and 12lbs. crushed oats. The liquor, when strained and cooled to about 60° F., is fermented by the addition of two good pints of yeast, and as soon as the fermentation is at its height, the liquor is bunged up in casks, or bottled and wired.

This ale is now drunk only in some parts of that county.

Dewberries.—See *Brambles.*

Dextrine or **British Gum.**—G. *Stärkegummi*; It. and Sp. *Destrina.*

(Also known as *Alsace*, *Artificial*, or *Starch Gum.*)

A gum-like substance, mostly obtained from potatoes or potato starch, but also from wheat and maize, by roasting these until they become brown, and mixing with weak nitric acid.

It is easily produced by heating to the temperature of 320° F. starch which has been moistened with a small quantity of nitric acid. (A further fermentation of this starch would turn it into glucose.)

Dextrine is soluble in cold water, and besides being employed as a stiffening substance by calico printers, crape and muslin manufacturers, etc., in lieu of the more expensive natural gums, it is extensively used on postage and revenue stamps, envelopes, etc.

Postage stamp gum may be prepared as follows:—4 ozs. dextrine, 7 fluid ozs. water, 1 oz. acetic acid, and 1 oz. alcohol. Add the acetic acid to the water, bring to a boil, and then dissolve in it the dextrine. Remove the vessel from the fire, and, when cool, pour in the alcohol. A little glycerine is also often used, to prevent the paper curling.

Dextrose is a hard grape sugar, a solid product first discovered in grapes by Lowitz in 1792, hence its name of *grape sugar;* then in 1811 a similar kind, but softer, was found also in starch by Kirchoff, and this was called *starch sugar*, or glucose; and in 1819 Bracounot was able to prepare another from woody fibre.

This saccharine substance is easily obtained by the conversion of farinas or starches into a semi-fluid state by extreme heat and the action of acids, vitriol, etc.

The actual saccharine or sweetening property is really the same whether obtained from grapes and other fruits, grain or starch, potatoes, wood or sawdust, or cotton or linen rags; for they all contain the elements necessary—carbon, oxygen, and hydrogen—the proportions only requiring to be chemically adjusted by acids.

In its hard state it is called dextrose, or grape sugar; and glucose, or starch sugar, when soft.

Dhal.—A name in India for Pigeon peas (*Cajanus Indicus*), one of the best and most nourishing of Indian pulses. It is eaten in various ways, but is most popular as a sort of thick pea-soup poured over boiled rice.

Dhurra, Dourrah, or **Durra**—See *Dari* and *Millet Seed.*

Diatomite.—See *Kieselguhr.*

Digby Chicks.—A conventional name for the smoked herrings cured and exported from the town of Digby, in Nova Scotia, Canada. A large amount of business is also done at Digby in Finnan Haddies, Lobsters, and Dulse.

Dika or Odika Bread.—F. *Pain de dika* (sometimes called *Gaboon Chocolate*).

This is made in the West African forests from the seeds (*oba*) of the ibo tree (*Irvingia Carteri*). The plums are gathered, as they fall from the tree, into large heaps, where they remain until the outside has putrefied; then the stones are cracked, and the kernels or almonds taken out and smoked for some days. Next they are put into a large mortar to be crushed and agglomerated into a homogeneous mass, weighing 10 or 12lbs. This is exposed to the rays of the sun, which causes the fatty portion (like *Cacao butter*) to melt and separate. It is somewhat darker in colour than Palm oil and of about the same consistence. The flavour resembles that of cocoa, and it is very suitable for confectionery purposes. Dika is generally moulded into cakes; it will keep good for six months, and the natives of the Cameroons eat it as a flavouring ingredient. (See also *Owala-seed.*)

Dill.—*Dill-Seed.*—F. *Fruits d'Aneth;* G. *Dillenfrüchte.*

The seed or fruit of *Anethum graveolens*, or garden dill. It is used by the Cossacks as a condiment, and in England it is sometimes employed to heighten the flavour of soups and pickles, especially cucumbers.

The English and Indian dill fruits are the growths usually met with in this

country, and the German is exactly like the English, the two mericarps being usually separated from the pedical, each of them being oval and about ⅛ inch long and ⅛ to 1·10 inch broad, a decided brown in colour, the dorsal ridges being inconspicuous, but the lateral much prolonged into the form of wings. In the Indian, which is mostly used, those lateral ridges are not so prolonged, and the colour of the fruits is a paler brown, the mericarps being usually not divided. The English is richest in oil.

Dill-water is a favourite remedy of nurses to promote the secretion of milk, and to relieve flatulence and griping in infants.

Dingaan Apricots.—See *Apples.*

Dip Candles.—(See also *Candles.*)—Tallow *dips* were originally introduced as an improvement upon the simple *rush-light.* The wicks, made of loosely twisted cotton yarn, are stretched separately in a frame made to hold several wicks, and when these are all attached, the frame is simply *dipped* three or four times into a trough, or vat, of melted tallow, and then left to harden.

After repeating the process a few times the candles assume the requisite thickness, which is usually determined by weighing, but "a dozen of dips" seldom weighs more than about 11½lbs.

The chief objection to "dips" is—(1) The low melting point of the tallow and its oily nature; (2) the irritating fumes produced, and which are due to the glycerine in the tallow being decomposed and yielding acrolein. Dips have now been largely superseded by *Mould* candles.

Disinfectants. — F. *Desinfectants;* G. *Desinficirungs-mittel;* It. *Disinfettanti;* Sp. *Desinfectantes.* (See also *Antiseptics, Deodorisers,* and *Detergents.*)

Preparations intended to absorb, neutralise, destroy, or remove the contagion or germs of infectious diseases, offensive, fœtid, or putrescent effluvia, miasmata, or other specific contagia. They comprise:—

(1) Volatile Gases or Vapours, such as oxygen, ozone, chlorines, bromines, iodines, and other halogens; also the fumes of sulphur, nitre, camphor, hop-oil, rue, rosemary, camomile, etc.

(2) Liquids and Solids—All soluble chlorides, sulphates, sulphites, some acetates (iron, etc.), some nitrates (potash, soda, etc.), strong acids, and alkaline solutions.

The principal disinfectants consist of chlorides of lime, soda, and zinc, carbolic acid, peat charcoal, mercuric chloride, heat, sulphur dioxide, iron protosulphate, etc.

A disinfectant may be also a deodorant, but it is not every deodorant that is a disinfectant. It does not suffice that a disinfectant should possess a pleasant odour, powerful enough to disguise, overcome, or neutralise a noxious odour, but it should be an actual germicide, destroying the germs that give rise to the bad smell.

Chlorines and soda preparations with ventilation are considered best for disinfecting the air. A good and cheap one is made by dissolving half a drachm of nitrate of lead in a pint of boiling water, then dissolve two drachms of common salt in eight or ten quarts of water. When both are thoroughly dissolved pour them together, and when the sediment has settled there is a pail of clear fluid, which is the saturated solution of chloride of lead. A cloth saturated with this liquid and hung up in a room will at once sweeten a fetid atmosphere; poured down a sink, water-closet, or drain, or on any decaying or offensive object, it will produce the same result. The nitrate of lead is very cheap, and a pound of it will make several barrels of the disinfectant.

Steam or stove heat is often used for dirty clothes in some of our workhouses and hospitals. Quick-lime or whiting are useful for covering walls; sulphates of iron or lime, chloride of lime or soda for cesspools.

Dr. W. Burnett's Disinfecting Fluid seems like a neutral solution of zinc in commercial muriatic acid.

Sanitas is largely produced from Russian turpentine.

Collins's Disinfecting Powder is thought to be composed of two parts of dry chloride of lime with one part of burnt alum, and is used with or without water to purify rooms, cesspools, etc.

Douglas's Disinfecting Powder is said to be sulphate of calcium mixed with chalk and carbolic acid.

Another kind is made from, say, 40 ozs. freshly slaked carbonate of lime, 2 ozs. marble dust or fine sand, and 3 drachms of carbolic acid crystals. The acid and dust or sand are first mixed together, and then with the other ingredients.

Special Firms.—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; F. Newbery & Sons, 27 and 28 Charterhouse Square, London, E.C.; Paton, Calvert & Co., Leeds Street, Liverpool (see *Paton's "Cleanall" Powder*).

Distemper or **Destemper.**—Colours ground up with size, gum, or white of egg, and water. (See also *Water Paints.*) Used for scene painting, also for colouring walls, woodwork, etc.

Distilled Vinegar.—(See also *Vinegar.*)—Distilled vinegar is commonly manufactured from ordinary brown vinegar, by subjecting the latter to the process of distillation. Earthenware stills, heated by steam jackets, are largely employed for this purpose. The water, acetic acid, and other volatile and flavouring bodies throw over, and are condensed in coiled tubes lying in water. The vinegar thus obtained is water-white and perfectly clear. It usually lacks flavour, and, if the distillation be carried too far, acquires an unpleasant odour and taste. The distilled vinegar is also somewhat weaker than the original vinegar used in the still. Distilled vinegar is free from nitrogen, sugar, and solid bodies. It is sometimes produced from "white wine vinegar," and is then of whiter colour.

But much of the "distilled vinegar" sold by druggists is merely acetic acid and water. There is really no fixed standard as to what vinegar itself should consist of.

Turner's "Chemistry," 4th edition, 1833, says: "The distilled vinegar which is now generally employed for chemical purposes is prepared by the distillation of wood."

Tomlinson's Cyclopædia (1854) says: "A pure variety, called 'distilled vinegar,' was formerly produced by distilling common vinegar, a plan now almost entirely superseded by mixing pure acetic acid with water."

In *Roscoe and Schorlemmer's "Treatise on Chemistry,"* vol. 3, page 484, the authors say: "Glauber in 1648 states that acetic acid is '*acetum lignorum,*'" and "by rectification it may be made as good as '*acetum vini.*'"

Durande, in 1777, also calls strong acetic acid "vinaigre glacial."

Food inspectors and some analysts have lately sought to restrict the term vinegar according to their own ideas, and that in a very illogical way, for it is very difficult to affix a strict scientific definition to a name which has so long been in use to cover such a varied ground as the word "vinegar."

Ditalini.—A variety of Italian paste in the form of thick pipes, cut diagonally, two to four inches long, and often artificially coloured yellow. (See *Italian Paste.*)

Divi-divi, or **Libi-dibi.**—The native and commercial name for the pods of the South American plant *Cæsalpinia coriaria.* The pods as imported are about two inches long by three-quarters of an inch broad, of a brownish colour, and curled up like some pea-pods.

The seeds seem valueless, but the husk contains a bright yellow resin of remarkable astringency, and of great use in tanning. Immense quantities grow wild in the Rio Hacha Plain, Bogota, Colombia. Some 4,000 tons are gathered and exported, but as many more are left on the ground to rot.

Dodder Cake.—A kind of oil-cake or cattle food, manufactured in Lübeck from the *marc* or skins of the seed of the *Camelina sativa.*

Dog Biscuits.—The principal ingredients are animal offal and other refuse.

Dog Soaps.—Generally made by mixing Stockholm tar with ordinary melted soap, the tar being first dissolved in wood naphtha.

Dogwood Oil.—An oil obtained from the berries of *Cornus sanguinea*, in certain parts of Europe and Asia.

Useful for lamps, soaps, etc., and when properly refined, for culinary purposes.

Doncaster Butter Scotch.—A superior kind of pale brown toffee, generally made by boiling over a slow fire the following or similar proportions:—Say 6lbs. best cane sugar in a pint of water and ½ oz. cream of tartar; when it comes to the boil 2lbs. of butter are added, and the boiling continued until enough.

This is known by dipping a knife or steel—first into the boiling sugar and then into cold water; if the sugar which adheres to the steel is *crisp* and can be crunched without sticking much to the teeth, it is done; but if it be soft and sticky it wants boiling longer.

When enough, it is poured into small moulds, well greased with butter or slab-oil, and afterwards, when cold, it may be turned out, wrapped in wax-paper, tin-foil, or otherwise kept as near air-tight as possible.

Doodoe Nuts.—See *Candle Nuts.*

Doorn Tea.—An African beverage, having emollient and expectorant qualities, and is made from the leaves of *Cliffortia ilicifolia.*

Doppel Kummel.—See *Kummel.*

Dorsetshire or **Blue Veiny Cheese**—So called from its blue-veined appearance. It is made entirely from skimmed milk and not so rich, but otherwise compares well with *Stilton.*

Draff.—See *Brewers' Grains.*

Dragees or **Sugared Almonds.**—(See also *Comfits.*)—French sweetmeats, consisting of almonds or filbert kernels covered with a thin coating of white or coloured sugar. Dragée is French for sugared almond, carvie, bonbon, comfit, sugar-plum, or other sweet, formed and enlarged by gradual additions of syrup baked. They are usually made round, oval, or long, and the colours are various and sometimes overlaid on each other. The noyau, or centre of the dragée proper, is formed by an almond, carvie, caraway seed, pistache, or other nut or fruit instead.

One kind, *Dragées à liqueur*, contains perfumed spirit enclosed in starch and gummed.

Dragées avelines contain the kernels of filberts instead of almonds. Whatever the noyau or centre is composed of, the dragées are coated with flavoured sugar, ladled in a syrupy state in an open pan, worked by hand over the stove, or in a revolving steam-jacketed pan, each ladleful being well dried on before another is added. In making the smaller size of dragées the syrup is added through a sort of jet syringe or continuing jet, the operation being continued until the dragées are considered large enough.

Verdum is a noted centre of manufacture.

Dragées are as popular at christenings in France as is rice at weddings in England, and are strewn about at the church door in similar profusion.

Dragon's Blood.—Da. *Dragoblod*; F. *Sang-dragon*; G. *Drachenblut*; Lat. *Draconis resina*; Port. *Sangue de draco*; Sp. *Sangre de dragon.*

A name given to the deep red resins of a Malayan Ratan Palm (*Dæmonorops draco*), and several other kinds of Eucalyptus trees and plants of the Pterocarpus order, as well as to that exuding from the East Indian palm *Calamus draco.* It is said to owe its name to the supposed similitude of the bayonet-like leaves, scaly fruit or the kernels themselves, to the conventional reptile as figured at Temple Bar, for no one quite knows what a dragon was.

The resin is obtained by shaking the fruits in a sieve or sack and then moulding the powdery product into lumps by heat.

Mostly imported from Sumatra and Borneo, and largely used in oils, turpentines, and varnishes for staining marble, leather, wool, etc., and for colouring dentifrices, plasters, etc. Its colour, in "tears" or masses, is a dark brownish red; in powder, bright red. It is very friable, and breaks with a shining fracture. When pure it readily dissolves in alcohol, ether, and oils, yielding rich red solutions. There are adulterated and fictitious kinds.

Dried Beef. —See *Charqui.*

Dried Apples.— See *Apples* and *Apple Rings*, also *Evaporated Fruits.*

Dried Fruit.—This term comprises Almonds, Currants, Dates, Evaporated Fruits, Figs, Imperials, Plums, Prunes, and Raisins, each kind of which is fully described under its respective name.

They are always sold at actual landing weights, gross and tare.

Liverpool is now the centre of the Dried Fruit trade of the United Kingdom.

Fruits are too often gathered and dried before being ripe, hence the flavour is very inferior to that of fruit well ripened on the tree.

In the western part of the State of New York something like 1,500 tons of fruit alone are dried in evaporators, the greater portion of which is sold for domestic use in the U.S.

From Australia and Canada large quantities are now annually imported into the U.K.

The first fruit-drying machines were invented in America in 1867.

Fruit Exporters.—Messrs. M. & W. Jones, Villa Nova de Gaya, Portugal.

Dried Herbs. — F. *Chiffonnade;* G. *Gezupfte Suppenkräuter.*

Aromatic herbs have always been considered very valuable for their stimulating and antiseptic properties, as well as for their agreeable aroma and pungent flavour. Of course, they are at their best when plucked fresh. The best time to gather them for drying and bottling is on a dry day in the height of the season, just before they begin to flower; they are then full of juice and in greatest perfection. They should be cleansed from insects, earth, and dust, as well as from all rotten and discoloured leaves. A common practice is to hang them up in bunches or paper bags till wanted; but the best and cleanest way is to pick off the leaves, dry them before the fire, reduce them to powder, and cork up in clean dry bottles. The quicker they are dried the better, as they have less time to ferment or grow mouldy; a better aroma is also thus secured.

An excellent aromatic seasoning of herbs and spices is prepared as follows:—Take 1½ ozs. of thyme, 1 oz. of bay-leaves, 1 oz. of savoury, 1 oz. of basil, and 1½ ozs. of marjoram. Dry them thoroughly, pick the leaves. Pound in a morter ¼ oz. of cayenne pepper, with 1 oz. of peppercorns, 1 oz. of cloves, a clove of garlic, the thinly-peeled rind of a lemon, ½ oz. of mace, and 1 nutmeg grated. Mix all well together, pass them through a sieve, and keep stored in well-corked bottles. Time to prepare, one hour and a-half. Probable cost, 1s. 6d. for a pint bottle.

Basil is best gathered about middle of August; *Burnet*, June, July, and August; *Chervil*, May, June, and July; *Fennel*, May, June, and July; *Knotted Marjoram*, July, value 46/- per cwt.; *Mint*, July, value 75/- per cwt.; *Parsley*, May, June, and July; *Sage*, August and September, 22/6 per cwt.; *Savoury*, end of July and August, 15s. per cwt.; *Tarragon*, June, July, and August; *Thyme*, end of July and August, 14/- per cwt.

Dried Mushrooms.—Usually sold in bales of about 1½ cwt. Strong aroma, and generally about 90/- cwt. It is important to know whether they

are free from poisonous varieties. (See *Mushrooms*.)

Dried Plums. See *Bosnian Plums, Prunes*, etc.)

Dried Turtle.—(See also *Turtle Meat and Turtle Soup*.)—Sun-dried turtle is mostly imported from the West Indies, and is usually retailed at 4/6 to 7/6 per lb. It is never eaten alone, but is made into soup. Soup for a dozen or more persons may be made from a quarter of a pound of dried turtle.

It is not generally known that the ordinary land tortoise is excellent eating, and in the West Indies it frequently finds its ways into soups and pies.

Driers.— These are substances incorporated with oils, to facilitate the drying of paints by increasing their power of absorbing the oxygen of the air. They are prepared from various sources. Those in highest repute appear to be the oxides and other compounds of lead and manganese.

1. For dark colours: Best Litharge, ground to a paste with boiled linseed oil.

2. For pale colours: White Copperas and drying oil as above.

3. From Sugar of Lead and drying oil.

4. A drying property may be imparted to linseed oil by boiling it with drying substances, and it thus becomes a very useful vehicle for paints.

Drugs and Sundries.—Herbs or plants containing drugs have been used from the earliest times, and the knowledge of the virtues of each has generally been acquired by accident. Many of the common remedies have long been sold by grocers and general shopkeepers in the smaller towns and villages throughout the country, and during the last twenty years most of the larger stores have been stocking a much extended list. The number of self-doctoring people seems to increase. An ordinary shopkeeper may sell certain remedies when asked for them, but no prudent man, ignorant of diseases and medicines, will undertake prescribing remedies. It is illegal for an unregistered person to act as an "apothecary," but what the latter really means is not very clearly known to everybody, so it may be explained that a duly qualified pharmaceutical chemist is one who sells medicines which are asked for. An apothecary is one who himself selects the medicines and determines on what he ought to give. A man may know that inoculation with vaccine lymph prevents small-pox; that lime juice prevents scurvey; that opium relieves pain; that salicylate of soda cures rheumatic fever; that quinine cures malaria; that iron cures bloodlessness or anæmia; and that a great number of other specifics relieve certain diseases; but the efficacy of a remedy depends much upon the time it is taken and the condition of the person. He may have heard that bismuth stops vomiting, but to give it in a case of strangulated rupture would certainly endanger life; so also to give croton oil as a powerful purgative to one suffering from constipation due to inflammation, might cause death. A dose of chlorodyne, for instance, will relieve a stomach-ache if it fits the complaint, but will not effect a cure where a dose of castor oil or an aperient is necessary. Then as to *doses*, different constitutions require different quantities, and the vendor must make himself correctly acquainted with the *Apothecaries' table*. He must learn what a tablespoonful means, for the modern tablespoon more often contains 6 drachms than 4 drachms. Much also depends on the strength or quality of the drug taken, and whether there is to be a single or repeated administration of the medicine. The habit or desire for taking some drugs—such as opium, morphia, antipyrine, arsenic, and even sulfonal (easily acquired, and as bad to get rid of as the craving for alcohol)—enables some persons to take doses which would kill others. How-

ever, as only registered chemists are allowed to sell medicines which contain such poisons, it has only been thought useful here to append a description of the articles which can be sold by anybody, and to give a few hints as to ordinary uses and doses. Many of the articles are more fully described in the alphabetical order of the book.

Purgatives act best if taken first thing in the morning, when the stomach is empty. Cod-liver oil can be taken in far larger doses in cold weather than in hot.

Gargles.—Children are unable to gargle properly, so that if necessary the back part of the throat is usually treated with the tincture of perchloride or iron, and applied with a camel-hair brush.

The following table for proportioning the doses of medicines to the age of the patient was originally drawn up by Gaubius:—

Under ½	year—	1/18	of a full dose.
,, 1	,,	1/12	,,
,, 2	,,	1/8	,,
,, 3	,,	1/6	,,
,, 4	,,	1/5	,,
,, 7	,,	1/3	,,
,, 14	,,	1/2	,,
,, 20	,,	2/3	,,
Above 21	years,	the full	dose.
,, 63	,,	11/12	,,
,, 77	,,	5/6	,,
,, 100	,,	2/3	,,

Dr. Young gives the following simple guide:—For children under 12 the doses of most medicines must be diminished in proportion of the age to the age increased by 12 years. Thus, at two years the dose should be 1-7th of that for an adult, viz., $\frac{2}{2+12} = \frac{1}{7}$.

Alum.—This is useful as a gargle and an astringent for inflammation of gums. Invaluable in dyeing (see p. 37).

Amber (*Oil of*).—Stimulant, antispasmodic, and diuretic. Given for dropsy, etc. Dose 5 to 10 drops. Externally as a rubefacient for paralytic and rheumatic limbs.

Ammonia is used in lump or liquid for cleaning clothes and for washing utensils.

Ammonia, Aromatic Spirit of (Spirits of Sal Volatile).—Stimulant, antispasmodic, diaphoretic. Given for syncope, paralysis, nervous weakness. Dose 10 to 30 drops. For faintness a teaspoonful in a wineglassful of water.

Aniseed Water.—Given to babies as a carminative; also good in cough mixtures for children. The *oil* is used to bait rat-traps, 3 or 4 drops being quite sufficient (see page 46).

Antibilious Pills.—Aperient and good for biliousness. Dose, 2 at bedtime.

Aromatic Vinegar.—Used as a smelling-bottle for headache or fainting (see page 56).

Asafœtida.—In the form of a four-grain pill often given for flatulency, colic, etc.

Barley (*Robinson's Prepared*).—Emollient, nutritive. Excellent food for infants.

Basilicon Ointment.—Drawing, emollient, and healing.

Bitter-sweet.—Given for asthma, rheumatism, and scrofula. Dose, 10 to 30 grains.

Boracic Acid.—A teaspoonful dissolved in half a pint of warm water makes a very simple mouthwash. A little peppermint or lavender oil makes it pleasanter.

Boracic Ointment.—Cooling and healing.

Borax (in lump or powder).—A most useful medicine for many purposes. Mixed with honey for inflamed gums and sore mouths of infants. A splendid mouthwash for adults suffering from foul stomachs, and good gargle for sore throats. Also taken internally as a diuretic. Dose, 10 to 30 grains. Pure borax is an antidote for prickly heat and other inflammatory skin affections due to humid and hot weather. It is also used in laundries for washing purposes and for starching linen. Largely used by plumbers in soldering (see page 125).

Broom Tops.—The infusion is given

in dropsy as a diuretic.

Buckthorn Syrup.—Purgative. Equal parts of syrup and castor oil, given to dogs and cats.

Buchu Leaves.—Tonic, sudorific, diaphoretic. Given chiefly in retention of Urine or chronic inflammation of the bladder. Dose, 20 to 60 grains.

Calumbe Root.—Infused in hot water will make a good bitter stomachic and appetiser. A wineglassful to be taken twice a day.

Camphor (see page 166).—One of the most useful of domestic medicines. Preventative of disease; preserves clothes from moths and other insects. Mixed with chalk (powdered) forms a splendid tooth-powder.

Camphorated Oil.—See page 167.

Carbonate of Soda.—Given for indigestion, fermentation, and puffiness, or acidity of the stomach. Dose, 10 to 20 grains, in a cup of water. Also used as a baking powder.

Cardamom Seeds.—Stimulant, carminative, and stomachic tincture. Dose, 5 to 20 grains. Used in some countries for making cakes, etc.

Carraway Seeds.—Used for flatulency, dyspepsia, etc. Dose, 10 to 30 grains.

Carron Oil.—A mixture of linseed oil and lime water in equal quantities, for burns and scalds.

Cascarilla Bark.—A tonic, astringent and stomachic. Given in dyspepsia, flatulent colic. Dose, 20 to 60 grains. The bark, if lighted, emits a pleasant smell.

Castor Oil.—As a purgative, in its general use this acts more quickly than any other medicine, and seldom gripes. An aperient, best taken in warm milk or coffee. Child dose, ½ oz.; adult, 1 oz. It is also excellent for softening shoe leather, preserving the leather, and keeping out dampness.

Cayenne Pepper.—A tincture given for diarrhœa, dyspepsia, and flatulency. Dose, 5 to 10 grains. A few drops in a little water form an excellent gargle for inflamed throat.

Camomile Flowers (see page 205).—Infused in hot water; about a wineglassful taken before meals creates an appetite. With a little ginger, or any other aromatic, forms a splendid mixture for dyspepsia. With alkalies, for gout or derangement of the stomach. Also useful as a fomentation in swelling of the face, etc.

Cherry Ripe Powders.—See page 216.

Chlorate of Potash.—Diuretic and stimulant. Useful as a gargle in ulceration of the throat. Dose 5 to 30 grains.

Chloride of Soda (Common salt).—Given for worms, vomiting of blood; also used as a tooth-powder, and in solution as a mouthwash.

Cinchona Bark.—Bitter, astringent, and tonic; given as a substitute for quinine. Dose, 10 to 30 grains.

Cinnamon Bark.—Most grateful aromatic; given in dyspepsia and diarrhœa. Dose, 10 to 30 grains.

Citric Acid.—Antiseptic and refrigerant; useful as a refreshing drink, like lemonade, etc., in fevers, or when the mouth is parched and dry. Dose, 10 to 60 grains, in water.

Cloves.—Stomachic and stimulant. Dose, 5 to 10 grains. The oil is good for toothache.

Common Fennel.—Carminative and diuretic. Dose, 10 to 30 grains.

Compound Rhubarb Pills.—Gentle aperient, for indigestion. Dose, 2 at bedtime or 1 before food.

Compound Liquorice Powder.—Aperient and stomachic. Dose, 1 teaspoonful at bedtime.

Cream of Tartar.—Refrigerant, diuretic, slightly aperient. Given in habitual constipation. Also made into drinks for persons labouring under febrile and inflammatory affections. Dose, ½ to 1 teaspoonful. It is one of the most useful of domestic medicines.

Dandelion Decoction (concentrated).—Diuretic and aperient. Given in dropsy, inflamation, jaundice, and in liver and kidney diseases. Dose, 1 to 2 teaspoonfuls.

Dill Water.—Carminative. Given to babies for wind. Dose 1 or 2 teaspoonfuls.

Elder Flowers.—The water has an agreeable odour, and is used as a wash for the face. The ointment is very pleasant and cool.

Elm Bark.—In powder, used as a poultice for drawing abscesses.

Epsom Salts.—Purgative and diuretic. Dose, ½ to 1 oz. Well diluted, is a good blood purifier and cleansing medicine for the stomach.

Essence or Spirits of Camphor.—Stimulant, antispasmodic. Recommended in diarrhœa or bowel complaints. A good preventative of cold. Dose, 10 drops on sugar. Mixed with ammonia and turpentine forms a splendid liniment for rheumatism, sprains, or bruises.

Essence or Spirits of Peppermint.—Stimulant, carminative, cordial, stomachic. 10 drops on sugar or in a teaspoonful of water.

Figs.—Demulcent, and slightly laxative.

Fryar's Balsam (compound tincture of benzoin.)—Used in cases of chronic cough, irritation of the throat. Externally applied to rough, ragged, and bleeding cuts. Dose, 20 drops on lump sugar, but will not mix with water. The household should never be without it.

Foot Powder for sweaty feet and bad odour of the feet. 21 parts of powdered alum mixed with 1 part of maize meal.

Gambia.—When chewed in the mouth is useful in cases of severe purging.

Gentian Root.—Tonic, stomachic, slightly aperient. Given in dyspepsia, debility, hysteria, gout, jaundice, etc. Dose, 10 to 30 grains.

Ginger Essence or *Tincture.*—Carminative, stimulant. Given in conjunction with other remedies in dyspepsia, flatulency. Dose, 10 drops on sugar or in a teaspoonful of water.

Ginger Root.—Carminative, stimulant, and good for flatulency; also useful as a sialagogue, a little chewed before dinner promoting the flow of saliva.

Glauber's Salts (*Sulphate of Soda*).—Purgative. Dose, ½ to 1 oz. Given in small doses as a purifier for the stomach. Often taken in the place of Epsom salts.

Goose-Grease (*Adeps Anseris*).—One of the most useful emollients known, and, when applied to the surface of the skin, penetrates more thoroughly than any other fat or oil.

Gregory's Powders.—See separate heading.

Guaicum Tincture (*Compound*).—Stimulant, diaphoretic. Good for rheumatism or gout. One teaspoonful in a little milk.

Hops.—A narcotic, anodyne, and a tonic. Dose 5 to 10 grains. A pillow of hops will induce sleep.

Hop Tincture.—Bitter, stomachic. Given for a loss of appetite. Dose, ½ to 2 teaspoonfuls.

Horehound.—Given in chronic catarrh and asthma. Dose in powder, half a teaspoonful.

Iceland Moss.—Given in asthma and bronchitis. Dose, 1 to 4 drachms.

Indigestion Powders.—For acid dyspepsia a simple mixture of bicarbonate of soda and ginger is often given. It may be flavoured with a trace of spear mint or peppermint. In other cases, American scale pepsin 5 grains and powdered ginger 5 grains form a common dose.

Iodide of Potash.—Given in rheumatic gout. Also as a blood purifier. Dose, 2 to 5 grains.

Iodide of Iron Syrup.—Tonic, alterative. Used in scrofulous affections and in chronic rheumatism. Dose, ½ to 1 teaspoonful in water.

Ipecacuanha Wine.—Emetic, expectorant. Given for cough and cold. Dose, 10 to 20 drops. As an emetic 2 tablespoonfuls.

Irish Moss.—Given in asthma and bronchitis. Dose, 1 to 4 drachms.

Iron Wine.—Tonic. Strengthening, given with cod-liver oil for delicate children. Dose, 1 to 2 teaspoonfuls.

Juniper (*Oil of*).—Stimulant, carminative, and diuretic. Good for pain

in back. Dose 5 to 10 drops.

Lavender Tincture Compound.—For lowness of spirits or hysteria. Dose, ½ to 2 teaspoonfuls.

Lime Water.—Antacid, astringent. Given in diarrhœa. (Should contain 1 gramme of lime in 2 ozs. of water.)

Lime Water, Mixed with Linseed Oil (Carron Oil) applied the first thing for burns and scalds.

Linseed.—In infusion it forms a very serviceable, demulcent, and mucilaginous drink for cough.

Liquorice Root.—Demulcent. Given in asthma and bronchitis.

Logwood.—Tonic; recommended in chronic diarrhœa and dysentery. Chiefly used in dyeing.

Magnesia (*Calcined*, or *Carbonate of*).—Antacid and laxative. Used in heartburn; very cooling and cleansing for the stomach. Dose, ½ to 1 teaspoonful.

Manna.—Commonly given as a laxative to children.

Marshmallow Flowers or *Roots.*—A favourite medicine among Spaniards. Demulcent, lubricant, emollient. Used in pulmonary and intestinal affections; also a gargle and for fomentations.

Marshmallow Ointment.—Drawing, emollient, and healing.

Mulberries.—Delicious, cooling, and laxative.

Myrrh.—Tonic, emmenagogue, stimulant, and expectorant. Dose, 10 to 30 grains. Used in almost all tooth-powders.

Myrrh Tincture.—Seldom used alone, but with a little alum and water is a pleasant and good astringent for relaxed and inflamed gums.

Nitre or *Saltpetre.*—Diuretic and refrigerant. Dose, 5 to 10 grains. Given for sore throats and in cases of fevers. It is also useful in teaspoonful doses for horses.

Nut Gall Ointment.—Astringent; useful for piles.

Nutmeg.—Carminative. Given for dyspepsia and nausea. Dose, 5 to 10 grains.

Olive Oil.—Demulcent, laxative, and relaxant. Given for catarrh, pulmonary disorder, and worms. Dose, 2 teaspoonfuls.

Orange Tincture.—Tonic and stomachic. Dose, 1 to 2 teaspoonfuls.

Oxide of Lime (Zinc Powder).—Used as a face powder. Recommended for healing sores or abrasion of the skin.

Pellitory of Spain (Pyrethrum Root).—Stimulant and sialagogue. The tincture is good for toothache.

Peppermint.—Carminative and spasmodic.

Pimento.—A spice, stimulant, tonic, and carminative. Dose, 10 to 20 grains.

Pomegranate.—Given in diarrhœa. Useful as a gargle for quinsy; also good for worms. Dose, 10 to 30 grains.

Potash (*Bi-carbonate of*).—Antacid and diuretic. Given in sickness or vomiting. In cough mixture as a stimulant and expectorant. Dose, 10 to 20 grains.

Prunes.—Laxative and nutritive.

Quassia Chips.—A splendid tonic, and will create a good appetite; a substitute for quinine. A weak infusion, if applied to children's hair, destroys nits.

Quinine Sulphate.—Tonic and febrifuge. The properties are known to nearly everyone. Dose, 3 to 5 grains. (Also known as *Ague salt*, *Jesuits' powder*, etc.)

Quinine Tincture.—Tonic given in cases of neuralgia, nervousness, etc. Ammoniated tincture of quinine is used in influenza, cold—especially for cold in the head. Dose, 1 teaspoonful in a wineglassful of water.

Resin, or *Basilicon Ointment.*—Applied to indolent and ill-conditioned ulcers, etc.

Rhatany.—Given in diarrhœa, hemorrhages, etc. Dose, 5 to 15 grains. The tincture in water is an astringent for relaxed gums.

Rhubarb (root or powder).—Astringent and purgative. Dose 5 to 30 grains. A small piece chewed in the mouth will relieve indigestion.

Rhubarb Tincture.—Stomachic. Dose, 2 teaspoonfuls. Purgative (1 oz.), 2 teaspoonfuls used in colic and diarrhœa.

Rosemary.—Useful as a hair-wash.

Roses (Confection of).—If applied to the eyes will relieve any irritation.

Rose Water.—Fragrant. Mixed with glycerine is useful for rough hands and face.

Rue.—Stimulant, antispasmodic, and emmenagogue. Given in hysteria and flatulent colic. Dose, 10 to 30 grains.

Saffron.—Used as a colouring. Sometimes given for measles, but very uncertain as a medicine.

Sal Ammoniac.—Used by plumbers for soldering. An excellent remedy for chilblains. Given also in asthma and bronchitis. Dose, 10 to 20 grains.

Salts of Tartar.—Used as a hair-wash.

Sassafras.—Given with sarsaparilla for purifying the blood.

Sarsaparilla Decoction.—A splendid blood purifier, alterative, demulcent, and slightly diaphoretic. Given chiefly in cutaneous affections.

Seidlitz Powders.—Aperient. For sickness and biliousness. Best taken before breakfast. (See also separate entry.)

Senega Root.—Stimulant, expectorant, and diuretic. Given in chronic catarrh, asthma, and bronchitis.

Senna.—Given for constipation, and especially to dropsical persons. Often given to children.

Senna Confection.—Lenitive, electuary, aperient, lavative; useful in habitual constipation. A very safe remedy. Dose, 1 or 2 teaspoonfuls.

Senna Syrup.—Purgative. Dose, 1 to 4 teaspoonfuls.

Senna Tincture Compound.—Stomachic, purgative. Dose, 1 to 4 teaspoonfuls.

Spermaceti.—Demulcent and emollient. Used in coughs and consumption. Dose, 20 to 60 grains.

Spermaceti Ointment.—A mild and softening cerate.

Spirits of Sweet Nitre.—Diuretic, diaphoretic, and refrigerant. Used in fevers, dropsy. Dose, 10 to 40 drops. For a severe cold 1 tablespoonful (2d. worth) in half a tumbler of warm water, add a lump of sugar, and taken at bedtime is very useful.

Spirits or *Oil of Turpentine.*—Purgative, stimulant, and rubefacient. Not often used internally except as an anthelmintic (worms). Dose, 8 to 10 drops on sugar to be taken fasting. It is the principal ingredient in most liniments or embrocations.

Venice turpentine is used for drawing abscesses, etc.

Starch Powder.—Used as a dusting or healing powder.

Steel Tincture or *Iron Tonic.*—Emmenagogue. Dose, 10 to 30 drops in water after food.

Sulphur or *Brimstone Flowers.*—Chiefly used as an alterative and laxative. Externally (in the form of ointment) and internally for itch and other cutaneous diseases. Dose, 1 teaspoonful in milk or water. Also used for fumigating bedrooms after infectious fevers, etc., and to exterminate bugs from same. Sulphur baths recommended for rheumatism; also for skin diseases.

Sulphur (Milk of).—Laxative and blood purifier. Dose, 1 teaspoonful. Best taken in milk and water before breakfast. A little puffed on the face at bedtime will remove pimples and freckles.

Sulphur Ointment.—For irritation of the skin, itch, etc.

Tannic Acid.—Astringent. Useful in relaxed throat, as a gargle; also used in dressing skins of animals.

Tartaric Acid.—Refrigerant and laxative. Given in fevers and inflammations. Mixed with a little carbonate of soda and syrup of lemons forms a very refreshing and cooling beverage. Dose, 10 to 20 grains.

Tolu Tincture.—Stimulant, expectorant. Dose, 15 to 30 drops.

Turmeric.—Supposed to be good for dyspepsia and diarrhœa. Dose, 10 to 30 grains, but seldom used as a medicine.

Zinc Ointment.—For cooling and healing.

Caution.—Retailers are too ready to trust wholesalers and travellers, and take for granted that the preparations

obtained are up to sample, and of the nature, substance, and quality required. Hundreds are being fined heavily for selling preparations below the standard of the current British Pharmacopœia. Even if of full Pharmacopœial strength and quality when received into stock (which is not always the case), many of them change if kept too long, or the strength may evaporate if bottles are opened frequently or stoppers be left out. Most of the wholesale dealers in Drugs and Druggists' Sundries make up their own; and it is seldom that the cheapest are reliable, for anybody can call himself a manufacturing chemist. The Pharmaceutical Society, who get the fines, are always employing spies to entrap grocers or their assistants into selling Patent Medicines, Sheep Dips, Weed Killers, or drugs which contain poisons or medicaments which are below the proper standard, and the local chemists are generally the informers. It is therefore of the highest importance to shopkeepers that they should buy their supplies of official strength from respectable and *qualified* chemists, for not half of the "manufacturing chemists" have ever passed an examination. No better firm can be named than that of F. Newbery & Sons, 27 Charterhouse Square, London.

Drying Oils.—See *Boiled Oils.*

Dry Soaps. — (See also *Soap Powders, Borax Soap Powders, Washing Powders, Extracts of Soap,* etc.)—These are usually intended as scouring agents or to soften hard water. They consist largely of carbonate of soda together with a little real soap, and frequently a large addition of water and common salt. The general method of manufacture is to melt scraps and chippings of ordinary pale soap, and to boil with soda crystals dissolved in their own water of crystallisation. When boiled down or evaporated sufficiently, it is let out of the pan into a cooling trough, and a quantity of soda ash and bicarbonate of soda crutched into it while cooling; after which it is allowed to set into a stiff paste, and finally dried, ground, and packeted for sale. Their value depends partly on the water in them, which varies from 25 to 60 per cent., and partly on the quantity of *real soap* in them, which varies from 1½ to 20 per cent. The remainder is mostly carbonate of soda and common salt; some of them may also contain sodium and potassium chlorates and sulphates, with occasionally traces of paraffin, camphor, essential oils, and other bodies added to impart disinfectant or other special properties to the powder.

Special Firms.—Job Day, Garden Street, Leeds, and 52 Fenchurch Street, London, E.C.; H. May & Co., Ltd. (manufacturers), Goodinge Road, Islington, London, N.; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool (also Sole Agents for the "Westminster" Paraffin Dry Soap and "Lawrence's Musk Paraffin").

Du Barry's Revalenta. — Red lentils ground to a fine powder.

Dubbin or Dubbing.—A preparation used by curriers, shoemakers, and others to dress and soften leather, and to render it waterproof. The repeated use of blackings which contain sulphuric acid has a tendency to burn or rot the leather, and dubbin then becomes a useful application.

It is generally made by boiling waste cuttings of sheep-skins in common cod-oil; but sometimes by boiling, say, 2lbs. black resin with 1lb. of tallow in a gallon of train or cod oil till of proper consistency.

An ordinary quality is made by melting 2lbs. paraffin wax and 2lbs. resin in 2lbs. naphthalene and 1lb. soft soap; 1 gallon of warmed paraffin oil is then stirred in, and sometimes a little colouring matter.

A useful dubbin for summer use when boots need to carry a polish is made of 2 parts of golden syrup, 5 of castor oil, and 3 of carnauba wax.

For special preparations, apply to Day & Martin, Ltd., London and Liverpool. (See adv. near end of book.)

Duinen-thee.—An African beverage, usually drunk for coughs and chest diseases. It is an infusion of the leaves of *Helichrysum auriculatum.*

Dugong.—A name in Australasia and the Indian Ocean for the *Halicore Dugong*, which is taken chiefly for the oil obtained from the blubber. The oil is claimed to be equal to cod-liver oil. The bone of the animal in fineness and hardness of grain, specific gravity, and appearance, approaches ivory, and the flesh is often potted and sold in shops as a delicacy.

Dulse, or *Dillesk* as it is called in Ireland, is a kind of purple or crimson sea-weed, *Rhodymenia palmata.*

It is to some extent used as food by the Scotch and Irish, but most in Canada and Iceland.

It is washed in fresh water, dried, and packed in casks for preservation.

Some eat it with fish and butter; others boil it in milk with a little rye-flour, but it is often eaten raw, and is considered a good tonic and stomachic. Sheep and cattle also eat dulse in its fresh state. In Kamtchatka a fermented liquor is also made from it.

Dulse is usually to be found between tide-marks and deeper waters, adhering to rocks and other algæ.

Dulsin.— A new sweetening product, analogous to saccharin. It is said to be devoid of the injurious properties of the latter, although made from Prussian blue.

Dunlop Cheese. — An excellent article, rich, sweet, mild, white, and buttery, made at Dunlop, in Ayrshire, Scotland. The best are made entirely from new milk. Average composition: Fat, 31·86; casein and albumen, 25·87; water, 38·46; and ash, 3·81. These cheeses are made round in form, and 30 to 60lbs. in weight, very similar in quality to Derbyshire and Gouda, but much larger.

It was originally introduced by one Barbary Gilmour, a farmer's wife, in the parish of Dunlop.

Dunlop cheese has, however, lost ground of late years, and "Cheddar" appears to have been replacing it.

Durians, or Pride of the Malay Isles. — These fruits are the produce of a large and lofty forest tree something like an elm, but with a more smooth and scaly bark, and known scientifically as *Durio Zibethinus*, of the same family as the Kola-nut.

The Durian is round or slightly oval, about the size of a large coker (cocoa) nut, of a green colour, and covered all over with short, stout spines, the bases of which touch each other, and which are consequently hexagonal, while the points are very strong and sharp. It is so completely armed that if the stalk be broken off it is not easy to lift one from the ground. The outer rind is so thick and tough that it never breaks in falling from the tree. Inside it contains five cells, which are satiny-white, and are each filled with an oval mass of cream-coloured pulp, embedded in which are two or three seeds about the size of chestnuts. This pulp is the eatable part, and its consistence and flavour are indescribable. A rich butter-like custard, highly flavoured with almonds, gives the best general idea of it, but with a suspicion of cream cheese, onion sauce, brown sherry, and other incongruities. It is neither acid, sweet, nor juicy; yet it is of a hot humid nature, and although to those unaccustomed to it, it smells very sickly and most like rotten onions, yet by those who have overcome its *civet* odour and its turpentine flavour, it is ranked among the most delicious of fruits, and the natives prefer it to any other.

Durra, Dhurra, or **Dourrah.** — See *Dari* and *Millet Seed.*

Dutch Candy.—See *Sugar Candy.*

Dutch Cheese. — F. *Fromage d'Hollande;* G. *Hollandische Käse;* Port. *Queijo Flamenco;* Sp. *Queso de bola.*

A small, hard, salty class of cheese made in Holland, ordinarily from thrice skimmed milk, which is warmed, and the curd separated by the addition of muriatic acid instead of rennet acid, as in this country. Their toughness and compactness show that the curd has been heated. The salting is effected by steeping them in brine, and during the process of ripening the cheese are damped

with warm whey. In two or three months they are ready for use. In finishing them off castor oil is largely employed. The best known are *Edam* (or *Ball*), *Gouda*, and *Schapekase*, more fully described under their respective names.

Dutch cheeses usually weigh about 4lbs, but sometimes up to 14lbs. each, and are imported loose. About 500 of the ball or Edam shape go to the ton, but 500 of Gouda flats weigh about 2½ tons. They are all good keepers. Alkmaar, in North Holland, is a great centre for these cheese, in fact, the market of that clean and flat little town is the largest in the world for cheese. On Friday, the market day, the whole area is covered with pyramids of what look like orange-coloured cannon balls, but are in reality cheeses. The effect of colour is most brilliant and the scene a busy one. A curious effect is produced by the men who carry the cheeses about, arranging them in pyramids, and others removing them when sold. These porters are always arrayed in white tunics and coloured turbans, the colour of the turbans varying according to the firm of merchants or brokers in whose employ the men are. They work in couples, carrying the cheese on long ladder-like trays, which depend from their shoulders by yokes, so that the weight—sometimes very heavy—is only just raised above the ground. The colour of the trays corresponds to the colour of each set of men. The turbaned porters do not touch the yokes much with their hands, but move along constrained to a peculiar and almost comic gait by the weight of the cheeses on the tray. Both men look in the same direction, one at the front and the other at the tail of the load, and their progress strikes a stranger at first sight as exceedingly droll, but is easily appreciated when understood. The vigorous striking of hands by buyers and sellers is also very amusing. Cheeses from the Alkmaar market go almost all over the world, and are found very cheap and convenient for ship's use.

Dutch cheese are often too salt, and they have at times a most ancient and fish-like smell. This arises from the cows pasturing where the eels have migrated from the canals, which they do at certain seasons in myriads. Their slime gives a taint to the cheese and butter, just as the peaty taste is imparted to Irish butter made on moorland and bogland farms.

Dutch cheese (and Dutch butter) are always much in evidence at Brewer's Quay and in Tooley Street, London.

Dutch Fat.—The commercial name for a low quality of mixed fats, old butter, etc., principally used for frying fish and for making cheap pastry, especially in East London.

Dutch Gin.—See *Hollands*.

Dutch Vegetables.—See *Vegetables in Brine*.

E

Earth Nuts.—A name for nuts which grow in the ground, such as Arachis nuts or American *Pea-nuts* (the negro name in Florida being *Pinders*, and in Virginia and North Carolina, *Goobers*. (See *Ground Nuts, Chufa Nuts*.)

Earth-nut Cake. — The cake, or refuse, which remains after expressing the oil out of earth nuts. If the shells or husks have been removed from the nuts before pressure the cake is called *Decorticated*, but if with the shell on the cake is termed *Undecorticated* Cake.

Earth-nut Meal (also known as *Ground-nut Meal*) is a dark yellow powder made out of the ground shells and seed skins of earth or ground nuts. It has a slightly bitter taste, not free from sand. The name given to this new commercial product is rather misleading, as it denotes the ground kernel and its covering, whereas it is prepared mainly from the shell and outer covering, the nutritive value and digestibility of which is considerably less.

Easteleine.—The registered title of a capital baking powder manufactured by the Easteleine Company at Newbury, Berks. Those who want to sell a really good article should write for a sample, and test it at home, and they will thank the "*Grocer's Manual*" for drawing attention to it.

Easter or **Pasche Eggs.** — These have for many centuries been popular with all Christian sects as symbolical of the Resurrection, and further back still eggs were looked upon as sacred by the Egyptians and emblematic of the renovation of mankind after the deluge.

They appear to have become prominent as an article of diet at Easter chiefly because their use was forbidden among Roman Catholics during Lent; but on the Saturday before Easter, the great quantity of eggs held over for six weeks were blessed and distributed among friends on Easter Sunday. They were dyed yellow, violet, and especially red.

The egg is still the typical emblem of Easter; in some form or other it has been the unquestioned type of the new life from the very dawn of the Christian era. In Russia as early as 1589 eggs coloured red typifying the blood of Christ shed as an atonement for our sins were the most treasured of exchanges at Easter. Every believer went abroad at this season with his pockets well supplied with Easter eggs. When two Russians met for the first time during the Easter holidays, if they had not met on the day itself, the belated Easter compliments were passed, first by shaking hands in silence, then the elder (or the younger, if he outranked the elder), would say: "The Lord is risen," and his companion would reply: "It is true"; then they kissed each other, and ceremoniously drew from their respective pockets the Eastern emblem and exchanged eggs.

The Chinese claim that the world was formed of the two parts of an enormous egg. From the yolk of the egg stepped forth the human being; he waved his hand, and the upper half of his late castle, the egg-shell, went upwards, and became the concave heavens of blue, the lower half fell reversed, making the convex earth, and the white albumen became the seas. The Syrians believed also that the gods from whom they claimed descent were hatched from mysteriously laid eggs. Hence we infer that our present custom of offering the Eastern egg emblem has the heathen legends for its origin.

The custom of presenting them as Easter offerings is more general in Cumberland, Cheshire, and a few other Northern counties than in the South of England.

Many methods have been employed for colouring them. Usually they are boiled very hard in water which has been coloured with red, blue, or violet dyes.

Sometimes they are tied round with different coloured ribbons or pieces of other bright-hued stuffs, and occasionally names and dates are written with grease on the eggs before wrapping them up, so that when boiled the colours dye the eggs, and the writing is left white and legible.

The engraved eggs that are prepared for sale are very puzzling to those who do not know how easily the engraving is done. The writing is done on the shell with wax or tallow, and then the egg is soaked in a weak dilution of some acid, even vinegar will answer the purpose. The shell is partially eaten away by the acid wherever not protected by the wax, and the writing appears in bold relief. This art was discovered in England about two hundred years ago, and the inventor came near being burned for sorcery, as he tried to pass off some of the inscriptions for prophecies.

It is quite wonderful in how many ways Easter eggs may be dyed and ornamented. There is the good old way of dyeing them with terra-cotta brown by adding onion-peel to the water, or giving them a fashionable but unbeautiful magenta tint by means of a spoonful of aniline dye. You can also dye them a lovely ebony-black by putting shoots of young rye into the water in which they are boiled. But they can be made much prettier with very little additional trouble. Draw an outline picture of any flower or animal on white paper, cut it out, gum it on the egg, tie a piece of muslin or other thin material round

the egg in order to keep the picture in its place, and boil the egg for at least five or six minutes. Then take the paper off, and you will find that the coloured egg has a pretty white illustration. Another excellent way is to tie young leaves or simple spring flowers round it, the outlines of which make charming drawings on the eggs.

In some districts a game is played by boys on Easter Monday, consisting of bowling the eggs one against the other, and the egg that breaks first is won by the owner of the egg that strikes it. Even bishops and clergymen used to play at ball with Easter eggs in olden times.

East India Arrowroot, also known as *Curcuma Starch,* is obtained from the tuberous roots of *Curcuma augustifolia,* a plant common in Southern India.

It grows about 3 feet high, and bears yellow flowers.

There are several other species of Curcuma, and it is from these roots that turmeric is also obtained. Most of them possess the same aromatic stimulating properties as the common ginger.

Eating Oils.—See *Edible Oils.*

Eau.— French for *water,* and pronounced like the English letter O.

Formerly the word *eau* (water) was in much wider use than at present. Not only was it applied to every natural liquid, but to almost any liquifyable body. Hence there were *eau de vie* (water of life), *eau-forte* (nitric acid), Lavender-water, Rose-water, and a great number of others. The following are well known, and are elsewhere described under the names of their base or source, such as Brine, Dantzic-water, Orange Flower-water, Lime-water, Florida-water, Toilet Vinegar, and Dentifrices. Others as "Elixirs," Aerated Waters, Mineral Waters, etc.

Eau Creole.—A highly-esteemed cordial made in Martinique, West India, by distilling the flowers of the Mammee apple with spirits of wine.

Eau d'Arquebuse.—A name given in the south-east of France, and especially around Lyons, to a medicated spirit, in the composition of which there are the juices of a great many kinds of plants.

Eau de Barbade.— A celebrated liqueur of delicious aromatic flavour, made in the West Indies from lemon-peel.

Eau de Cologne or **Cologne Water.**—G. *Kölnich Wasser;* It. *Acqua di Colonia;* Sp. *Agua de Colonia.*

An aromatic toilet article or perfume, consisting of alcohol perfumed with essential oils.

It is made from different materials and in several ways. It owes its name to the fact that the first was made at Cologne, on the Rhine, about the middle of the eighteenth century, and was invented by Jean-Antoine Féminis (Fariná), an apothecary of Cologne. It was supposed to possess several therapeutic properties, but it is now fabricated in many other places in France, Germany, England, etc. The original is said to be made from macerations of bergamot, balm, mint, the petals of roses and violets, lavender flowers, wormwood, sage, thyme, orange flowers, nutmegs, mace, cloves, cinnamon, camphor, etc., distilled with spirits.

Every practical perfumer now has his own recipe, and the published formulæ are innumerable. (1) Oil of neroli, 30 minims; oil of petit grain, 10 minims; oil of bergamot, 2 drachms; terpineless lemon oil, 10 minims; oil of thyme, 5 minims; oil of rosemary, 15 minims; alcohol (90 per cent.) to produce one pint. (2) Oil of bitter orange, 3 drachms; oil of neroli, 30 minims; oil of lemon, 60 minims; oil of bergamot, 60 minims; oil of French lavender, 10 minims; alcohol (90 per cent.) to make 20 fluid ounces.

Importers.—F. Newbery & Sons, 27 and 28 Charterhouse Square, London, E.C.

Eau de Javelle.—A strong solution prepared by mixing in suitable propor-

tions potassium carbonate, bleaching powder, and water. It is next filtered, and is chiefly used as an antiseptic and as a bleaching agent for removing stains of ink, wine, etc. Originally produced at the chemical works at Javel, a hamlet in Paris, close to the Champ de Mars Exhibition, but Eau de Javel has during the last twenty years been superseded by the *Extract de Javel*, invented by M. Cotelle, of Ponthierry, S. et M.

Eau de Luce (from *Luce*, the inventor's name).—A compound of mastic, alcohol, oil of lavender, oil of amber, and ammonia-water.

It is used as a stimulant and antispasmodic.

Eau de Melisse des Carmes.—Often called a liqueur, but is merely strong spirit flavoured with balm-mint (*Mélisse citronelle*), hyssop, cinnamon, nutmeg, clove, anise, coriander, angelica, thyme, sage, and marjoram.

It is extensively employed in all French families, and is no doubt a good remedy for nervous maladies, apoplexy, paralysis, indigestion, congestion, and similar sudden attacks of illness. Its origin dates from a long time back. Up to a late period it was in the hands of the Carmelites, but on the dispersion of the religious orders it became the property of a family named Boyer, who have reaped a golden harvest from it. Mdme. Boyer was recently married for the second time to Prince Lubomirski, a well-known Parisian and author of numerous works. Sold in narrow cylindrical bottles.

Eau de Paris.—A substitute for *Eau de Cologne* and similar cosmetics. It is often secretly imbibed as a cordial and stimulant.

Eau de Seltz.—The French name for *Seltzer Water*.

Eau de Vie.—The French name for Brandy, literally signifying *Water of life*.

Eau de Vie de Dantzig.—See *Gold Water*, *Acqua d'Oro*, etc.

Eau de Vie de Piquette.—A spirit distilled from an inferior wine, obtained by washing pressed grapes in water.

Eau de Vie d'Hendaye.—A sweet spiritous cordial, of which there are three varieties—white, which contains the least spirit; yellow, which is the medium; and green, which is the strongest.

Eccles Cakes.—A sort of currant sandwich, very like Banbury cakes, only not made so dry. There is no definite recipe for them, every confectioner using his own way; the great guiding principle, however, being currants, sweetness, and lightness. Many consist of a piece of puff-paste in which a few currants and a little brown sugar, say about four parts currants and three parts raw sugar, are folded, and turned over with closings underneath, rolled out to desired size, then nicked once or twice with a knife on the top, washed with white of egg, and dusted with fine sugar. In Eccles, Manchester, and many adjacent towns, they are baked in a very hot oven, so as to melt and caramel the sugar on the outide of the cake, but it is not a good plan. They look and eat better if baked in a cool oven, and the sugar not discoloured.

Edam, Eidam, or **Ball Cheese.**—(See also *Dutch Cheese*.)—A popular kind of hard and salty Dutch cheese, of globular form, made in moulds, from milk coagulated with muriatic acid instead of the usual rennet.

The northern part of Holland is the seat of the industry, and the consequent cleanliness of the relish is, therefore, doubly assured. In making it the fresh cows' milk is carefully strained and the acid added. As soon as the milk curdles the whey is drawn off, and the curd, thoroughly kneaded, is pressed into moulds. This process is repeated until the whey has all been extracted and the curd is comparatively dry. It is then wrapped in a linen cloth and kept for ten or twelve days until quite solid. Then the cloth is removed and the cheese put into salt lye. Afterwards a little more dry salt is sprinkled on the cheese, until the maker thinks it is salt enough to insure its keeping. It is next put into a vessel, and, after being washed with whey, is scraped to

remove the white crust. It is next carried into a cool room and laid on shelves, where it is frequently turned. The ripening process lasts from two to three months, the round balls growing the fine yellow or reddish colour peculiar to Edam cheese.

It is below the standard as regards fat, and contains as much as 4 or 5 per cent. of salt. The outside is usually coloured a deep red with a preparation of madder or annatto, and the cheeses intended to be exported to this country are rendered still more brilliant by dyeing the rind with a vegetable dye. They keep best in tin-foil, as this prevents to a great extent drying up; but when in foil it is well to grease them. Some people oil them and wrap in brown paper for keeping a long time.

(Two other popular sorts of cheese are made in Holland, viz., *Gouda* and *Schapekase*, which see.)

Eddoes, Eddas, or Edders. — These are West Indian names for the tubers of various species of *Colocasia*, or *Arum esculentum*.

In some places they are known as *Cocos*. They are roasted and eaten same as potatoes. Sometimes they are stewed for a couple of hours in their skins, and then peeled for the table.

The leaves of the plant are also boiled and used as spinach, and the corns are used for soups.

Imported mostly in barrels. Price about 20/- per cwt.

Edible Bird-Nests.—Ch. *Yin wo*; F. *Nids d'hirondelles*; G. *Indianische Vogelnester*; Hin. *Ahabel*; It. *Nidi di Tuchino*; Jav. *Sosuh*; Mal. *Sarang-burang*; Sp. *Nidos de la China*.

These edible bird-nests—or rather portions of nests—are those of a small dark-coloured species of swallow, which inhabit certain rocky coasts in the Eastern World. The birds are known as *Collocalia esculenta*, have a greenish hue on the back, and a bluish one on the breast, and have no white marks. Various types of the species are found in Sumatra, Java, Borneo, Celebes, Andaman, and other islands in the East Indian Archipelago.

Large quantities of the nests are received at the British Island of Labuan, at the North of Borneo, from Sandakan Bay, and Kina Batangan River, on the east coast, where they are found on the walls of caverns in limestone and sandstone hills all along the coast.

Naturalists cannot quite agree as to what the mucilaginous substance really is—whether a kind of seaweed, like Agar-agar, or a secretion which the birds themselves discharge from their salivary glands. The nests are very much like swallows' nests, and the edible portion consists of the glutinous material forming the outer or lower part, which supports the nest proper and attaches it to the water-worn limestone and sandstone rocks and caves.

The nests seem to be used as food by the Chinese only, but they regard them as very choice delicacies, also with valuable curative properties, and will pay extravagant prices for them.

Large numbers are exported from Siam to China. The Governor of Chaiva up to the end of 1896 farmed the nests at Champawn of the Siamese Government at a rent of £2,240 a year; guards or watchers cost him another £1,000 a year.

These birds are known as Swifts, or Peale's Swiftlets (*Collocalia spondiopygia*), and build their shallow cup-like nests against the rocks and in the caves. The silvery appearance of each nest, and the absence of all but the finest threads and attachments, make it look like beautiful white gelatine.

In Singapore, which is the chief mart for this commodity, the newest and whitest nests, resembling isinglass in colour, fetch as much as 80/- to 120/- per lb., while those obtained after the young are fledged are darker in colour, and only bring 40/- to 60/- per lb. The blackest or dirtiest sell at still less. It requires about fifty nests to yield a pound; but they are commonly sold by the "catty"—say, *white* at 45/-, dark or red 20/-, and black at 4/2 per catty. The gathering and drying cost very little, hence the price is nearly all profit to the respective potentates of the islands where the birds congregate, and

where they are jealously guarded as valuable State property.

The nests are readily soluble in alkaline solutions, but scarcely so in hot water, and still less in cold. The Chinese carefully wash them several times, picking out any feathers, bits of sticks, dirt, and other impurities, and then stew them into a gelatinous pulp, after which they are added to soups, etc., to which they impart a peculiar rich, spicy, and aromatic flavour. These dainties are usually served at the close of a repast, and at the rate of about a nest and a half to each Celestial guest, but they do not appear to have any more real nutritive or medicinal qualities than ordinary isinglass.

Edible Earths.—The inhabitants of many countries, especially during famine and times of scarcity, use certain kinds of earth as food. In Spain a kind of earth known as *bucaro* is eaten; the Russian peasant partakes of his *rock-flour;* the Thuringian of his *rock butter;* the Swede of his *bergmehl,* or mountain-meal; the native of Java of an earth known as *teneampa;* the Hindoo of the so-called *Patna-earth;* the Persian of a species of soil known as *Gheli giveh,* and a peculiar white clay found near Kum, in that country; the poorer classes in the Neograd district of Hungary eat an earth chiefly composed of lime and carbonic acid; another kind of air-dried powder, consisting mainly of alumina, is mixed with flour by the Laplanders and made into bread, and a clay, mostly silica and alumina, found in Mackenzie County, South Island, New Zealand, is said to be largely eaten by sheep.

Edible Oils. — F. *Huiles comestibles.*

The "Comestible," "eating," or alimental and cooking oils comprise Olive oil, Refined Cotton-seed oil, Beech-nut oil, Dogwood oil, Linden-seed oil, Kapok oil, Poppy oil, Safflower oil, Sesame oil, Sunflower-seed oil, Ground-nut or Arachis oil, Brazil-nut oil, etc., and these are described fully under their respective names.

They should not only be free from the least taint in taste or smell, but possessed of a delicate, appetising flavour. They are apt to turn rancid if kept too long, but may be considerably rectified by filtering through charcoal which has been soaked with a solution of soda. In case of a large quantity, it is best to filter it through a cask which has the bottom perforated with a number of small holes. The inside of this cask should then be lined with flannel, and over this a layer of impregnated charcoal six or eight inches thick, to which another layer of animal charcoal may be added, if the oil has to be decolourised.

Many refiners now mix two or three vegetable oils together, so as to produce a special blend of their own, and then register it under some fancy name.

Eels or Snigs. — These fish (Anguilla vulgaris), chiefly found in warm fresh water rivers, meres, lakes, and ponds, are considered very nutritious, and their consumption in great cities is very large. Nearly 1,000 tons come from Holland yearly. The Dutch shippers keep them alive in tanks, and send them to Billingsgate in cargoes as required. There are three or four species of eels, viz., the sharp-nosed, which is the kind usually seen; the broad-nosed, or glut-eel, and the yellow snig-eel. The Conger-eel is a larger marine species, but coarser flavoured. Young eels are often called "grigs." Eels cannot bear much cold, and, although usually buried in mud or sand, often perish in severe winter weather.

Effervescent Citrate. — A name applied to imitation citrate of magnesia to evade the *Food and Drug Act.*

Eggs.—Da. *Eg;* F. *Œufs;* L. *Ova;* G. *Eier;* Port. *Ovos;* Rus. *Irka;* Sp. *Huevos;* W. *Wyau.*

The world's egg trade is gradually acquiring increased importance. The value of eggs and poultry imported into England from abroad increases yearly, altogether amounting to about half the cost of our Poor-law administration. They arrive from France, Germany, Italy, Austria, Denmark, Canada, Ireland, Belgium, and Russia. Canada now

sends us four times more than the United States send; while the English farmer only looks on and grumbles, or, with his landlord, asks for *duty* to be imposed, or for each egg to be marked, so as to hamper the trade.

The yearly consumption of eggs per inhabitant in England has been calculated approximately as follows:—1811 to '30, 40; 1831 to '50, 48; 1851 to '70, 60; 1871 to '80, 65; 1881 to '88, 70; 1889 to '93, 80; and 1895 to 1900, 85.

France is particularly celebrated for its egg products, and the hatching and rearing of poultry is there a lucrative industry.

The chief ports for shipping are St. Malo, Rennes, Honfleur, and Havre. The dealers collect the eggs daily with systematic regularity from the farmers, and take special care to ship them *fresh*—hence the preference and high prices these obtain. They are often consumed in England within three days of being laid, whereas English and Irish eggs are carried to the markets only once a week or fortnight, and are liable to be two, three, or four weeks old before they are actually eaten.

The London Egg Market, Ltd., the chief market in England for eggs, is held at Nos. 8 and 9 The Hop Exchange, Southwark Street, London, Monday forenoon being the busiest time, when immense numbers change hands. Terms, 7 days and dis. 2d. in the £1. For broken or bad eggs half a hundred (60) eggs on every case, 30 on half a case.

As eggs contain all the essentials for the nutrition of a young animal, they form, like milk, a highly nutritious diet for adult organisms. As is generally well known, they contain albumen, fat, lecithin, and phosphates.

The average weight of the newly-laid egg is about 2½ ozs., and its specific gravity from 1·080 to 1·090. The "white" usually weighs 1½ ozs., the yolk almost ¾ oz., and the shell and skin about ¼ oz. The real value of an egg, however, depends not only upon its weight and freshness, but also on the breed of the fowl. The freshest eggs are the heaviest, and placed in water sink to the bottom, while stale eggs float on the top. The age of eggs may thus be closely estimated by their density:—Dissolve a given weight of salt in ten times its weight of water, or, say, 1lb. of salt in a gallon of water. A newly-laid egg will sink to the bottom at once, a one-day-old egg will not quite go to the bottom, an egg three days old will be suspended in the liquid, and older ones (as well as bad and worthless ones) will float at the top, or project above the water more and more in proportion as they are older. It is also a sure sign that an egg is stale or rotten if it shakes or rattles when moved, the yolk being evidently loose.

Spotted eggs.—This is usually caused by damp, and such eggs are considered bad, even if only with a single small spot.

"Candling" eggs is a popular mode of examination to which eggs are subjected by the dealers. Newly-laid eggs appear clear or semi-transparent, with a pinkish tinge, when placed between the eye and a strong light, and have a small but perceptible division of the skin from the shell, at the large end of the egg, which is filled with air. A simple lamp for "candling" eggs has recently been patented, which enables a dealer to make the tests in any subdued light. An ordinary kerosene-burning lamp, backed by a strong reflector, furnishes the rays. The front of the lamp is shielded by an upright of black japanned tin, supplied with a broad, stubby spout, into the end of which the egg is laid. The light of the lamp is concentrated through that spout, and the egg becomes almost transparent. The larger end of a newly-laid egg also feels cold when placed against the tongue, but they are commonly examined by the light of a candle or lamp. *Fresh* eggs are thus easily known by their fulness and transparency when held up to the light.

In stale eggs the yolk is darker in colour, the air cell is large, and the germinal spot is clearly visible. A still further stage is noted when a large dark cloud is observed surrounding a large air-cell and the germinal spot. By keeping eggs they always become cloudy, and thus when decidedly stale the distinct dark cloud-like appearance is discernible opposite some portion of the shell. The

first stage of decay is evidenced when the yolk has penetrated the white and the air space between the shell and the skin and fastened itself to the shell, showing the dark spot that does not move when the egg is turned. There is a constant evaporation going on in every egg from the time it is laid, so that aged eggs will generally rattle when shaken. In a fresh egg about 74 per cent. is water. With eggs a few days old, evaporation is scarcely discernible by "candling"; in the first week it is hardly noticeable, but more marked in the second, and of considerable importance in the third. This loss (evaporation) is four times greater in hot weather than in cold. Twenty-seven eggs will, at the end of six months, weigh less than twenty-two newly-laid ones of same size. Eggs weighing 10 to the pound lose double that of eggs weighing 8 to the pound, and with very small and long eggs the loss in weight assumes a still greater disproportion. There are other devices for examining eggs—

(1) A little instrument called an Egg tester is sold. It consists of a small square box, with a hole at the top to receive the egg, and another at one side to look into. By an arrangement of mirrors within the state of the egg is seen when a strong light is thrown upon it, so as to be transmitted through. If the egg be fresh, the image seen in the mirror is almost transparent, whilst, if stale, it is more or less dark.

(2) Place the egg in a hole in a piece of cardboard, holding it between the eye and the light of a candle or gas burner. A new egg will have no void, but after two days it will shrink away from the larger extremity, and the egg gradually becomes cloudy in the centre.

(3) Place the egg against the closed eye-lid, and if the end of the egg is void it will feel warm, whereas if the egg be new laid it continues cold.

(4) A way to prove bad eggs is to put them in a pail of water. If bad they will stand on their small ends (unless they have been shaken very much). If they lie flat on their side they are good enough to eat.

Farmyard fowls average 60 or 70 eggs in the year, but certain Cochin China breeds are said to lay 200 to 300. Large eggs generally have thickest shells.

The eggs of ducks, geese, and other aquatic fowls have the surface polished and lustrous. This seems a provision of nature to protect the contents from the effects of cold and damp. Hens lay more eggs during their second and third year than in their first or fourth year, and after the fifth they generally cease laying.

Weights and numbers of Eggs laid by various fowls:—			
Light Brahmas and Partridge Cochins	7 to the lb.	80 to 100 a year.	
Dark Brahmas	8 "	70 "	
Black, White, and Buff Cochins	8 "	about 100 "	
Plymouth Rocks	8 "	100 "	
Houdans	8 "	150 "	
		(If non-sitters.)	
La Flèche	7 "	about 130 a year.	
		(If non-sitters.)	
Black Spanish	7 "	about 150 a year.	
Dominiques	9 "	130 "	
Game Fowl	9 "	130 "	
Crèvecœurs	7 "	150 "	
Minorcas	7 "	180 to 200 "	
Leghorns	9 "	150 to 200 "	
Hamburgs	9 "	170 "	
Polish	9 "	150 "	
Bantams	16 "	160 "	
Turkeys	5 "	30 to 60 "	
Ducks, vary	5 to 6 "	14 to 28 "	
Geese	4 "	20 "	
Guinea Fowls	11 "	60 "	

Goose Eggs.—Geese begin to lay about Candlemas, and lay 9 to 11 eggs, but, if well fed and the eggs are removed as laid, 35 to 40 may often be obtained; the eggs are inferior in quality.

Duck Eggs are about one quarter more nutritive than hens' eggs, are of a greenish colour or dark white colour, and the yolk is larger and of a deeper colour than the eggs of the hen. The white also, by cooking, assumes a transparent or isinglass consistency. The keep of ducks is also cheaper. *Pea-fowl* or *Guinea-hen Eggs* have a thick and hard shell, flesh coloured, and the yolk is proportionately much larger than the white.

Turkey Eggs. — The turkey-hen ordinarily lays 12 to 20 eggs, which are rather smaller than those of the goose, and which are white mixed with reddish or yellow freckles. They are considered

very good in pastry, and, mixed with fowls' eggs, they improve omelettes.

(For *Plover Eggs* and *Turtle Eggs*, see these headings.)

The shells of all eggs are studded with small holes, which are the means of absorption and exhalation by which the young respires. These orifices are most clearly visible in ostrich eggs, but are very minute in these of small birds. As already observed, soon as an egg is laid it begins to evaporate and loses both weight and volume, especially during warm weather; consequently perfect eggs are not so readily procured in summer as in winter. If by any means this evaporative process can be stopped the egg will remain sound a very long time.

The shell of an egg is lined with a very thin but tough membrane, which, dividing very near the obtuse end, forms a small bag, which is filled with air. In newly-laid eggs this follicle appears very small, but it becomes larger as the egg is kept. In breaking an egg this membrane is removed with the shell, to which it adheres, and, therefore, is commonly regarded as part of it, which it is not. The interior consists of a viscous colourless liquid, called albumen, or the *white*, and a yellow globular mass, called the vitellus, or *yolk*. Few persons who break eggs ever notice that the "white" consists of two parts, each of which is enveloped in two distinct membranes. The outer bag of albumen, next the shell, is quite a thin watery body, while the next, which invests the yolk, is heavy and thick; but each has its use during the process of incubation. The yolk is made up of water and albumen, oil, sulphur, phosphorus, and a number of other substances. The sulphur acts chemically on silver spoons, turning them black and forming a sulphide of silver that can only be removed with the surface of the spoon itself.

The flavour of eggs is much influenced by the nature of the package, for they imbibe foreign odours with the greatest readiness. Eggs brought in the same ship as oranges take the scent and flavour of the fruit. If the cases are made of green wood, the flavour of the eggs will be injured.

Eggs keep best in a cold temperature, say 36° F. (almost freezing point), and they should be turned frequently if they are to keep good. If this be not convenient, they should be stored where there is a through draught, or over a grating, or they will acquire a musty "straw" taste.

We have seen lots of eggs which have evidently been dirty when collected, which the packers have ignorantly washed as clean as possible with the hope of increasing their value. For the most part they soon go bad and often rotten. When an egg is soaked in water sufficiently to enable one to remove the dirt from it, the gelatinous substance which ordinarily fills the pores, in the lime of which the shell is mostly composed, becomes dissolved, thus subjecting the inside of the egg to the destructive effects of the air.

A better price is usually obtained for the buff or brown-tinted eggs produced by the Leghorn fowl than for white-shelled, because they are fancied to be richer, and they look nicer on the breakfast table.

Comparatively few persons know how to boil an egg properly. They will tell you to drop it in boiling water and let it remain three minutes, and to be sure that the water is boiling; but an egg so prepared is very indigestible, and hardly fit for a strong healthy person to eat, while it would be very injurious for a delicate person or invalid. The moment it is placed in boiling water the white hardens and toughens. To boil an egg properly it should be put in cold water, placed over a *slow* fire, and the moment the water begins to boil the egg is done. The white will be found delicate as jelly and as easily digested, also nutritious, as it should be.

Fresh Eggs can be easily flavoured to suit the fancy. They absorb any odour with which they are placed in contact; and the storing of them in baskets filled with roses and violets results in a novel and pleasant experience. As already observed, fresh eggs will keep for a much longer time if turned or the position be altered from time to time, so as to prevent the yolk settling and becoming attached to one side of the egg. Some dealers, therefore, keep them in slings

so as to be more easily turned. Eggs should never be exposed to the glaring heat of the sun, nor should they be placed near cheese, fish, or other article of food from which any odour rises; oil, lard, butter, or other greasy matter also spoils their appearance. They are extremely active in absorbing power, and in a very short time they are contaminated. Eggs may be considered "fresh" during the first fourteen days after being laid.

Irish Eggs have long enjoyed a high reputation in England, and would, doubtless, maintain it if better attention were paid to cleaning, sizing, and honest packing. They would also sell much better if graded according to weight and size. They are too often either dirty or carelessly and unsafely packed in coarse, unsightly, foul-smelling cases. They should never be packed in fresh straw, however clean, but in sweet straw that has been well dried and seasoned in warehouse or stove, also in new and more attractive cases. Few buyers are indifferent to such details. But the greatest danger to the Irish egg trade is the fact that large numbers of Foreign eggs arrive at Belfast and other ports from the Baltic, and are afterwards mixed and packed in Irish cases for England. What else do they want with Foreign eggs in Ireland? Irish cases are also often refilled in England with Foreign eggs, and then resold as "Irish."

Market Weights of Irish Eggs, per great hundred (120): — Specials, 18/20lbs.; Extras (brown), 17½/18lbs.; Selected, 17lbs.; Medium, 14½/15lbs.; Chats, 12/13lbs. per 120.

Foreign Eggs are usually sold in cases of 1,440, half-cases of 720, or quarter-cases of 360, with a breakage allowance of 60 on each case; but this custom seems to prevail in the South of England only, and in the North no such allowance is made.

Imports in great hundreds (120).	1899	1898	1897

This shows that in 1899 the U. K. imported nearly 2,000 millions of eggs, at a cost of nearly 6 millions of money. Most of the Russian are really the produce of Austria-Hungary and most of the Belgium are Italian and Austrian, while many from France are Austrian also.

Danish Eggs are frequently sold wholesale by weight. "The Danish Andels Egg Export," a national association of some 18,000 farmers, was formed in 1895, and has established depôts or packing-houses all over that country. An agreement is entered into by all the members to clear the nests daily, keep the eggs spotlessly clean, and deliver weekly to the depôt or packing-house. Any infringement of the conditions involves penalties. This system ensures perfectly fresh and clean eggs, so that the association in exporting is enabled to guarantee perfectly new-laid eggs. Private exporting merchants are, of course, intensely opposed to the plan, but it has succeeded by leaps and bounds.

Russian Eggs.—There are in St. Petersburg, Odessa, and the principal towns in the south-west organised native and foreign companies, which have a large number of agents travelling through the towns, villages, and farms, who buy up enormous quantities of fresh eggs. Russia is, in fact, one of the largest egg-producing countries in the world. The exports to Western Europe in 1897 were close on 30,000 tons, equal to about 430 million eggs!

The principal markets are Kozlow, Riga, Orel, Warsaw, and Libau.

The eggs are carefully packed with kiln-dried straw or shavings in cases, which are immediately sent to the central agency for transhipment abroad, especially during May, June, and September, but July and August are too hot. Eggs can be delivered in England within twenty-one days from the farthest districts of Russia, and from many districts within fourteen days. Each Russian case contains 1,500 eggs, and thousands of cases are dispatched. Germany takes most and England comes next; but from the sea passage

and damp climate of England they will not keep over twenty-one days after arrival, and are frequently very dark in colour, inferior, and sometimes almost useless. Russian eggs weigh about 105lbs. per 1,000.

Canadian Eggs promise well, and fetch better prices than Irish. They weigh 15 to 17lbs. per great hundred (120), while the best Continental weigh 13 to 15lbs. only.

In *Belgium* they are sold wholesale by weight; a case of 1,440 (10 gross) averages about 55 kilos nett. British traders. also, are beginning to require guaranteed weights per 120, so as to compare with Continental prices.

Austrian Eggs weigh about 110lbs. per 1,000 and *Italian* about 118.

Eggs should never be packed in cases made of green timber, but from boards which have been well seasoned. Wood wool is considered far safer than straw for packing eggs, as it has no fusty smell; but, of course, kiln-dried straw is much better than straw, containing all its natural moisture. As already stated, Irish eggs are often spoilt in flavour by persistent carelessness in this respect. Damp straw or hay soon leads to mustiness, decay, and putrefaction. The shell of the egg being porous, the contents are easily affected by any strong odours. Cardboard cells and soft spruce shavings are probably best of all.

It has long been felt that eggs should have a more definite classification than is conveyed by the ordinary market terms "Extras," "Selected," Re-selected," "Ordinaries," etc., these words being somewhat vague, and often inaccurately employed. The terms "New laid" and "Fresh" are also quite unreliable, the former often being four or five weeks old.

Eggs are more plentiful in summer than in winter, and although fowls may to some extent be induced to keep on laying longer by feeding them on morsels of uncooked beef and fat, and by mixing a little cayenne with their food, yet eggs are every winter 35 to 55 per cent. dearer than in summer.

Preserved or *Pickled Eggs.*—Many careful experiments have been made during the last ten years. It has recently become very common, when eggs are cheap and plentiful, to import foreign, and even Irish, eggs, and store the cases in cold chambers, until newly-laid eggs become scarce and dear. Owing to the development of the system of refrigeration on shipboard, Australian eggs are now put on our markets in such condition that they pass readily for newly-laid eggs; but this management is not generally practicable, nor is it advisable.

The best method of preserving eggs, and one that may be depended upon, is to get the eggs fresh as possible—or at most not more than 12 or 14 days old. Tap them gently against each other to make sure they are all sound, or a broken one may afterwards go bad and injure the flavour of the lot. Pack the eggs carefully in a clean jar, keg, or other water-tight vessel, arranging each egg small end down. When the vessel is nearly full fix a few clean wood splints over the eggs so as to keep them from floating. Then pour in a *solution of waterglass* until the eggs are well covered, tie a piece of paper over to keep dust out, and stow away in a cool pantry or cellar. The solution is only a mixture of crude waterglass (price 10s. per cwt.) and water—say, 1lb. of unrefined waterglass, dissolved in 1 gallon of clean water which has been boiled. It must not be poured on the eggs until it is cold. The cost is altogether trifling—about a halfpenny per score of eggs—and every egg should keep good six or nine months at least, and their "whites" may be afterwards beaten to a froth; but, being thus coated with waterglass, the eggs are apt to crack or burst in boiling, thus letting in water, unless before cooking, the shell be pierced with a needle.

2. Another way is to rub each egg over lightly with waterglass (unmixed with water), covering every part of the egg, so as to render it air-tight. Then pack the eggs in a box or jar, and cover it over with paper to keep them clean.

3. Another reliable method is to rub the eggs over with a rag or sponge smeared with vaseline or petroleum jelly.

4. The pickling of eggs in lime is an old Dutch process, first introduced into England in 1788, and still much in vogue. Mix in a wood or brick vat, or cask, say 20 gallons of water, 4 gallons of fine slacked lime, and 1 gallon of salt. Add a little fresh lime-water once a week, or else hang a bag of fresh lime now and then in the water. These lime plans are much the same. Take care the lime and eggs do not cake at the bottom. The water must have as much lime as it is capable of holding, but the lime must not be thrown into the eggs or it will be sure to cake at the bottom. The better plan is to make the lime-water first, and see that there is no sediment. When wanted for use the lime coating is easily removed by pumping water on the eggs.

Numerous other methods of preserving eggs are in use. The idea of all of them is to keep air out of the eggs, as by such absence of oxygen, decay can be arrested for a considerable length of time, especially if the eggs are perfectly fresh at the start and are kept in a cool, dark place.

When taken out of pickle they are apt to deteriorate, like fresh eggs, and are undoubtedly fittest for cooking purposes.

On breaking a pickled egg it will be noticed the white of the egg has become quite thin and watery. They should in all cases be preserved while fresh.

Chinese Method.—Immense numbers are preserved in Chinkiang, especially duck eggs, ducks being very prolific in that region, and it is no unusual thing for a farmer to keep 4,000 or 5,000 ducks under his care. The process is very curious. A lye of bean-stalk and lime is made by burning these to powder. This is boiled in water, black tea leaves and salt in certain proportions being added. The boiling is continued until all the water has evaporated, and the residue becomes caked and hard. This is pounded and the fresh eggs are placed therein, one by one, with a little rice husk. These remain in the preparation 100 days, when they are ready for use, or will keep good 10 or 20 years. The egg treated in this way looks like a ball of dry clay. For transport they are usually packed in sacks with rice husks. In China, however, these eggs rise in value according to age. After 25 years they are considered exquisite to the taste, having undergone a kind of transformation, the result of which is that the yellows have become a kind of dark brown, and the whites also brown, resembling meat jelly. Such eggs are usually reserved for ceremonials and great occasions, but not having tasted them we cannot recommend them!

Many thousands of cases of preserved eggs have been coming to this country every year. Belgium perhaps sends the most, but as that country cannot really produce enough for her own consumption, eggs are extensively imported there from Italy, Austria, Russia, etc., and are consequently somewhat deteriorated by transport first to Belgium and thence to England.

But it seems likely that in future imported eggs may be kept in cold storage for several months till the market prices suit the merchant. Whether such eggs will be allowed to be retailed as "fresh" remains to be seen. To sell pickled or preserved eggs as fresh is a fraud punishable by fine or imprisonment. Doctors often prescribe their convalescents new-laid eggs, as these are more easily digested, but pickled eggs might cause serious results.

Special Firms.—Henry Bird, 15 Farringdon Road, London E.C.; John Hayes, egg exporter, Tralee, Ireland; M. & W. Jones, exporters, Villa Nova de Gaya, Portugal; W. A. McKnight (Canadian), 24 and 26 Mathew Street, Liverpool; J. J. Metcalf & Co., 45 Whitechapel, and 21, 23, and 25, Sir Thomas Street, Liverpool; George Wall & Co., Ltd., Liverpool and Manchester (see advt. page 10); Thos. Wilson & Co., Hood Street, Liverpool.

Egg Colouring.—This usually consists of sugar coloured by the addition of aniline dyes. Powdered turmeric is also used.

Egg Julep.—The majority of egg juleps are nothing but alcoholic solutions of soft soap suitably perfumed. In some recipes, however, the white of egg is used, as this has a very decided fixing property on the hair. Example: Soft soap 1 oz., whites of two eggs, essence of opoponax 4 ozs., glycerine 4 ozs., and rose water to make up 4 ozs.

Dissolve the soap in 10 ozs. of the rose water, gradually rub down the white of egg with another 10 ozs. and the glycerine. Mix, add the perfume, and then enough rose water to make up 2 pints.

Egg Plant.— F. *Aubergines;* G. *Melanzäpfel.* (See also *Vegetable Marrows.*)

Egg-plant, or *Solanum melongena*, is a member of the *Nightshade* family, and known by several names. Throughout the East it is a favourite food, and called *Brinjal* or *Aubergine*, but this latter is hardly identical, though closely allied.

In the United States, where it is also popular, it is called *Jew's-apple, mad-apple*, etc. It thrives in most of the warmer climates, and is often cultivated in English hot-houses, but suffers greatly from the attacks of the potato bug. It is an egg-shaped fruit, akin to the tomato, but varies in colour from a yellowish-white to violet or dark purple, and the plants, set out about 3½ feet apart in rich ground, grow about 2 feet high. The fruit of the egg plant is highly esteemed either sliced and fried, or in soups. It is, however, more popular in France, Italy, and America than in England.

How cooked in New Orleans.—Slice the plant into pieces about quarter of an inch thick, sprinkle with salt and pepper (perhaps cayenne is best), and then with flour cook it like a pancake in a frying-pan, with a little butter or olive oil, but be sure and fry brown in the fat first a few thin slices of onions, and when brown remove them from the hot oil. Time, ten minutes.

Egg Powders.—Generally composed of rice flour, bicarbonate of soda, and a little tartaric acid, coloured

slightly with either turmeric, chrome yellow, or an anfline dye; say, half a drachm of finely-powdered turmeric to each pound of the mixture.

Example:—Mix 2lbs. carb. soda, 2lbs. cream tartar, ½lb. tart. acid, ¼lb. ground turmeric. Some are merely tinted corn-flour mixtures—say, 32 parts corn-flour, 1 turmeric, 4 sugar, and 2 of powdered gum tragacanth, flavoured with vanilla or lemon, and well mixed.

Others are made up chiefly of dirty or discoloured rice concealed in colouring and flavouring matter.

The public in buying egg powders often think they are getting some kind of concentrated essence of egg, powdered egg, or some ingredient similar to egg itself, and we have heard of them being given to children under the impression that they were very strengthening. It is obviously incorrect and improper to apply the name to eggless powders, for they usually differ only in colour from baking-powders. One concoction, widely advertised, consists of, say, 36 parts corn-flour, 1 turmeric, 4 sugar, and 2 of powdered gum tragacanth, the whole being mixed and flavoured with a little vanilla. Some sorts contain large proportions of alum, as much as 40 per cent. having recently been found in a noted make.

Gardner's patent "Rapid" sifter and mixer freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester. For a very good powder apply to The Easteleine Co., Newbury, Berks.

Eggs, White of (also known as *Desiccated Egg*).—White of egg (*Albumen ovi*) is nearly pure albumen dissolved in water. The substance appears in a beautiful crystalline form, very like fine gum arabic, and will keep good for many months. When required for use it is dissolved in tepid water for a couple of hours, and the liquid can then be beaten to a good firm snow, just like fresh egg.

It is used as a glaze or varnish for photographs, and for clarifying various liquids, wines, syrups, jellies, etc., also for making meringues, nougats, icing, pastry, etc. Some is used in calico printing and as an antidote for certain poisonous substances.

Large quantities are exported in tins from Russia and Germany. Commercial qualities are classified as (1) free from acids and odourless, (2) fine, (3) ordinary, and (4) powdered.

This preserved white of egg is only about half the price of fresh eggs. A substitute often used by confectioners is made by melting 2 ozs. French medal glue in a quart of boiling water.

In 1897 a German firm started an albumen factory at Wuhu, in China, where ducks' eggs only cost, say, 3/- per 1,000, and girls for separating the yolks from the whites can be hired in any number for about 1/3d per week. Other factories have been since established, and there are now six in China—five German and one French—but the price of eggs has risen to 16s. per 1,000. A thousand eggs yield 13 to 15lbs. of albumen, which is sold at about 3/- per lb., and the yolks are employed in the tanning industry.

The yolk of the eggs after separation from the white is passed through two sieves—one coarse and one fine—and it is then run off into vessels holding about 20lbs. each, in the form of a yellow, even running liquid, of the consistency of rich cream. It is then poured into vats holding about 100lbs. and a 10 per cent. solution of salt, borax, and an unrevealed chemical then added for the purpose of preservation. The mixture is stirred until it assumes the consistency of thick molasses and of a dark orange colour, and is then poured, or rather forced, through a funnel into a cask holding about 500lbs. This is used in the preparation and dressing of superior leather goods, and is in great demand in England, France, and Germany. (See also *Liquid Eggs*.)

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Egg Yolk.—The yolk of eggs is sold in casks of about 4 cwts. each, as well as in tins. There are three commercial classes, (1) fresh preserved, (2) 12½ per cent. salted, and (3) dry powdered. It

is mostly imported from Russia and Germany.

The Armour Packing Co. has also embarked in the business of separating the whites and yolks of eggs, canning them separately, freezing them, and unloading them on the market, and has succeeded in creating a great demand for their new product. As they are canned at the present time, some 30 dozen eggs are put up in a two-gallon can, which is exactly the number that a case holds. When a baker uses 30 or 40 dozen eggs in a day, it takes time to break the eggs and separate them. The new plan saves time. Egg yolks are also employed in glove making and the preparation of calf-kid leather.

Egg yolk may be preserved for some time without losing its clearness or colour and without acquiring any smell, by adding to it 5 per cent. of neutral sulphate of soda, either in a powder or concentrated solution.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Egyptian Coffees comprise the coffees of the Upper Nile region, that grown around Berber and the Soudan, also including small African varieties, very little being grown in Egypt itself. Being the product of different districts, they vary in size and quality, ranging from small to medium, of pale-green colour, flat or regular shaped, but yield superior liquors.

Many of the smaller berries are put up in Mocha grass-mat bales at Alexandria, and sold under the name of "Short-berry Mocha," and are known to the initiated as "Alexandrian or Egyptian Mochas."

Elatchee. — An Eastern name for *Cardamoms*, which see.

Elder-berry Wine. — F. *Vin de Baies de Sureau*; G. *Hollanderbieren wein*; It. *Vino di grani di sambuco*; Sp. *Vino de granos de sahuco*.

A grateful wine made from the bright crimson juice of the small black berries or fruit of the elder shrub, *Sambucus nigra* (not the *alder* tree), which is common all over Britain, and is one of the few large shrubs that grow well in large towns.

The young leaf-buds are exceedingly purgative; cattle will not eat them, and even mice, rats, moles, etc., will avoid their proximity. The dried white flowers are often used for flavouring wines and confectionery, and the ripe berries are said to be largely used in England for the adulteration, or fabrication, of port wine.

Elder berries have an acidulous and sweetish, but somewhat unpleasant, taste. The inspissated juice is often employed as an aperient and a diuretic.

Elder wine is usually flavoured strongly with cloves and other spices, and often drunk hot, or mulled, with toast. Considered to be laxative, and good for coughs, colds, sore throats, etc., also for gout, rheumatism, and syphilitic eruptions.

How made.—Pour 3 gallons boiling water on 20lbs. ripe elder berries, free from stalks. Let stand for 24 hours, then break up the fruit, strain, press, and filter through a bag.

To every gallon of the juice add 3lbs. white sugar, ½ oz. freshly crushed ginger, 1 drachm cloves, 1lb. stoned Valencia raisins (not Sultanas). Boil the mixture for an hour, skimming thoroughly during the process. Let it cool at 98° F., strain into a clean cask, add 2 ozs. yeast for every 9 gallons of the liquor; let it ferment for 14 days, then add 5 fluid ozs. brandy for every gallon of liquor. Finally, bung up tight, and let it alone for 6 months before bottling off.

Eleme Figs.—(See also *Figs.*) — A choice quality of dried Smyrna figs, "*Elémé*" being a Turkish word for "hand-picked."

The bulk of the fruit is grown on the lowlands, and 50,000 or 60,000 camel-loads are carried into the port of Smyrna every year from the surrounding country; but a great portion is, of course, only shipped as "naturals." Elémé figs are the kind commonly used for dessert and usually packed in small square boxes, with a few bay leaves interspersed among the fruit to protect it from the

ravages of a destructive grub with which it is liable to be infested.

Eleme Raisins.—These are imported from Turkey, and generally shipped from Smyrna. They are a long raisin, "hand-picked" from the stem, light brown in colour, mostly used for ship stores, and of but little interest in England. The new fruit reaches here about October.

Elephant Coffee, or *Victoria Coffee.*—These are cheap compounds of roasted sugar-beet, mixed with chicory. They may be produced for less than 2d. per lb.

Elephant Pepper.—A larger variety of *Long Pepper*, which see.

The roots and stems, slightly dried, form the *Pippula moula*, a popular and stimulating medicine of the East Indies.

Elixirs.—See *Liqueurs.*

Elva or **Elvas Plums.**—A variety of dried prune from Elvas, the strongest fortified little town in Portugal (near Badajoz). They usually come packed in boxes, but also in tins of 1lb. to 4lbs. each, and are used as dessert fruit. Wholesale prices, 6d. to 10d. per lb.

Embden Groats or **Grits.**—(See also *Groats.*)—So called from being originally prepared at Emden (formerly spelt Embden), in North-west Germany, and consisting of oats which have been hulled or decorticated, and then broken or crushed into small flat pieces.

Leading Manufacturers. — Keen, Robinson & Co., Garlick Hill, London, E.C.

Emmenthaler Cheese.—A Swiss product, of large size, over 1 cwt. It consists of water, 45·2 per cent.; fatty matter, 28·2; caseine, 23·2; and salts, 3·4. An improvement has lately been made in the porousness of these cheese, but the soft parts are still very imperfect. This make of cheese is extensively imitated in Italy, Bavaria, and North-east Germany. (See *Swiss Cheese.*)

Emery.—F. *Emeri;* Ger. and Sw. *Smirgel;* It. *Smeriglio;* Rus. *Nashdak;* Sp. *Esmeril;* W. *Mwn haiarn.*

Emery Board, Emery Cake, Emery Cloth, Emery Hones, Emery Paper, Emery Powder, Emery Stone, Emery Wheels.

Emery itself, which derives its name from Cape Emeri in the Island of Naxos, is a hard granular mineral or iron ore of a bright grey colour inside, but of a dusky brownish-red outside, and next to the diamond in hardness. It is, however, neither more than less than an impure form of the mineral *corindum*, and the best. It ordinarily consists of about 86 parts of alumina, with about 3 parts of silica, and 4 parts of peroxide of iron, and 1 part not separated; and its value depends upon the nearness of its approach to pure alumina.

It is found mostly in amorphous or large boulder-like masses of no determinate shape or size, in several islands of the Greek Archipelago, particularly in Naxos, also in some parts of England, Germany, Italy, etc. Over 10,000 tons a year are now exported from Smyrna, where banks of emery are very common, particularly in the region of Anatolia, but they are only worked when near the railways, and the quality is inferior to that of Naxos. The plain and red Naxos emery, which contains neither gold nor silver, comes from the copper mines; it is therefore superior to that met with in iron mines, and which is of a blackish colour.

Although so hard a mineral as this can only be quarried with considerable difficulty, yet the methods employed in Greece are of the most primitive character imaginable. When a block is discovered it has to be broken up, so as to be carried more easily to the coast for export. Fires are, therefore, lighted round it, so as to materially increase any natural fractures or cracks which the stone may show. Steel levers and wedges are then employed till it is reduced to sizeable fragments for carrying on mule back. Naxos stone, in England worth about £4 a ton, is broken up and pulverised by machinery.

The Greek Government allows only the best stone, of guaranteed quality, to be exported, and this amounts to about 4,000 tons yearly.

In the preparations referred to the stone is first broken up and crushed to powder, and the powder is then sifted into various degrees of fineness, from the size of pepper-corns to flour or impalpable dust, which are carefully numbered according to the meshes of each sieve.

These powders, which are very rough and sharp, are afterwards stuck on boards, cloths, papers, etc., by first applying a coating of glue and then covering with the proper grade of coarse or fine powder.

Used for cutting, grinding, burnishing, and polishing purposes, with or without oil, by lapidaries, opticians, cutlers, masons, goldsmiths, locksmiths, glaziers, and other artisans in same way as glass paper.

An impalpable powder of Silica, made from a calcedonic rock in Vermont and used for the same purposes as emery, is sold under the name of American Polish.

Emery Board is made by mixing cardboard pulp with emery dust and then casting in cakes.

Emery Cake is composed of emery thoroughly mixed in melted suet and beeswax, and then forming it into solid lumps of suitable sizes.

Emery Cloth is a fabric coated with hot glue and then dusted with powdered emery.

Emery Paper is prepared in the same way.

Emery Stones are also formed of coarse emery powder, mixed with about half its weight of good Stourbridge loam and water, sufficient to make a stiff paste, which is then forced into a metallic mould by a powerful press. They are next exposed to almost a white heat. Sometimes the stone itself is worked with water, pressed into shape, and used alone without any admixture of loam.

The value of emery stone depends upon its abrasive power, the amount of work it will do on glass, steel, etc., before reduction to an impalpable powder which has no longer any cutting action. The abrasive powder depends almost entirely upon the percentage of anhydrous oxide of alumina contained in the mineral. Some—perhaps most—of the best emeries carry also a small percentage of titanates, but as the amount of these rarely exceeds five per cent. they may be left out of consideration. The principal impurities in emery consist of salts of lime and iron.

A practical way of testing emery is, therefore, to rub a plate of glass of known weight with a certain quantity until it has no further effect; the lighter the glass has become the better the emery.

For *Emery Wheels* only about a fourth of loam is used. (See also *Glass Paper* and *Sand Paper*.)

Enamel.—F. *Emaux*; G. *Schmelz*; Sp. *Esmaltes*.

This word is a corruption of the French term, *en email*. There are several descriptions of enamel. The ordinary kind met with is a semi-transparent or vitrified substance made of common glass, fused with oxide of tin, and is used in making dial-plates for watches, etc.

Enamel Paints.—These paints have come very much into vogue during the last few years, and are mainly used by amateur painters and artists, although a very large quantity are consumed by ordinary painters for surfaces where a very high polish is desired.

They are prepared from copal, kauri, and resin, dissolved in methylated spirits or shale spirit, are of all colours, and produce a hard and more lustrous coating than is left by paint, hence they are very popular for home uses.

Being professedly made to resist hot water, they are well adapted for painting baths, etc.

Special Firms.—Morris & Jones, 13 to 19, Sir Thomas Street, Liverpool (also special agents for *Maurice's Porcelline Co.*); Paton, Calvert & Co.'s "Komo" Black Enamel for Grates, etc., Leeds Street, Liverpool (see "*Komo*").

Enameline (Stove Polish). — See *Black Lead*.

Endive or **Winter Lettuce.**—F. *Chicorée*; G. *Endivie*; It. *Endivia*; Sp. *Endibia*.

This hardy annual, *Cichorium endivia*, is of the same genus as chicory, and native of the East Indies; but is cultivated as a garden vegetable about London, also more extensively in Holland and France.

In the latter country it is very popular, seasoned with garlic, and often eaten boiled, but generally the leaves are tied up, blanched, and used as a salad and garnish. It should always be crisp and succulent.

It used to be considered an invaluable antidote to scurvy, and was a fashionable vegetable in the time of Queen Elizabeth. Two distinct types or species are now cultivated, chiefly in market gardens and those of the wealthy; one is the curled form and the other the broad flat-leaved, known as the Batavian, and there are various forms of both, especially the curled.

ENDIVE AND FLOWER.

The green-curled kind is the principal one, as it best endures wet and cold; white-curled is, however, best for summer and autumn use. The *wide-leaved*, or Batavian, is mostly used in soups, stews, etc.

Endive requires much cleansing, as insects generally find their way right into the heart; but a dish of it well blanched and set round with slices of highly-coloured beet is very pretty. Some of the French selections of the *green curled* are extremely handsome, the leaves in some cases being most delicately and exquisitely cut.

Endive is chiefly imported, *viâ* Paris, from December to August. Prices, 1/- to 1/9 per dozen heads, and in tins of ½lb., 1lb., and 2lbs. each. Also from Holland, in hogsheads, price 30/- to 40/- each.

Epps's Cocoa.—It would be rather difficult to tell the majority of grocers more than they know about this familiar cocoa, for it has often been described by different writers, but the following notes, culled from various sources, may interest some readers. Although the cocoa only came prominently into public notice about 1850, few articles have ever attained such a wide popularity, and fewer still such a *lasting* success. We believe the mode of preparation owed its first inception to the late Dr. John Epps, Homœopathic Physician at the West End of London, who invented it for the special use and delectation of his clientèle. Its very agreeable character and beneficial results, however, soon spread, and attracted the attention not only of the Homœopathic world but of many of the most distinguished personages throughout the country. Mr. James Epps, the first Homœopathic Chemist established in this country (1839), and brother of the inventor, undertook its manufacture at his laboratory in Bloomsbury, and the allopathic public soon gave it the name of "Homœopathic Cocoa." In spite of the jealous feeling then existing in medical circles against anything *Homœopathic*, the demand rapidly increased, and necessitated a special establishment for its production. A steam factory was fitted up in the Euston Road, opposite the Marble Works, which have so long formed a landmark in that region. Here the business was, with frequent extensions, carried on for some 20 years, until its requirements quite outgrew the area available in that locality. It was no uncommon occurrence in winter for the factory to be a month or six weeks behind orders. In 1879 the present magnificent edifice, built and equipped

at a cost of something like a quarter of a million, was opened. Viewed at a distance, Epps's Cocoa Factory is seen to dominate the Surrey end of Blackfriars Bridge, almost as effectively as St. Paul's Cathedral does the Middlesex end. Whether the architect had this latter as his model or not we cannot say, but the resemblance has often been noticed.

In 1893 the firm, for family convenience, turned itself into a private limited company, with Mr. James Epps, the original manufacturer, at its head, and with Mr. Hahnemann Epps and Mr. James Epps, jun., as co-directors. It is under the assiduous management of these gentlemen that the business is still carried on. The chief aim has always been to produce the *highest quality* of cocoa, with all the nutritive elements of the bean in a thoroughly soluble form, so as to be easy of digestion. Unlike most other preparations of cocoa, none of the rich properties of the cocoa are abstracted, but the whole of the nib is, by Epps's method, utilised and made ready for the cup of the consumer. As is well known in Mincing Lane, only the highest qualities of cocoa beans are selected; no artificial flavours or colourings are employed; and the rest is left to the discernment of the drinker. Those who know best the individual attention bestowed on this cocoa say that greater pains could not be taken with it if every pound were for the Royal table! As may be imagined, such efforts are bad to beat, and the business still grows in various directions. It is probable that the export to the British Colonies and foreign countries now approaches, even if it does not exceed, the Home consumption. Indeed, large quantities of the prepared article go back to be drunk in the very countries where the raw beans are grown. The provincial grocer visiting London needs no "sky signs" to direct him to Epps's Cocoa Factory, for, amid the crowded city streets and noisy traffic, the grateful aroma pervading the air a mile around unmistakably announces the proximity of the familiar breakfast and supper luxury.

But, although no one has ever heard a word of complaint of the *quality* of Epps's Cocoa, there have been outcries about the smallness of the grocers' profits in selling it. Being a standard article at a standard price, well known to everybody, it has more than any other article been used by "Cutters" as a bait to catch customers. Instead of selling it at the moderately low rate of 1/4 per lb., several retailers, in competition among themselves, got it down some time ago to 1/1, and many sold it at a dead loss.

In response to numerous appeals from grocers that the firm should assist them in stopping this state of things and in maintaining a fair retail price, a plan was devised in 1896, and submitted for the individual opinion of about 100,000 traders in all parts of the Kingdom. By this plan 1/2 per lb. was suggested as the *lowest* price at which the Cocoa should be retailed. The replies in favour of that figure were practically unanimous, there being only about a dozen dissentients. Messrs. Epps at once decided to adopt the plan, and agreed to supply no one directly or indirectly who should sell below the minimum of 1/2. They also offered a special bonus of 2 to 3¼ per cent., varying according to business done, to all who faithfully carried out the rule. These conditions having been for the last four years firmly adhered to, irrespective of individuals or companies, the grocers' profits on Epps's Cocoa have considerably improved, and the retailer is enabled to secure about 15 per cent. Turned over often enough, this percentage should be fairly satisfactory!

Epsom Salts (*Sulphate of Magnesia*).—F. *Sels d'Epsom.*

Obtained from several sources, but originally as a saline efflorescence from certain bitter purging water-springs at Epsom, in Surrey—whence their name—and sometimes from sea-water. They are now chiefly made in the North of England from magnesian limestone, or dolomite, by treating it with dilute sulphuric acid.

Epsom Salts are very popular as a useful and mild aperient medicine, especially in feverishness, disorders of the liver, and in constipation, and they are considered a valuable antidote in cases of lead poisoning.

Epsom Salts are very cheap, but have sometimes been found adulterated with chalk, chloride of magnesia, and other substances.

They are usually packed in tierces, kegs, or bags, and should be kept in a dry place. It is a great fashion to buy them ready packeted, but these often get damp, stained, or soiled, and unsaleable, and it is best to keep them loose, and weigh up clean and fresh as required.

Erbswurst, or **Pea Sausages.**—A renowned make of German sausages invented by M. Grüneberg, who received £5,000 for the recipe from the Prussian Government. Said to be composed of a well-cooked purée of peas, mixed with a certain proportion of bacon or lard, seasoning, etc., and dried so as to be portable in a very small compass. It has been considered a unique food for supporting muscular activity and exposure to cold. This particular sausage owes its celebrity to the fact that it formed the chief food of the German army throughout the Franco-German war of 1870.

Ercoos or **Erquoos.**—A beverage made in Egypt from liquorice, and there used as are tea and coffee in England.

Ergot, or *Secale Cornutum*, is the fungus (*Claviceps purpurea*) of the diseased seeds of common rye. It is a purple-brown, or violet-coloured, spindle-shaped sclerotium, or compact mass of fungoid mycelium or spawn, from ½ inch to 1½ inches long, and entirely replacing the grain. Its use as a medicine was one of Hahnemann's discoveries, but when taken incautiously produces convulsions, gangrene, and death by poisoning.

Erunda. — A common East Indian name for the seed of the castor oil plant.

Ervalenta. — A botanical name applied to several compound cereal foods. The word itself is from *ervum lens*, signifying ground lentils or lentil flour. (See *Revalenta.*)

Warton's is said to consist of French or German lentil flour, mixed with either Indian corn or Durra (*Sorghum vulgare*), a species of corn largely grown in Arabia.

Some makes of Ervalenta are composed of the flour of French beans and Indian corn.

Eschalots. — Better known as *Shalots*, which see.

Eschalot Vinegar.—Generally made by infusing bruised shalots a few days in commercial acetic acid, and afterwards diluting with water to the strength required. It is used for flavouring soups and other dishes.

Esparto Grass. — Used in paper-making, and mostly comes from Spain and North Africa.

Essence de Portugal.—An essential oil made both at Nice and Grasse, in the Alpes Maritimes, from the skins of the bitter orange.

Essences.— (See also *Cocoa Essences*, *Flavouring Essences*, *Meat Extracts*, etc.)—The modern use of this term has a very wide significance, but in this country an essence is generally a solution of some fragrant essential oil with alcohol. The usual difference between an essential oil and essence thus consists in the essence being a *spirituous preparation*, whereas an oil is either expressed or distilled. It is, however, a common custom in America to call essential oils "essences," and hence confusion often arises. Essences are sometimes prepared by infusing the odoriferous parts of plants, etc., in rectified spirits, or by simply mixing the essential oil with rectified spirits. Essential oils, if very thin and clear, are very often called essences even in this country. Each kind is described in this book under the name of the substance from which it is derived.

Essential Oils. — F. *Huiles essentielles;* G. *Atherische oele;* Sp. *Aceites esenciales.*

These are the ethereal or volatile oily substances which occur already formed in the stems, leaves, flowers, or fruits of many aromatic plants, and give them their characteristic odour. They appear to be chiefly derived from certain orders of Rutaceæ, Myrtaceæ, Umbelliferæ, Compositæ, Labiatæ, Lauraceæ, and Coniferæ, but although thus confined to a relatively few natural orders, they are

found in all parts of the plants, and are obtainable by maceration, fermentation, and distillation with water.

They are called oils because they stain paper like oil, but under the influence of heat this stain, instead of increasing, disappears.

The most common sorts are the butter or oil of almonds, bergamot, carraway, cassia, cloves, nutmegs, lavender, lemon, mint, mustard, thyme, otto or attar of roses, etc. The generality of the plants yield their maximum of essence when they are dealt with in their fresh condition, but a few produce most when they are dry.

The substances are first either cut to pieces, incised, rasped, ground, or crushed, and placed in three or four times their own weight of water for macerating. After soaking 12 to 48 hours, according to their dryness or tenderness, they are ready for distilling. (Some light essences extracted from fresh roses and a few other flowers may be distilled without previous maceration.) The matter being placed in the still with the water in which it has been macerated, 15 to 20 per cent. of sea salt is often added to prevent boiling. (Salt water only boils at 229° F., but ordinary water at 212°.) Heat is then applied (either steam or fire heat will do), and the essence mixed with aqueous vapour is thus distilled. During the process the vapour of the oil to which the fruit or flower owed its odour has temporarily united with the vapour or steam of the water, but when cooled they separate, and the oil, now called *Essential Oil*, finally floats pure and colourless on the top of the water. The value or quality of essential oil is determined by diffusion and smell. Anyone thoroughly familiar with the odour of the pure oil may generally detect adulterations by letting a single drop of the oil fall on the back of the hand and then rubbing it about with a finger of the other hand. After the oil is partly volatilised, the odour may readily be detected.

Essential oils have always been an object of particular attention on the part of sophisticators; they are often adulterated with olive oil and others having the like odour, or even with alcohol and fatty oils, but the added oils may usually be detected by placing a few drops on a sheet of white paper and then drying it at the fire; if pure, no stain of oil will remain on the paper. If a resinous substance has been added, a small oily spot or stain will remain with a strong resinous odour. If alcohol has been added, this evaporation test will not discover it, for the spirit of course goes off with the heat, but if a few pieces of chloride of lime be introduced into the adulterated essence, these combine very readily with the alcohol and extract it from the essence. Another test for alcohol is quite as simple. The essential oil is poured into a tall narrow glass cylinder until it reaches a given mark. Then a quantity of water is added, and the whole well shaken together. If when the oil and the water are again separated, the oil occupies a less space than before, it is evident it contained alcohol, which is now combined with the water. Essential oils also often contain water, even though apparently clear, but by adding to a sample three or four times as much of petroleum ether of specific gravity 0·65 to 0·67, this speedily separates the drops of water, and renders the liquid more or less cloudy. When exposed to the air, essential oils absorb oxygen and soon acquire a consistency of resin.

The valuation of essential oils is incontestably one of the most difficult problems, for there are few chemicals so artfully sophisticated. A chemist cannot do much in detection unless his knowledge be supplemented in him by a highly developed sense of smell and taste. In some cases, indeed, a valuation is almost quite out of the question, since the most approved methods are of a very imperfect nature, and it is a curious fact that in many instances the chemical constituents upon which their value depends are not definitely known. In other parts of this book a few particulars will be found under the name of each oil. The Mitcham mint, lavender, and camomile oils fetch higher prices than any of foreign production. Large quantities of essential oils come from Alpine and Algerian flowers. Every season when

the Alpine flowers of lavender, spike thyme, etc., reach maturity a whole army of itinerant distillers with their apparatuses invade the Alps as far as the Piedmontese valleys to distil the oils. Essential oils, being soluble in alcohol, are now often made into *Flavouring Essences* for flavouring culinary preparations, also made into perfumes, scents, etc.

The essence industry in Sicily is both widespread and prosperous, and essence producers and exporters are numerous. Especially is this the case with the essences derived from the rind of all varieties of the citrus group, albeit they differ considerably in quality. That expressed from bergamot rinds is the best, then follow in order named lemon, orange, and citron essences, the relative values of the essences being in inverse order to that of the juices. Unfortunately, the essential oils are scandalously adulterated. Even after being analysed and sealed up, the coppers are often tampered with, and a portion of the oil replaced with turpentine through a little hole made somewhere in the solder line, where it can be closed up again without being noticeable.

But, in addition to the foregoing, we have also an ever-increasing class of artificial products passing in commerce as "Essential oils," or essences. Chemical research having discovered several compound ethers not yet known to occur in nature, but which, in conjunction with certain acids, are distinguished by smells so sweet as to entitle them to be placed among valuable essences, many of them have acquired a well-established place in the market, and have become articles of regular manufacture, under the names of Pear Oil, Apple Oil, Grape Oil, Pine-apple Oil, Essence of Melons, Essence of Quinces, etc. Potato ether is the base of most of them. (See *Pear Oil.*)

These artificial productions are now largely employed by confectioners, sugar boilers, etc.

Essential oils, essences, and perfumes should always be kept in close vessels well corked and from the light. Further details may be found in Sawer's "*Odorographia*," and in Power's "*Descriptive Catalogue of Essential Oils and Organic Chemical Preparations*," published by Frische Bros., New York.

For all kinds of Essences, apply to Charles Cocks & Co., Reading; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.; or Gio. Restuccia & Co., Messina, Sicily.

Essex Cheese.—A poor, hard kind generally made from thrice-skimmed milk, and very like to Suffolk cheese.

Ethiopian Pepper.—F. *Poivre de singe.*

A name given to the dried carpels of the fruit of the Xylpia aromatica, which is largely used as a pungent condiment in Central Africa.

Eucalyptus.—The Australian gum-tree which produces a medicinal oil and comes from Australia, South Africa, and Algeria.

Eugenia.— This is the fruit of the shrub *Eugenia* (*Myrtus*) *Ugni*, a native of Chili, where it is much esteemed.

It is the size of a large black currant or small cherry, somewhat flattened, globular, and crowned with persistent calyx teeth, brownish-red or glossy black, with an agreeable aroma. The pulp is light-coloured, soft, and juicy, with a sweet and spicy flavour, which is very pleasant to the palate.

The expressed juice, mixed with water, is a refreshing drink of aromatic odour.

Eulachon, Fish and Oil.—This fish belongs to the family of salmonidœ, and bears the scientific name of *Thaleicthys pacificus*, and is nearly allied to the capelin. The bays and estuaries of the Pacific coast of British America and Alaska are annually visited by immense shoals of them. They are popularly known as *Candle fish*, or adopting the vernacular name, as *Eulachon* or *outachon*. The Indian name is variously spelled *Eulachon*, *eulachan*, *hoolacan*, *ootachon*, etc., and is corrupted by the English settlers in Victoria as "hoolakins." One species is known in Oregon as "smelt."

This over-named fish is scarcely a foot in length, has a large mouth, pointed,

and conical head; colour, greenish yellow on back and silvery white on sides and belly. They are chiefly eaten by Indians, but make excellent pan fish, and, being very rich in oil, this is now "rendered" or manufactured, on the Naas River, as a substitute for cod-liver oil.

So rich in oil is the entire fish that when dried it serves the natives for torches, whence the name "Candle fish." Dried and salted, this fish has now become an important article of export from Victoria.

Evaporated Fruits. — (See also "*Dried Fruits.*") These generally appear very flat, thin, and shrunk, but having considerable absorbent properties they swell up surprisingly after being soaked a few hours in clean water.

The kinds of fruit most commonly sold evaporated are:—

Apples (American, the best). See *Apples*, also *Normandy Pippins* and *Norfolk Beaufins.*

Apple Rings and "Chops," or Sliced Apples.

Apricots in bags or boxes are very delicious when moderately cooked; Australians are the best flavoured.

Peaches, Raspberries, Cherries, Blackberries (three latter are better known in America), Pears, French and American (the latter being best and cheapest), Plums (stoned), etc., etc.

Fruit in order to be suitable for drying must possess the following qualifications:—The flesh must be firm and meaty and the juice rich in sugar in order to produce a heavy dried fruit, and the fruit should in no case be dried till thoroughly ripe, or it will weigh light and be of inferior quality. The following are some of the best drying fruits:—

Peaches, Free-stones. — Crawford's Early, Lady Palmerston, Muir, Salway, Crawford's Late, Susquehanna, Comet. Yellow-fleshed free-stone peaches having red at the pit are usually preferred, though any of the yellow cling peaches that are good canners also dry well.

Apricots.—The Moorpark leads, drying heavier than any other apricot, but all those mentioned as suitable for canning can also be dried. The Alsace, an apricot of the Moorpark type, is said to be giving great satisfaction as a drier and also to be a regular and heavy bearer.

Plums.—In addition to the various prunes used for drying, several varieties of plums dry well, the following being of especial merit:—De Montfort, Prince Englebert, Angelina Burdett, and Coe's Golden Drop.

Pears.—The best drying pear is the Williams' Bon Chrétien, as it retains its full flavour.

Apples.—The following varieties dry well:—Gloria Mundi, Granny Smith's Seedling, Cat's Head, Mobb's Royal.

"*Chops*" are apples sliced with the seeds, skins, and stems, dried and exported in old sugar barrels.

In boxing the fruit the layer intended for the top is put in first, an ornamental paper or lithograph is laid down, and covered with selected pieces of the fruit carefully flattened out, as it always pays to make the fruit look attractive as possible when opened. Peaches and apricots should be quite ripe when dried, whether peeled or unpeeled. The peeling is done either with the use of lye or by hand, after the fruit is sulphured. If with lye, a boiling solution of caustic soda—1lb. of caustic soda to 10 gals. water—is prepared, and the fruit immersed in it for 2 or 3 seconds, when the skin may be easily rubbed off. The peeled fruit must then be quickly rinsed in cold water, or the lye will turn it a dark colour. Smyrna figs remain on the trees till dead ripe, and are then dried in the sun without any dipping.

Dried Vegetables.—These are dealt with in much the same way, and large quantities prepared at Nice are exported from Bordeaux.

The economy in using evaporated or dried fruits and vegetables does not seem to have appeared to a good many persons. They think only of the trouble attending the selection and preparation of the fruit, and compare it with the ease with which the fresh fruit or the contents of a can are dumped in. But at all times good evaporated fruit is cheaper than canned, and when the latter is scarce and high, as it often is, and poor, too, the difference in favour of evaporated fruit is most marked. Here is a confectioner's way

of handling it:—"Select the fruit that you intend to use, rinse it thoroughly in clear pure water, then place the fruit to soak in an earthen dish, with sufficient hot water to cover it, from ten to fifteen hours before requiring it for use. Then place it on the back of the stove in the same water in which it has been soaked, which contains the flavour and nutrition soaked out of the fruit, and allow it to simmer slowly, just coming to a boil occasionally, until it is entirely cooked through; add sugar as the occasion requires to make it palatable. It can be served either hot or cold. As a rule, if it is placed on one side and allowed to cool it will be equally relished. By this method you will secure a wholesome and palatable dish, full flavoured, and resembling in appearance, size, taste, and flavour the original green product as near as is possible.

Most fruits are better and more valuable when evaporated by machinery than when merely dried in the sun, or even kiln-dried. (Much useful information on this subject appears in the *Society of Arts Journal* of May 1st, 1896, pp. 540-51.)

Everton Toffee.—Originally made, about 150 years ago, by Molly Bushell (née Margaret Cooper), Everton, Liverpool. It was in what is now known as Village Street, near the top on the left hand (where now stands the Wesleyan Chapel), that this person, in 1753, first made the toffee with which the names of Bushell and Everton are inseparably associated. Subsequently, a little lower down the village, Molly built for herself a new house and shop, which still remains, and where she continued to carry on the toffee and confectionery business, together with that of a small farmer. This kind of toffee is now manufactured by most confectioners, and is simply brown or moist sugar boiled in the usual manner with more or less of good or inferior butter, flavoured with lemon and run out in a sheet, from an eighth to half an inch thick. While warm it is either cut or marked out in squares, or it may be broken up when cold.

Exhausted Tea.—(See also *Maloo Mixture, Lie Tea, Tea Substitutes*, etc.)—The Food and Drugs Act, 1875, Clause 31, defines Exhausted Tea to mean and include any tea which has been deprived of its proper quality, strength, or virtue, by steeping, infusion, decoction, or other means.

The Inland Revenue authorities some time ago found a factory in London where *exhausted tea-leaves* were made to resemble good class tea. The manipulators of this ingenious swindle bought used tea-leaves from the large hotels and restaurants, "fired" and treated them by what was called the "Carrol" process, and sold the product to some of the largest packet tea firms in the country for admixture with genuine tea, and, although the Inland Revenue authorities knew the firms who perpetrated this fraud, they did not prosecute the packet tea merchants. We do not know why. It may be that we have a few Tammanys of our own, of which less is said in the English press than is written of the American one.

Extracts. — The term *extract* is generally applied to those preparations obtained by evaporating expressed juices, or the decoctions, infusions, or tinctures of vegetable or animal substances, until a mass of a solid, semi-solid, syrupy or fluid consistence is formed. Extracts differ from Essences, in that the former are less concentrated and usually contain water, alcohol, ether, or other matter, in which the base or extract itself has been dissolved. When water is employed, they are called *aqueous extracts;* when spirit is used as the solvent, they are called *alcoholic extracts.* When underproof spirits are used they are termed *spirituous extracts;* when acetic acid is employed they are distinguished as *acetic extracts.* Sometimes ether is used, and then the extracts are called *ethereal. Simple Extract* is a term applied to an extract prepared from a single plant, seed, fruit, flower, or other vegetable substance. A *Compound Extract* is one prepared from two or more of such substances.

Extracts and Essences of Meat.—See *Meat Extracts*, etc.

Extract of Herbs.— Mr. Adams, Mansfield, manufactures a concentrated preparation for making true *Herb Beer*, "composed of judiciously Selected Herbs, in combination with Hops. It contains in an admirable and attractive form valuable tonic, stomachic, and dietetic properties, and there is an entire absence of undesirable mixture in any form. It produces a beverage of high merit, refreshing, palatable, and wholesome." Extract from Analysis, by G. H. Sharpe, F.C.S. Supplied in 6d. bottles, sufficient to make 8 gallons.

Extract of Soap.—(See also *Washing Powders.*)—A fair quality is made as follows:—Soap, 14 parts; Soda Crystals, 30 parts; and water, 55 parts. The whole well mixed, dried, and pulverised. (This closely resembles Hudson's.)

Extractum Carnis. — See *Meat Extracts* and *Essences, Liebig's Extract*, etc.

Extrait d'Absinthe. — A liqueur made in Switzerland.

F

Face Powder.—An excellent face powder is made by mixing 23 parts Precipitated Chalk, 24 French Chalk, 7 Bismuth Sub-carbonate, 17 Zinc Oxide C.P., and 30 parts Corn Starch; perfume with oil of rose to suit. If it is desired to make it a flesh colour, carmine may be added.

Fachingen. — A German mineral water with acidulated, gaseous, and alkaline properties. It is a very pleasant and refreshing beverage, and is used in gouty and nervous affections, dyspepsia, heart-burn, etc.

Faham or **Fahran Tea.** — (Also known as *Bourbon Tea.*)—A name given in the Mauritius to the dried leaves of a fragrant orchid, *Angræcum fragrans*, which owes its odour to the presence of coumarin. It is a very agreeable drink, although less stimulating than ordinary tea.

The infusion is drunk to promote digestion, and is said to be useful in certain lung diseases.

Falernian or **Falernun.**—A liqueur made in the West Indies from rum, lime-juice, and sugar. It is prepared both white and brown, and may be used as a flavouring with any other kind of wines or spirits, also in soups.

Family Syrup.— This is a mere concoction of glucose and water, coloured and flavoured, to imitate Golden Syrup. "Amber Syrup" and "Table Syrup" are similar deceptions.

Fancy Soaps. — (See also *Soaps*, etc.)—Fancy soaps, mottled, streaked, or tinted, which are made in great variety for the toilet, are usually scented with some aromatic oils. For this branch of the trade the ordinary commercial or "stock" soaps are used, after undergoing a process of refinement, or a soap is especially made for the purpose from almond oil or the like. Much taste is shown by the best makers in the selection and combination of the perfumes, which, along with the colouring matters, such as vermilion, yellow ochre, aniline, etc., are usually boiled up with the soap. To facilitate this operation, as a well dried soap does not readily melt, it is usually cut up into fine shavings, and after warming is well worked under rollers until it presents a uniform appearance. If the soap is intended to be highly scented, or very expensive perfumes are to be employed, the cold process, known as "milling," is adopted, as much of the strength of the scent is lost by boiling. In this case the soap is shredded as before, and the perfume and colouring matters well amalgamated with it by being worked in a mortar with a pestle. It is then divided into lumps, and roughly moulded with the hand into something of the shape it is finally to assume. After being left on a rack to dry for about a week, it is pressed into a mould which

imparts to the cake the form and device which may be required, and when taken out the edges are trimmed, and the surface polished by hand with a cloth or piece of felt, moistened with spirit. In many cases exposure to wet steam for a few seconds develops on the surface a film or glaze possessing an admirable gloss without any further manipulation; but in the best soaps it is the natural result of using Naples soft soap as a base in the manufacture.

Most of these fancy soaps will be found more particularly described under their respective titles.

One of the judges at a recent International Health Exhibition wrote:—"To a great extent the public has only itself to blame, inasmuch as it persists in demanding articles to be supplied at prices incompatible with high quality, whilst it takes no pains to protect itself against the numerous frauds, adulterations, and misrepresentations thereby rendered inevitable, many of which would be punishable were toilet soaps and similar articles to come into the category of food, drink, and drugs, so that penalties would attach to the selling of goods under false names, such goods not being of the nature and quality demanded.

"It is true no particular harm is done to a purchaser of a cake of honey soap, should such soap contain no honey at all, as is usually (though not invariably) the case; but if an article is advertised as superior to others and sold at an enhanced price, on the ground of its being said to contain certain ingredients which are not present, as, for example, in the case of soap said to contain a high percentage of *glycerine*, or advertised as specially suited for application to the skin, because *sulphur* is an ingredient, when, in point of fact, no trace of sulphur or glycerine is present, it is evident that the purchaser is just as much damnified as he would be, were he to purchase 'bosh butter,' or margarine, at the price of genuine cow's butter, or were skimmed or watered milk sold to him instead of the unsophisticated article.

"That soap makers do not look at the matter from this point of view, however, is evidenced by the fact that at the International Health Exhibition, not one but several makers exhibited and supplied to the jury, for analysis, soaps stated to contain glycerine (in one case 30 per cent. being guaranteed), all of which were actually entirely devoid of that constituent, sugar being in some cases substituted for glycerine, in others not. Similarly, various other soaps were exhibited professedly containing certain other ingredients, notably milk, sulphur, arsenic, etc., all of which were really conspicious by their absence."

It may seem invidious after all that has been said and advertised about soaps (and what has not) to advise that if you have been out all day, or come from a journey, or if you have had a hard day's work, and you want to get thoroughly clean, don't wash your face with soap and water. Grease or oil is far better, as it enters and cleanses the pores of the skin. Learn a lesson from the actresses. If an actress were to wash with soap and water the nightly make-up from her face she would have no skin to speak of in a week, to say nothing of a complexion. Apply a little grease or oil, and then after a few minutes rub thoroughly, first with a soft towel and then with a piece of chamois leather. To demonstrate that this cleanses the skin more thoroughly, some day, after a journey, just wash your face with soap and water as well as you can; then cover it with grease or oil and remove with a soft cloth. One glance at the cloth will show that soap and water did not get it clean.

Apply to F. Newbery & Sons (English soaps), 27 and 28 Charterhouse Square, London, E.C.; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Farina. — (See also *Semolina* and *Fecula*.) — A Portuguese word for "meal." The term literally means the flour of any species of vegetable tuber, or starchy root, such as sago, tapioca, arrowroot, and sometimes includes rice, wheat flour, bran, semolina, or wheat pastes. The original was probably the powdered root of the plant Mandioca (which see), and is used largely in South America, where it is merely heated and

pressed into thin cakes like the oatmeal cakes of Scotland.

The name *Farina* is now ordinarily limited to a purified starchy powder made from potatoes. Price about fifteen shillings per cwt. The potatoes are first washed and peeled, then reduced to a pulp, and the fibrous matter separated from the starch by washing.

Apply to M. E. Holdsworth, 3 Norfolk Street, Bradford.

Farinaceous Foods.—See *Prepared Foods*, *Breakfast Cereals*, etc.

Farls, or Scotch Farls.—(See also *Oatcakes.*)—A sort of three-cornered oat-cake or biscuit, a thin circular cake of flour or oatmeal, being stamped by a stout tin cutter into quarters or thirds before baking. Originally called "girdle farls," from the fact of their being fired on a "girdle," or flat iron plate.

They are usually made in two sizes, halfpenny and penny. After being made they are laid down near the fire, when they assume a curled or curved shape.

Faro.—A cheap and inferior quality of Belgian beer, very popular about Brussels, where the consumption is from seven to eight million hectolitres yearly.

Farro. — Polish wheat, *Triticum polonicum.*

Fecula. — F. *Fécule.* (See also *Gluten.*)

The starch obtained (in the form of granules of different shape and size) from certain plants, seeds, tubers, and roots, by grinding them and washing them in water. The fluid is then allowed to stand a few hours, and the fecula, or starchy substance, settles to the bottom. When obtained from cereals or fruits this amylaceous substance is usually called *starch*, but fecula when got from potatoes, manioc, yams, and similar legumes.

Unlike sugar, *Fecula* is not fermentable until it be first made into sugar by the use of agents like sulphuric acid.

Fedelina. —(See also *Pastes.*)—A fine kind of Italian paste in a thread-like form, and of smaller size than vermicelli.

Feeding Stuffs.—F. *Engrais.* (See also *Poultry Foods.*)

There are many of these lines which might be taken up with advantage.

They are all legitimate and profitable commercial products, and, once started, will probably be found a permanent source of gain. They include:—

Bird seeds.	Locust meal.
Calf meal.	Maize (Indian corn).
Canary seed.	†Maltsprouts.
Cattle foods.	Maw seed.
Chick peas.	†Molasses.
*Cocoa-nut cake.	Molasses mull.
*Cotton-seed meal.	Oil-cakes.
Cotton-seed cake.	*Palm-kernel cake.
Dari seed.	Pig food.
†Dried beetroot pulp.	Poultry food.
†Dried brewers' grains.	*Rapeseed cake.
†Dried distillers' grains.	*Rice and rice-meal.
*Ground-nut cake.	†Rye bran.
Hemp seed.	*Sesamé cake.
Linseed.	†Wheat bran.
Linseed cake.	&c. &c.

Those marked * are often adulterated with weed seeds, obtained in cleaning grain before grinding, and which are often more or less injurious and poisonous—such as the seeds of henbane, spurge, crowsfoot, yellow-rattle, ergot, etc.

Those marked † should contain from 6 to 30 per cent. of protein, and up to 23 per cent. of fat; but they are often found adulterated with sand, talc, lime, oxide of iron, and manganese.

Care should also be taken (in buying or becoming agent for patent preparations) to avoid impure, adulterated, or injurious compounds, and fraudulent or useless manufactures.

Artificial "*cattle foods*," as a rule, consist mainly of powdered locust beans.

Feeding stuffs should each contain definite proportions of one or more of the following essential ingredients:—Digestible protein, fat, sugar, and extractable non-nitrogenous matter, and should at same time be clean and wholesome.

In purchasing, the guarantee of "pure" should be insisted upon, since this means a legal warranty that the article is produced from good clean seed.

The terms "best" and "genuine" are of no value, and should never be relied upon. The sample and bulk should be subjected to analysis occasionally.

Apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Feljoes. — Small beans, black, white, and variegated, mostly grown in Brazil.

Fennel. —F. *Fenouil;* G. *Fenchel;* It. *Finocchio;* Port. *Funcho;* Sp. *Hinojo;* Sw. *Fenkal;* W. *Ffenigl.*

An aromatic biennial herb (*Fœniculum capillaceum*), growing three or four feet high, with yellow flowers, cultivated in gardens as a pot herb, but is indigenous to the countries bordering the Mediterranean. Its soft thread-like leaves are boiled and served with salmon, mackerel, etc., as a seasoning. Its seeds possess a spicy agreeable flavour, and are used in cookery, and sometimes chewed by the country people in France and Germany. There are several varieties, more or less bitter, aromatic, or sweet. The young sprouts make a good salad. The seeds are long and very like anise fruit, but usually larger. The taste and odour are also similar. The German, French sweet, and the Indian seeds are the largest, and the Italian and Japanese the smallest. The latter are often sold as anise. The oil distilled from the seeds is largely used in the manufacture of cordials.

Fenugreek.— (Also spelt Fenugreck and Foenugraec).—W. *Y grog wyran.*

The seed of an annual leguminous herb, *Trigonella Fœnumgrœcum* (foin grec), or *Trigonia*, so called from *treis* (three) and *gonu* (an angle), in reference to its triangular fruit, nearly allied to clover, with flowers of delicate blue colour and odour like Balsam of Peru. This odour increases by drying, so that in Italy it is used largely by perfumers, and the Swiss use it to flavour cheese. There are several varieties, all containing more or less of Coumarin. It is largely cultivated in India as a fodder plant. The oily seeds have a peculiar smell and bitter taste. A flour made from it is used in veterinary poultices and as human food. Throughout Greece and the East the seed is eaten both boiled and raw, mixed with honey.

Fenugreek is generally imported in bags, and, when ground, is often used in mixing curry powders, also for giving a flavour to inferior hay. It is quoted on the London market, Egyptian and Mogador, 8/- to 15/- per cwt.

Fertilisers, Artificial Manures, etc.—These constitute an important adjunct to the business of country grocers, corn dealers, etc. There is now a very large and increasing demand for them, and they are worth careful attention. Many of them may be purchased ready for use, others may be easily prepared in an outbuilding by the dealer himself, and sold to farmers, gardeners, cottagers, and others, at remunerative prices. Most people now know that crops, like stock, grow only in virtue of the food that is placed at their disposal, either by nature or by art, and that, like animals, plants vary in their requirements. The sources of the food of crops, as is also known, are various. Rain or atmospheric moisture and the carbon that exists in gaseous combination in the air, furnish the great bulk of the food that builds up plants, but other portions of plant-food are derived from the soil. The country grocer should remember that the four principal fertilisers are, *nitrogen*, *phosphoric acid*, *potassium*, and *lime*, and assure himself that each manure contains a reasonable proportion of one or more of these ingredients. He might also ascertain what proportion of the above ingredients different plants take out of the ground, and in what fertilisers they are contained.

It is to be noted that only those ingredients which can be subsequently recovered in the crop, and which have been absorbed in the process of growing, are effective as fertilisers. For instance, phosphoric acid and potassium are the best fertilisers for turnips and other cruciferous roots, the first being especially valuable in helping the young plant through the most critical period of its life, and the latter an indispensable element in its after development.

For potatoes, turnips, and cabbage, phosphates and potashes are also important for productiveness.

Nitrogen is almost useless alone, but

becomes serviceable as an auxiliary. A mixture of 9 cwts., made up as follows, has been found to double a potato crop:—4 cwts. mineral superphosphates, 3 cwts. potash salts, 2 cwts. sulphate ammonia (contains nitre).

For *beans*, the best way to manure is to sow superphosphate; not only will it double or treble the bean crop, but will also more than double the succeeding crop of wheat, whereas beans, when manured even highly with stable manure, if they yield well themselves, leave nothing for the succeeding cereal.

Only a few of the numerous fertilisers can be noticed here:—

Mineral phosphates. — Florida high grade rock contains 75 to 80 per cent.; Carolina land rock and Peace River rock, 55 to 60 per cent.; Canada rocks, 60 per cent.; Belgium, also Somme and Osso phosphates are of high quality, and the prices vary from 7d. to 1/1 per unit of phosphate.

Bones and *bonemeal* mostly come from River Plate, Brazil, Mediterranean, and India, and are worth £4 to £5 per ton.

Liebig's guanos and English prepared fish guanos fetch about 8/6 per unit of ammonia. *Ground hoofs*, 8/- to 10/-. *Home prepared dried blood*, 8/- to 9/-. Imported, 8/6 to 9/6.

Powder for coating seeds, sulphated bones, saline mixtures, guano substitutes, clover and other special manures, raw bones or bone dust, should be bought as "pure," and should be guaranteed to contain not less than 45 per cent. of tribasic phosphate of lime, and 45 per cent. of ammonia. "Boiled bones" should also be guaranteed as "pure," and to contain not less than 48 per cent. of tribasic phosphate of lime and 1¾ per cent. of ammonia.

Dissolved bones vary so greatly that the buyer should insist on a guarantee of quality under the heads of "soluble phosphate of lime," "insoluble phosphate of lime," and "nitrogen," or "ammonia"; also for allowances at current prices for each unit per cent. if the bones should prove on analysis to contain less than the guaranteed percentages, etc. It should be insisted that mineral superphosphates be delivered dry and in good condition, and be guaranteed to contain a certain percentage of soluble phosphates at a certain price per unit per cent. No value is to be attached to "insoluble phosphates." Compound artificial manures which are rarely used should be purchased on exactly the same terms.

Nitrate of Soda should be guaranteed to contain 94 to 95 per cent. of pure nitrate.

Sulphate of Ammonia should yield 35 per cent. of ammonia.

Peruvian Guano should be sold under that name, and guaranteed to be in a dry, friable condition, and to contain a certain percentage of ammonia. (See *Guanos.*)

Foodite, intended for horticultural purposes is the marc left after the second extraction of castor oil from the seed. Analyses have shown it to contain 7·28 per cent. of nitrogen, equivalent to 8·84 per cent. ammonia.

In buying artificial manures, the purchaser is recommended to obtain a guarantee that they shall be delivered in a sufficiently dry and powdery condition to allow of sowing by the drill. Samples taken out of three or four bags should be mixed together and analysed not later than three days after delivery. Two tins, holding about a half-pound each, should be filled in the presence of a witness, sealed up, one sent to the analyst, and the other retained for further reference.

Fiji Tea. — There are now about 460 acres planted with tea in this island. (See *Tea.*)

Fig-Tree Wax. —A vegetable wax obtained from Java.

Figs. — Ar. *Teen;* Da. *Figen;* Du. *Vygen;* F. *Figues;* Ger. *Feigen;* It. *Fichi;* Pol. *Fiki;* Port. *Figos;* Rus. *Winnua jagodi;* Sp. *Higos;* Sw. *Fikon;* W. *Ffigys.* (See also *Elémé Figs.*)

The fig (*Ficus carica*) appears to be the oldest of historical trees, and is frequently mentioned in the Bible: Deut. viii., 8; 1 Kings iv., 25; Solomon ii., 13; Jer. v., 17, etc., etc. It

was the flavour of Athens figs that tempted Xerxes to undertake the conquest of Attica (Greece) in 480 B.C.

FIG-TREE AND FRUIT.

There are about 300 varieties—green, white, yellow, brown, and black. Figs are native of the Mediterranean region, Syria, Eastern Persia, to Afghanistan.

They were cultivated in China as early as the latter part of the 14th century. They now abound in all warm climates, like India, Asia, Africa, and Southern America, and the common fig-tree is now cultivated all over Southern Europe.

It grows 15 to 30 feet high, with dark-green leaves, rough above and downy beneath. The spores are of very dark violet colour, smooth externally, globose in form, and measure 6 to 8 inches in diameter. The tree in all its parts abounds in a viscid milky juice, even in the unripe fruit.

This juice is very acrid, and is said to destroy warts, and in Pliny's time it was thought to cure the bites of venomous animals and mad dogs. The flowers are never apparent to the eye, but are contained in those fruit-like bodies produced in the axils of the leaves, and it is not until one of these is opened that the flowers are visible.

What is therefore termed the fruit is merely the enlarged fruit-stalk end, which has become fleshy, and assumes the form of a hollow body, bearing on its interior wall the flowers or fruit of the fig.

These pear-shaped fruits grow out of the limb twice, and in some places three times, a year—in June, September, and a later imperfect crop in December, but this last is very precarious.

The pulp of the fig contains over 60 per cent. of sugar. The largest and best come dried and pressed into layers in drums or in small square wooden boxes of ¼lb. to 14lbs. each, from Smyrna, in Turkey, the finest being known as Elémés (see *Elémé Figs*), new crop arriving in latter end of August or early in September. Usually packed in *skeleton cases* holding 2½ to 3 cwts. Others are pressed into bags of 14lbs. to 60lbs. each, also in mats and baskets.

Rush baskets, called "*tapnets*" are often used.

Figs are dried either in the sun or in stoves, and are usually known by the names of the places where produced.

They form the greater part of the food of certain peoples in Africa, and even the peasantry in some parts of Spain and Italy.

Three pounds of fresh figs yield only about 1lb. of dried figs.

Those from Greece are usually very small in size, very much dried, and packed in barrels or baskets, also threaded upon long rushes or *bass* strings, and not so carefully packed as Turkish—which, indeed, are the chief growth inported into England.

Faro figs commonly come in tapnets of 28lbs. and boxes of 22lbs.

In Spain figs are largely exported in mats from Malaga and Valencia, and they are more or less abundant in every province. The number of fig trees in

the Lepe and Cartaya district exceed 400,000, and produce some 2,000 tons yearly. The export from Huelva is, however, now very small, and most of them are shipped from Cadiz, whither they are sent in faluchos from Cartaya. In quality these figs are much inferior to Smyrna figs, and are principally used for cooking with rice or for making into fig cakes. All Spanish figs have a bluish cast, with a sweet and agreeable taste, but the skin is hard and thick.

In Syria, and throughout the Levant, figs are grown in great abundance, and form the chief food of the soldiers and native inhabitants.

They are medicinally a mild laxative, but (unless packed with a good supply of bay leaves) those dried entirely in the sun are frequently infested with small grubs.

The cheaper kinds, commercially known as "naturals," usually arrive in 56lb. bags or cases. They are liable to be affected with "fig smut," a reproductive parasite which commences work in the interior of the fruit, and soon converts the whole into a sooty mass.

This insect, known as the *Coccus Rusci*, is especially partial to the fig, but it is also found on other trees. The diameter of a well-developed female is five millimetres, their colour is a greyish-white, and they have the appearance of small cones upon the trunk and boughs of the tree. They cover themselves with a special substance like wax, which protects them. If this is removed with a needle the true colour beneath is seen to be a shiny reddish-brown, this being the creature's true cuticle. Raising the skin, a vast number of eggs will be observed (if the operation is performed towards the end of June), these eggs being of a reddish-brown colour. They become larvæ in the month of July, and in a few days, when they drive the proboscis into the bark, they manage to nourish themselves from the tree. Once fixed, they undergo a strange metamorphosis, for their legs drop off, their eyes disappear, and their bodies exude the waxy substance which serves them as an ultimate protection. No insecticide will affect them when once they are duly encased; but before that takes place they can be killed by syringing the trees with a solution of petroleum and soda crystals. This must be done as soon as the larvæ appear, and it will completely destroy them.

Figs are best when thoroughly ripe and not gathered till they drop from the trees, the skin slightly cracked, and the exuded juice adhering on the surface like dewdrops.

Figs are generally gathered and cured as follows:—A sheet is held under the tree, then the branches are shaken to make the ripe fruit fall. Any bruised fruit is not fit for curing. A bath of strong potash lye is prepared, strong enough to float an egg, and when boiling hot the figs are dipped into it by means of a wicker basket for the space of two minutes, and then again dipped in clear water. After dripping for a short time they are fit for drying, either in the sun or in ovens or machines. The figs may then be flattened by pressing with the hands. The sun is best for drying them; but, as already stated, flies are apt to lay eggs in them, and they may afterwards become wormy. The heat of an oven, on the contrary, is hot enough to destroy the eggs.

Pulled Figs, from Turkey, fetch the highest prices obtained for the dried kinds, and when honestly packed are decidedly the best; but there are packers who, having arranged to receive liberal advances for their products against shipping documents, are tempted to use best fruits for the top layers only, while the underneath consist of the inferior figs termed "naturals." Very few grocers notice sufficiently the costly way the finest qualities are packed.

Italian Figs are among the latest novelties. The come over in excellent condition, and (being of very fine flavour) are easily retailed at 1d., 2d., and 3d. each, according to size and appearance.

American Crystallised Figs are also of recent introduction. Being preserved in a soft fresh state, they are very delicate and highly esteemed. Usually packed in ornamental boxes containing half a gross of fruits.

French Figs.—There are also several fig gardens in the south and west of France, especially about Argenteuil and in Roscoff (Finistere), but the fruit is eaten fresh and never dried.

The blue fig, or *Violette de Bordeaux*, familiar to visitors to the Riviera, is also grown in Kent, and often makes its appearance in our markets in October and November.

Indian Figs is a name often applied to *Prickly Pears.* (See latter.)

For figs and other dried fruits apply to Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

corruption of their original English name of "*full-beards*," and sometimes called Jerusalem filberts. See also *Cob*, *Hazel*, and *Barcelona Nuts.*)

These are one of the best species of the English hazel nut, *Corylus avellana*, cultivated in Kent and in a few other districts. It was grown in Wiltshire as far back as 1810, but was probably first improved in Italy, Spain, or Palestine by superior soil, climate, and culture.

This nut may be easily distinguished by its elongated form, and by the lacerated and contracted form of the involucre or skinny envelope in which it grows. As with other kinds, that sort which has the pellicle which covers the kernel of a deep red colour is the most esteemed. Enormous quantities are grown in Tarragona, Spain, but

Fig Dust.—A name among mealmen for fine ground oatmeal, sold for feeding caged birds.

Figuera. — A kind of spirit distilled from fermented figs in the Levant, Portugal, and the Canary Islands.

Filberts. —F. *Avelines;* G. *Lambertsnüsse;* W. *Cneuen ysbaen.* (A

they reach their greatest perfection in England.

After gathering they are usually laid in an airy place in the sun for a few days to dry the husks, which are generally moist at the base, then packed in tin boxes about 10 inches long, 6½ wide, and 3½ deep. After the lid is put on a strip of paper is pasted round

the top to keep it air-tight, and then stored away in a cool, dry place. Retailers often keep them in dry sweet casks and jars, and sprinkle a little salt among them to prevent mould and keep the kernels crisp. If the husks lose their colour it may be restored by holding them in a sieve over sulphur fumes, produced by burning a little sulphur over a small clear charcoal fire.

Filberts grown in the hop districts are often gathered green as soon as the kernels fill the shell, so as to have them cleared away before the hop pickers arrive; but the nuts are best left until September or October, when they fall on shaking the trees. They are then picked up, as already explained, by women and boys, spread about 9 inches thick on a boarded floor, and turned over occasionally to prevent moulding. In this way they may be kept a long time, but they are mostly marketed in December or February. They are often packed in sieves of 7 gallons each, just as they grow, with the husk on, and covered with paper, straw or coarse hay being spread over it, and this is kept in place by sticks. In Covent Garden filberts and cobs are sold by the 100lbs. (4lbs. extra being given), or else per lb., cwt., or ton.

Filbert plantations exist on a large scale in Sicily, near Piazza, Armernia and Aidone, in the province of Caltamssetta, and Palagonia, province of Syracuse. They are also cultivated in large quantities in the regions of Etna, in the valleys between Linguaglossa and Cartiglione, Randazzo, and Bronte.

Filberts are more wholesome and free from oil than any other nuts of the kind, and are considered to be in season from September to March.

Field Cheese. — See *Margarine-cheese.*

Fin, or Fins.— The singular and plural forms of the French word *fin*, meaning "fine" or "small." (See also "*Shark Fins.*")

Finings for Liquors.— F. *Clarifiants;* G. *Klaermittel;* It. *Chiarificanti;* Sp. *Clarificantes.*

Mostly made by softening isinglass with sulphurous or tartaric acids, sometimes both. If served when unready, or if treated with too much acid, little strings or shreds appear, and will neither rise to the top nor sink to the bottom, and will cause great complaints. These are chosen because they are reasonably quick in action, contain no disease germs, and are not liable to acidify the beer.

If tartaric acid be used, the crystals should first be dissolved in boiling water, say 1 oz. of crystals for each pound of isinglass; if sulphurous acid be used, 1 gallon of 5 per cent. strength for 7lbs. of fining material, the isinglass being first soaked in cold water for 24 hours before adding the acid. The isinglass must be kept covered with liquid (if for fining ales sour ale may be used) and well stirred at least once a day. In about a month it should be dissolved, and free from any but the smallest and softest lumps, and should then be passed through a hair sieve. Finings should be kept in a cool place and well covered with sacking cloth, and on top a lid.

One pint of finings should suffice to clear a barrel of ale, cider, porter, etc., and a quart for a hogshead of wine. Good finings should dissolve perfectly in water, and leave no more residue than sugar does. Finings for refining and clarifying ales, wines, vinegar, syrups, cordials, etc., may be made as follows:—

Isinglass will not dissolve in any cold liquid that does not contain acid. The quantity to make ½ gallon of finings should be only ½ oz. of isinglass.

1. Dissolve ½ oz. acid in a pint of water, then put in the isinglass, and as the matter swells keep adding water until the quantity reaches ½ gallon. This will be sufficient to fine 5 gallons of wine. Of course, this refers to real isinglass; if gelatine or *imitation* isinglass be used failure will result, because these articles do not possess fining power.

2. For *gin*, take 4 oz. subcarbonate of potash and 8 ozs. roche alum. Mix in powder.

3. *Clarifying Powders*, for red wines, etc., are also prepared from dried blood albumen, and sold at about 5/- per lb., half an ounce in a pint of water sufficing for about 40 gallons of wine.

4. Finings *for syrups* are sold ready prepared by wholesale druggists, etc., from 9d. to 1/9 per lb. One ounce dissolved in a pint of water should be added to 20 gallons of syrup before boiling. For cordials 1lb. suffices for 100 gallons.

The action of the finings seems to be purely mechanical—the gelatinous matter, slowly settling to the bottom of the vessel, carries with it the insoluble substance which has caused the turbidity.

Finnish Butter.—Five years ago this was considered very inferior, but latterly the quality has vastly improved. It was exported from Finland in 1898 to the value of 26,998,000 Finnish marks (about £1,080,000), the value of the exports to the United Kingdom being 15,643,250 marks (about £626,000). The total quantities exported were:—In 1896, 273,200 cwts.; in 1897, 286,000 cwts.; in 1898, 243,200 cwts. In 1899 the quantity exported is stated to have increased considerably, and the St. Petersburg "Zeitung" says that the quality of the butter has improved so much that Finnish butter is now ranked as high as Swedish on certain markets. Measures are being taken in Finland to assist the butter trade; in particular, Finnish steamers and railways are being provided with apparatus to keep the butter at a low temperature. It is intended shortly to inaugurate a regular weekly service of steamers between Hull and Finland; this service will be maintained in winter *viâ* Hango.

Fir-tree Oil. — An insecticide obtained from the Corsican pine (*Pinus laricio*), and to be mixed with water. It is sold in bottles, 1/6 and 2/6 each, and also in gallon jars about 10/- each.

Fire Lighters, or **Kindlers.**—F. *Allume-feux.*

1. The pieces of wood are usually dipped in the commonest liquid resin.

2. Some are dipped in a composition made of 60 parts of melted resin and 40 parts tar.

3. Melt 8 parts of resin, then add 1 part tallow, stir up, and dip each piece of firewood in the composition.

4. Same as above, add as much sawdust as can be worked in, and then form into blocks or bars, suitable size.

5. Excellent firelighters are made by agglutinating the husks of cotton-seed with melted resin.

Special Manufacturers.—Fitch & Sons, Tamworth, makers of the "Fox and Firebrand" kindlers.

Fish (Dried, Salted, and Smoked).— The preserved fish ordinarily met with are barrelled cod, dried salt cod, smoked haddock, ling, salmon, red herring, kippered herring, bloaters, and dried sprats.

The curing is not confined to large establishments, but is also done on the premises of petty vendors all the year round. Fish that is already stale and just beginning to turn is put into the brine tub for a few hours, and then rapidly smoked, sun-dried, or wind-dried. Thus cured, the fish is often bad and unwholesome, and the superficial curing merely hides its defects. Even fresh fish, if cured so quickly, would not keep good very long.

Foods rich in phosphorous, such as fish and the like, have long been held by certain people to be "good for the brain." Some have even gone so far as to declare that the brains of mankind in general are capable of being permanently strengthened and clarified by a specially prepared phosphoric dietary. But it has never been scientifically demonstrated that fish and other phosphoric foods can appreciably improve the brain and mind. Fishermen, for example, and fishmongers, who may be supposed to live largely upon fish, have never shown themselves to be in any measurable degree more intellectual than their neighbours. Indeed, it may be plausibly argued that they are a little less so. The truth is, that that

particular food which best agrees with the particular individual, and which best maintains his general health at a high level, is the best for the brain and every other organ of the body, as well as for the whole man. Common experience has long ago formulated the saying that "what is one man's meat is another man's poison." Science now comes forward to tell us exactly the same thing, and to impress upon everyone of us the necessity of finding out the diet best suited to ourselves, and sticking to it.

Flageolets, (Haricot Flageolets). —The French name for the young green and tender seeds of the finest variety of *French bean* (*scarlet runner*) or haricot bean, gathered and shelled before turning white. Flageolets are generally sold in small bottles or tins labelled as "*très fins*" (very fine or choice). When mixed in about equal proportions with the immature green pods they form the very fashionable dish known as *Haricots verts panachés*. Flageolets are also sold dry as well as in brine.

Flaked Cocoa. — F. *Cacao en feuilles.* (See also *Cocoa, Manufactured.*)

A name given to drinking-cocoa which has had a fancy or flaky form given to it by a mill consisting of two cones, one working inside the other.

It is a mistaken idea to suppose, as some do, that flaked cocoa is essentially pure, it very rarely being so, but is usually flaked after mixture with sugar and potato starch, sago flour, or other farina. When an excessive proportion of these additions is made, colouring matter also becomes necessary to disguise them.

Flaked Oats. — See *Avena Flakes, Rolled Oats,* etc.

Flash. — A compound concocted from essence of capsicum (or cayenne) and burnt sugar (or caramel), for adding to weak spirits to make them taste strong and fiery. Say ¾ pint of fluid extract of capsicum in 1 gallon of burnt sugar colouring.

Flask Oil. — (See also *Salad, Florence,* and *Olive Oils,* etc.).—This is, or should be, olive oil, put up in thin glass bottles, which are usually ornamentally wickered, and hold from 6 to 16 ozs. of oil. The oil is imported from Italy in "chests" of 60 and "half-chests" of 30 flasks.

These flasks, when empty, are often usefully made into retorts or receivers, such as are required for chemical experiments.

Flavouring or Culinary Essences. —(See also *Essences.*)

The following are the principal sorts put up:—

Allspice.	Garlic.
Carraway.	Ginger.
Cardamoms.	Lemon.
Cassia.	Mace.
Cayenne.	Marjoram.
Celery seed.	Nutmegs.
Cinnamon.	Orange.
Cloves.	Peppermint.
Coriander seed.	Spearmint.
Fennel.	Sweet basil.

These are prepared for the use of cooks, confectioners, liqueur and cordial makers, etc., in flavouring soups, gravies, sweetmeats, pastry, wines, liqueurs, cordials, etc.

The essences may be prepared by either dissolving 1 fluid ounce of the essential oil of the particular substance in 1 pint of rectified spirit, or by digesting from 4 to 6 ozs. of the bruised spice, or from 5 to 10 ozs. of the dried herb in a like quantity (1 pint) of spirit. The first method is the best, least troublesome, and yields the finest quality.

Such essences are commonly labelled "Concentrated essence of ——," or simply "Essence of ——."

Cheaper kinds are made from half the above proportions, infused in a pint of proof spirit or British brandy, and sometimes "shot whisky," instead of rectified spirit.

Penny bottles of Almond Essence (bottles, 12 to the ounce) are commonly put up by mixing and shaking together a pound of essential oil of almonds, a pint of spirits of wine, and a gill of water.

For *Lemon Essence.*—A pound of sential oil of lemon and a pound of ear cotton-seed oil. Let this stand ll clear before bottling.

Special Firms for Essences.—Charles ocks & Co., Reading, Berks; Morris Jones, 13, 15, and 17 Sir Thomas reet, Liverpool.

Flax Seed.—See *Linseed.*

Floating Soap.— This soap is a ry pretty toilet variety. It is usually ade of good ordinary wax-grain or coa-nut oil soap and water, in the oportion of 14lbs. soap to 3 pints of ater, melted, and while warm is easily aten together in a vessel containing sh wheels, and agitated until it is npregnated with bubbles of air, and ade quite light and double the iginal volume of the soap.

This lightness and buoyant character nders its use advantageous in baths, ., and gives the soap its name. It is dinarily coloured with a little vermilion, d perfumed. Floating soaps, however, ssess no other special characteristics atever, and the question is whether e fact that they will float compentes for the buying of air instead of ap.

Floor Wax or **Polish.**—Often a eparation of turpentine and beeswax, d retailed in 1/- or 5/- tins.

Examples:—1. One hundred pounds paraffin are melted and then mixed th 150lbs. of colophony. When the o are thoroughly melted and mixed gether, 10lbs. of hot olive oil are oroughly amalgamated with the mass. ne stuff is then poured into moulds d allowed to set.

2. Hard paraffin, 3,710 gm.; powred boric acid, 450 gm.; lavender , 4 gm.; neroli oil, 20 drops. The raffin is melted and the other comnents are carefully added.

3. Six parts of hard paraffin and 2 rts of yellow wax melted and mixed, d coloured with powdered turmeric.

4. One kilo of yellow wax, 1½ kilos oil of turpentine, and a little spike .

5. Two kilos of yellow cerisin, half a o of liquid paraffin, 1½ kilos of French oil of turpentine, and 2 kilos of benzine.

Waxed Colours for Floors.—(1) Yellow.—Seven and a-half pounds of caustic soda lye and 2½lbs. of yellow wax are boiled together, and then mixed with 2lbs. of finely powdered ochre, and stirred into a uniform mass. (2) Nut Brown.—Substitute umber for the ochre in the above recipe. (3) Reddish Brown.—To the above quantities of lye and wax add ½lb. of Orleans, 1lb. of burnt umber, and 1lb. of yellow ochre. All these mixtures are applied in the following manner: First brought to the consistency of a thin syrup with hot water, they are brushed on with a stiff brush, and polished when dry. One coat is generally insufficient; a second coat usually has to be applied in the same manner. Too much surface must not be covered at a time, as the stuff dries too quickly. The polishing is done with a stiff brush and finally a woollen cloth.

Florence Oil or **Cream.** — See *Olive, Flask Oils, Salad Creams,* etc.) —Once an esteemed and superior quality of Italian olive oil, prepared in Florence, and exported in flasks, but now rarely pure.

The Tuscans were the first to export olive oil largely, and thus arose the name "Florence Oil." (See also "*Tuscan Oil.*")

Florida Oranges. — (See also *Oranges.*)—The Riverside, Washington, and Navel varieties are the most popular. Crop now 4,000,000 to 5,000,000 boxes a year, but ten years ago it was only some 600,000 boxes.

The earliest varieties are eatable in September, and in fact most fruits are a month earlier in Florida than in any other State in the American Union.

Owing, however, to tenderness of skin, Florida oranges travel badly, and the cost of transit to England militates against a large trade.

Florida is about three days' distance by quick train from New York, and the oranges often get frostbitten in

transit, which imparts a dark brown leathery colour to their skin.

Florida Water.—F. *Eau de la Floride.*

A colourless toilet fluid, like Eau de Cologne. This refreshing Eau de toilette has usually a spirituous, not an aqueous, basis. Although not so well known in England as Eau de Cologne and Lavender water, it has a much larger sale in the U.S., and affords a pleasant change.

Import duty 17/3 per gallon.

Importers.—F. Newbery & Sons, 27 and 28 Charterhouse Square, London, E.C.

Floriline.—This is a popular tooth-paste, usually sold in quadrangular china pots. It is a red, dry, and rather hard mass, made from prepared chalk, 20 grms.; starch powder, 10 grms.; pellitory tincture, 3 grms.; peppermint oil, 10 drops; and water; and is coloured with Florentine lac.

Flour.—Da. Du. *Meel;* F. *Farine;* Ger. *Mehl;* It. *Farina;* Port. *Farinha;* Rus. *Muká;* Sp. *Harina;* Sw. *Mjol;* W. *Blawd, Can, paill.* (See also *Self-raising Flour.*)

Flour is better if kept a short time after being ground before it is made into bread. A fair idea of the quality may be formed by pressing a portion of the flour between the thumb and fore-finger, and at the same time rubbing it gently in the hand for the purpose of making a level surface on the flour. If the latter feel rough, loose, and lively in the hand, and will not form a ball, it is generally of good quality, and shows that not much (if any) of the best parts have been taken out; but if it feel dead, woolly, damp, or clammy when rubbed between the fingers, or if it form into beads or peas when laid on a sheet of paper and shaken about with a circular motion, it is bad, and is probably a damaged or residue flour from which the best has been taken. If, however, a handful be taken up and grasped firmly, good flour will retain its solidity and form on being laid down.

Roller-milled Flour.—Modern mills with steel rollers can now separate the grain into nine varieties of flour and three of bran, the fineness decreasing from Nos. 0 to 9, and it is clear that the finer the flour the less of nitrogen and more of starch. Fine flour is also less digestible than coarse. The roller-milled flour has a richer and better appearance, but the old stone-milled makes sweeter and better bread. (See *Bread.*)

Dry foreign wheat cannot well be ground in the old stone mills, which are the best for grinding our English wheats, and to meet the demands of bakers many millers have replaced their millstones with iron rollers, which will not grind the soft English wheats well; therefore, roller millers are very poor purchasers of home-grown wheat, and thus the price appears to have been reduced.

Flour made in stone mills consists of small pieces of the husk, portions of the germ or vital part of the grain (these discolour the bread in baking), and nearly the whole of the kernel. Flour made in roller mills consists of portions of the kernel alone; the husk, the germ, and most of the outer parts of the kernel being removed in the various processes of roller milling, and these are the most nutritious parts of wheat. Another and more important point, however, with British millers and bakers, is that a 280lb. sack of dry foreign flour will absorb 64 to 72 quarts of water, while English growths, being already full of moisture, will bear no such profitable addition.

Colour is regarded by bakers as the chief criterion of quality, and leads to many disputes. It should be white, with a yellowish, straw-coloured tint. It should not be very white nor with a bluish cast, nor with black specks in it.

The successful baking of a flour does not depend entirely on its quality. The very best flour will, under some conditions, and manipulated by careless breadmakers, produce an inferior loaf.

There are certain conditions which control the quality of the bread; for instance, the temperature at which the

flour is kept. Flour should not be exposed to an extremely low temperature, but should be kept, if possible, in a cool, dry, and airy room, at a temperature of about 70° Fahrenheit.

Flour should not be stored in a room with goods that have a strong flavour or odour, such as coal, oil, tobacco, coffee, fish, or stale vegetables, for it will absorb these odours and retain them when in the form of bread. Through this cause flour is sometimes pronounced unsound.

Age will whiten flour, or, as we say, bleach it out. Some claim that old flour loses its natural flavour and nutritive quality to a certain extent. If this is true, why is it that old wheat flour brings a premium over new wheat flour at harvest time? If the new wheat is sound and well-matured it would certainly have all the flavour and nutriment possible; still, it is not wanted by the large flour buyers. Flour from two months to one year old will not have lost any of its flavour or good bread-making qualities, if properly kept.

Inferior flour has a dull white colour, and a soft, weak-bodied flour has a smooth feel, like soapstone. Strong flour, as a rule, has a granular or sharp feel when rubbed between the thumb and forefinger. Strong flour will absorb more water, make a larger loaf, have a better flavour, and contain more nourishment than a soft, weak flour.

It is well to remember that samples of flour kept long and exposed to the light become bleached and much lighter-coloured than they were at first.

Complaints are often made that flour has gone sour. This has been caused by the dampness of the wheat from which the flour was made, and probably by improper management of the flour immediately after being manufactured. When the flour is "hot off the mill," that is, directly after it has been made, there is perceptible warmth in it, and unless the flour is cooled before being put into a barrel or bin it will not keep sweet and good, but becomes lumpy, which is a sure sign that it has not been properly managed. Flour is all the better for being kept in the sack for the first week, the sack being laid on a dry board floor, and turned underside up every day till it gets cool; it may then be put into a barrel, but requires turning with the scoop at least once a week afterwards.

Flour that has been exposed to the sun will not make good bread. It has been proved by numerous experiments that flour cannot bear the action of the sun, even when not exposed directly to its rays. When flour is exposed to the heat of the sun an alteration takes place in the gluten similar to that produced by the heating of the stones. For this reason it is advisable that the transportation of flour should take place, if possible, on cool days or by night, as well as that flour should be stored in a cool place, says a milling paper.

Baking flour should not be too fine, for being less vaporous it bakes much harder than coarse. Good flour always has a yellowish tinge. A good test for the best flour is to knead singly a given weight of each sample of flour with half its weight of water. The best flour will produce the stiffest dough.

Hungarian Flours.—The term "Hungarian" is extremely vague, as there are as many grades of Hungarian flour as of American, or any other. Speaking generally, therefore, Hungarian is of good colour and flavour and passable strength. The higher grades contain all that can be desired, and are the best flours of the world; the lower and intermediate grades are weaker and likely to produce clammy bread. Gluten is not abundant, but very elastic and good; nice bloom, texture and bread yield good. Usually used for smalls and paste. Suitable for either sponge or dough, but preferably the latter.

Californian Flours are weak, but dry and of good colour. Gluten very deficient, therefore yield poor. Suitable for doughing only.

Spring American Baker's Flour, criticised on the presumption of being an average grade of an average harvest year, must be decidedly termed as

being very strong and harsh. Gluten abundant, but not good, therefore texture in loaf poor. Water-absorbing capacity very high, colour and flavour inferior, dry and chippy to eat, crust foxy, a good sponging flour, and improves on being well wrought.

Winter American Baker's Flour is almost diametrically opposite to the foregoing.—Moist and weak, gluten low, therefore yield poor, flavour better than the spring grade and fairly good, considering the low class of the flour, bulk and bloom poor, a doughing flour. The higher grades are largely used for biscuits and cakes.

1 barrel of American or Canadian flour contains		196 lbs.	net.
1 sack	„	280	„
½ sack or boll	„	140	„
A peck of flour		14 lbs.	7 ozs.
A bushel	„	57 „	12 „

The adulterants of flour are rice flour, Indian corn, potatoes, sulphate of lime, and alum.

It appears that the chief offender in the States is the organisation known as the Glucose Sugar Refining Company or the Glucose Trust. In their circular they inform millers that they can realise from 7½d. to 15d. per barrel more by the aid of maize flour than without it, and the circulars they furnish gratuitously state that it is used very extensively, inasmuch as all flours are judged by their colours. This mixture, which is sold to the miller under the name of *flourine*, is whiter than wheat flour, containing a much larger quantity of starch and relatively less gluten, whereas on the London market the first qualities of flour are somewhat high in colour—almost as high, indeed, as the low grades, but for a very different reason. Low-grade flour owes its colour to the presence of the finer particles of the inner envelope of the grain; high-grade owes its to the gluten, which is relatively smaller in quantity in the whitest flours on the market. The more maize flour is employed the less wheat flour is required, and especially English wheat. When reduced to 10 per cent. the presence of maize is difficult to detect.

A good microscope magnifying 3,000 or 4,000 times is best for detecting adulteration of wheat-flour with maize flour, the starch grains from maize being easily recognised by their angular form, whereas the starch grains from wheat are of oval form.

It will always pay the retailer well to pass his flour once or twice through a fine sieve same day as sent out. This improves the appearance of both flour and bread, and few housewives will take the trouble to sift it for themselves.

The quantity of bread produced from a sack of flour varies, of course, among many other conditions, according to quality; likewise does the weight of a gallon of water vary according to its temperature. The following weights and measures are, however, in accordance with imperial and other generally accepted definitions, but are not presumed to take account of the variations experienced in practice:—

1 sack of flour	=	1 sack of bread.
or 5 bushels „		„ 6 bushels „
„ 20 pecks „		„ 24 pecks „
„ 20 stone „		„ 24 stone „
„ 40 gallons „		„ 48 gallons „

1 gallon of flour		„ 7 lbs.
1 „ bread		„ 8 lbs.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

Flourine.—A name in the United States for maize flour.

Flowers, Bouquets, Nosegays.—The trade in flowering plants and cut flowers is now very large in all civilised countries, and especially so in those districts where the climatic or atmospheric surroundings are unfavourable for their production in the open air. Indeed, they have recently come into great demand, not only by the "upper ten," but also the middle and artisan classes. Every year the number of flower lovers is increasing. In great cities like London, Liverpool, Manches-

ter, as well as in the gloomier manufacturing towns and seaports, a considerable business is carried on in flowers for house and table decoration, personal adornment, church ornamentation, memorial wreaths, crosses, etc., and hence a great industry has established itself on which thousands of families depend for the necessaries of life.

The cut-flower business particularly has been very largely developed since the introduction of the "Parcels Post." The Scilly Islands grow and export immense quantities. The Scillonian flowers leave the Isles daily about 9 p.m. during the spring season, and reach Devonport in time for the afternoon express train for London on the following day, and each cargo usually amounts to 1,000 or 2,000 boxes of bloom. Year by year the supply of spring flowers to the Scottish markets increases. The canny Scot naturally prefers those of his own country when they can be had. A dozen years ago the cut-flowers for Scotland went exclusively from the South of England and the Scilly Islands. Now nearly all are grown in Lanarkshire, Renfrewshire, Stirlingshire, and Perthshire.

Immense quantities are imported into England from the more Southern European countries. In France flower culture is one of the most paying forms of agriculture in its widest sense, especially on the Riviera, enormous quantities being grown for export as well as for the perfumery factories at Grasse. In Nice, Sospel, Lucerne, Lantosque, and other districts in the Alpes Maritimes, violets, jonquils, roses, orange blossoms, lavender, jasmine, and several other kinds are dispatched to all parts of Europe. At least 400 tons of cut flowers, valued at over £120,000, are sent away every winter from Nice, Cannes, Beaulieu, and Mentone, besides those kept for the perfumery factories; and these latter use about 100 tons of Parma violets, 15 tons of mignonette, 1,500 tons of orange flowers, 1,500 tons of roses, 250 tons of jasmine, 50 tons of tube roses, 20 tons jonquils, 30 tons of cassia, 500 tons geraniums, and 1,000 tons of peppermint, besides lavender, rosemary, thyme, and wormwood.

The bitter orange tree, *Citrus Bigardia*, receives special attention, and is extensively cultivated for making orange-flower water, while the *Citrus aurantium* is mainly grown for its flowers, which are commonly sold at about 4d. per lb., a considerable quantity of these blossoms coming to England.

In this country the most saleable flowers are carnations, pyrethrums, gladiolas, schizostylis, peonies, crocus, snowdrops, scillas, narcissus, tulips, roses, various lilies, lily of the valley, Solomon's seal, and the best varieties of Michaelmas daisies. Holland sends away annually bulbs and flowers to the value of about £150,000, and it is said one grower near London lays out £20,000 yearly in bulbs for producing flowers for sale.

Closely allied with the foregoing is the business of preparing materials for, and the manufacture of, dried bouquets, wreaths, etc. This includes the bleaching, dyeing, and drying of certain nuts, fruit carpels, ears of corn, palm leaves, fern-fronds, flowers, grasses, reeds, rushes, mosses, etc. Immortelles, or "Everlasting" flowers—a species of *Gnaphalium* and *Elichrysum*—which from their durability are made into garlands, wreaths, crosses, and other devices, to decorate the graves and tombs of deceased relatives and friends in winter.

Hitherto these decorative objects have mostly been made in Germany, but many of our florists and fruiterers have now acquired sufficient knowledge of the art to supply them, and the demand is increasing.

Those mostly interested in such matters should procure an excellent little manual on this subject entitled "*Das Trochnen und Farben Natürlicher Blumen Gräser, etc.*," by H. Hein, recently published by B. F. Voigt, Weimar.

Artificial colouring of real flowers.—There are tricks in all trades, and artificial tints are occasionally given to

freshly-cut flowers by steeping the stems in solutions of aniline and similar dyes which mount the stem by capillary attraction, and are oxidised on contact with the air. The flower preserves its odour, and the colour is inoffensive, but the parts exposed to the air are effectually tinted.

Aniline scarlet dissolved in water to about the transparency of claret has a very rapid action on flowers, colouring them pink and scarlet. Indigo carmine produces beautiful blue tints. The two combined dye various shades of purple, with curious mottled effects, some parts of the flowers becoming pink and other parts blue and purple. Greens are produced by using the blue dye with yellow. Indigo and cochineal are not very satisfactory. Amongst some of the effects produced are the following. Lily of the valley flowers become beautifully tinged with pink or blue in six hours; narcissi are changed from pure white to deep scarlet in twelve hours, and delicate shades of pink are imparted to them in a very short time. Yellow daffodils are beautifully striped with dark scarlet in twelve hours; the edges of the corona also become deeply tinged, and the veining of the perianth becomes very strongly marked. The result is beautifully seen in white tulips, which in a few hours become prettily marked with pink, blue, or whatever the colour of the solution may be. So also with snowdrops, leucojums, white lilac, and many other familiar flowers.

Very singular results are obtained in the variegated leaves of the aucuba and ivy. Single leaves, with their stalks placed in aniline dye-water, began to colour in about three hours, and in twelve hours had their margins deeply coloured. Forced leaves of the Swedish turnip grown in the dark are very susceptible to colour.

Oak leaves, hawked about the streets, often owe their beautiful autumn tints to a liberal use of rose aniline.

To preserve cut flowers a week or two put a little salt-petre or carbonate of soda in the water.

Bouquets garnis (F.) are bunches of sweet herbs. Thyme, parsley, marjoram, chives, and bay-leaf are the most common combinations.

Potting-soil.—A good business is done by plant-sellers in Paris in retailing potting-soil in baskets of about half a bushel.

Fly Papers. — F. *Papier tue-mouches*; G. *Fliegen papier*; Sp. *Papel para matar las moscas.*

Most of the old-fashioned blotting-paper articles contain arsenic, a deadly poison, and, being very dangerous, they can only be sold now by Registered chemists, and every sale must be recorded in the poison register.

(1) In making them, the paper is simply soaked well in a solution of arsenic and salts of tartar. The paper thus absorbs the poison in a moist form and is afterwards carefully dried. They should never be used in shops where foods are exposed.

(2) *Non - poisonous.* — One part of ground pepper and one of brown sugar are mixed with 15 parts of milk, and exposed on plates with or without bibulous paper.

(3) *Sticky Fly - papers.* — Size the paper with a flour paste made thus: Mix thoroughly 1lb. wheat-flour with 1 gallon cold water, bring to a boil; size the sheets of paper well, hang sheet over line, pin at lower corners and let dry; cut the sheets to 18 by 24. Melt together 1lb. white resin and 8 ozs. castor or linseed oil over a slow fire; paint each sheet as thin as possible with a short-bristle brush. In a very warm season use a little more resin; when cooler, more oil.

(4) Prepare a strong decoction, or better still, a tincture, of quassia raspings, and add to it a warm mixture of 300 parts Venice turpentine, 150 parts of poppy seed-oil, and 60 parts of honey. This preparation should be spread thickly on strong paper.

Here are five more mixtures:—

	(1)	(2)	(3)	(4)	(5)
Resin parts	55	50	65	60	50
Linseed Oil	35	30			
Castor Oil			35	30	34
Honey	10	20		10	
Glycerine					16
	100	100	100	100	100

Melt together and paint on paper while warm. The addition of a strong decoction of pepper or quassia chips to the honey kills the flies quicker.

Pieces of twine soaked in any of the above mixtures are often hung up, and, of course, the same string may be used several times.

Other remedies.—Flies object to the odour of the sweet pea, and this plant might, with advantage, be used in keeping shops, etc., comparatively free from insects. Bruised bay leaves are also very effective, so is laurel oil; but the castor-oil plant is perhaps the most powerful insecticide, all kinds of insects seem to detest and avoid it.

Paraffin oil is another simple and handy deterrent. Soak a sponge or piece of rag in the oil and rub the wood work, gas brackets, window frames, lintels, etc.

Foam or Heading for Beers, etc.—There are several of these artificial syrupy preparations and powders made for producing a white creamy foam, froth, or heading on beers, aerated beverages, etc. Each manufacturer has his own fancy name for them, such as *Foam Syrup, Foam Syrup Powder, Foam Sugar Syrup, Foam Sugar, Frothine, French Cream, Heading Liquid, Quilline Froth,* etc., etc. They are mostly made of gum, alum, etc., and are professedly helpful in retaining the carbonic acid gas in the beverages. They are often made from seaweed. Quillaia bark has long been used, but, containing saponin, it is of an irritating character. They should be readily soluble, produce a light and lasting foam, impart no bitter taste to the beverage, should not decompose nor cause fermentation, ropiness, etc.

The froth produced should be creamy white, close and solid, and free from large bubbles. One pound, costing 2/- or 2/6, is said to be enough for 500 gallons of beer or other liquid.

(1) Perhaps the most innocent, pleasant, and effective heading is a mixture of pure ammonio citrate of iron and salt of tartar in equal parts. A few grains are sufficient for a quart.

(2) To make beer retain its froth or head equal parts of alum and sulphate of iron are mixed. Some also add a little salt.

(3) Another preparation is, to each gallon of prepared syrup add from 2 to 4 ozs. of gum arabic dissolved in its own weight in water.

(4) A tincture is also made from 4 ozs. each of crushed Quillaia bark, alcohol, and glycerine, and 8 ozs. of water. This is exhausted to one pint by percolation.

From 2 to 5 drachms of this tincture to every gallon of syrup will be found sufficient to give every glass of soda water a creamy appearance universally liked. At the same time it has the advantage of being cheap, and is used in such minute quantities that it cannot be discovered by taste, also it is always ready for use, and will never spoil.

Fodder Cheese.—A name common in Canada for the inferior cheese made during the long winter months, from hay or stall-fed cows, in contradistinction to the "full grass" cheese, which is produced from the milk of spring and summer, when the animals graze in the rich pastures.

Foies Gras (fwag-rah).—G. *Gänseleber.*

Fatty livers of geese. *Foie Gras au Naturel* (Preserved liver), *Foie Gras Entier* (Whole liver), *Pâté de Fois Gras* (Goose liver pie), *Foie Gras Saucissons Truffés* (Truffled sausages). The whole of the above costly and fashionable French delicacies are composed of the fatty and degenerated livers of geese, cruelly and abnormally fed or crammed for the purpose in dark cellars or similar places.

The chief seat of the business is at Strasburg, now under German rule, but some are also prepared at Toulouse; and many of the cheaper and nastier imitations are made in Paris from horse flesh.

Foie gras is also made at Nerac from the liver of the musk-duck.

Many persons think that foie gras originated with the epicurean Louis XIV., but it dates back to the first French revolution, and was very popular during the Napoleonic wars.

The fattening of geese for these purposes is carried on in Strasburg very

extensively. It is chiefly in the hands of women, and is almost entirely confined to the winter season. Any working man's wife, with a few shillings to invest, can embark in it, and so tempting is the profit that the city of Strasburg may be said to be honeycombed with cellars stuffed in winter with live geese. These fatteners, or "crammers," buy geese from the farmers late in autumn, either lean or half-fattened. Sometimes the geese are fed first, for two or three weeks, with broad beans, and then for eight or ten days with maize; others feed with maize from the beginning. The birds are usually confined in very narrow coops or wooden cages in which they may move backward or forward a few inches, but not turn round. The cage has a narrow opening in front through which the bird can put its head to drink water from a vessel in which a lump of charcoal is placed. The cramming of the poor creatures is performed twice or thrice a day; it is dragged forth by the feeder, who places it firmly between her knees, opens the beak with one hand and crams the maize—previously parboiled in water and seasoned with salt—down the gullet with the other. Experts simply push the food down with the finger, but less skilful hands use a funnel with a smooth stick to expedite the descent. Sometimes balls made of potato flour and barley are used instead of or alternately with the maize. The goose is then thrust back into its living tomb to digest this unnatural gorging, and the process is repeated until the poor bird may be said to sweat fat through all the pores of its body; its cellular tissue, its intestines, its blood, nay even its very evacuations are absolutely loaded with fat; and it is asserted to be a very common practice with Strasburg goose-feeders to submit these droppings to a melting process. (It is somewhat humiliating to admit that this machine cramming system is now being practised on poultry in England, especially by "fatters" in Sussex, Surrey, and Kent.) In the last stage of fattening the crammer has to be very careful in watching the eyes of the bird, and in handling it. "La Revue de Thérapeutique" asserts that some feeders secretly mix powdered salts or sorrel in the food. This causes rapid enlargement of the bird's liver, but sometimes poisons it, and renders the pâté dangerous. Cases of apoplexy are by no means rare, even an unlucky blow or a hard squeeze will often kill it, and this is a rather serious loss, for the liver will be found filled with dark-coloured blood and almost useless. But even these livers are often minced fine, squeezed through a tammy, and mixed with goose fat to serve as a lining for the "terrine." When, however, the proper time for killing the bird has come, it is done with a knife; and the liver, swelled to an enormous size, will weigh one or two and sometimes as much as three pounds. This is very carefully removed, so that no scratch or other blemish may appear upon it, and should be of a light salmon or cream colour. Livers weighing 1½ to 2lbs. each are frequently taken from quite small geese which only weigh 6 or 7lbs. when drawn, and which may have consumed some twenty quarts of maize in the feeding. The livers are next wrapped in a wet muslin or linen cloth and sold to the packer, manufacturer, or pastrycook, who pays for them, according to size and quality, about 3/- per lb. for small livers to 6/- and 7/- per lb. for livers of over 2lbs. each. The manufacturer peels, seasons, and spices the raw liver, after which he places it in the "terrine" (tureen) along with peeled truffles and other ingredients.

The highest priced are "Foie Gras Entier," those consisting of *whole livers* of large size; while the less expensive, "Foie Gras au Naturel," may contain two or three small livers. When the contents of a terrine have been duly baked, a layer of fresh hog's lard is poured over the mass to keep it from contact with the air.

Pâtés de foie gras are only a *mixture*, and usually composed of 10 parts of goose liver, 15 of fresh lean pork, chopped very fine, 10 of fresh lard, 5 of truffles, and 2½ parts of sausage meat, and are often baked in crust to sell at prices from 10/6 to £5 each.

Other delicacies of this nature are *Saucissons* (sausages) *de Foies gras truffés*, *Pain de Foies gras*, and *Timbales de Foies gras*.

Considering that these preparations (many doctors say *diseased livers*) are sent from Strasburg for the delectation of *gourmets* in all parts of the world, it is not surprising that this industry aggregates yearly some hundreds of thousands of pounds. Nearly 200,000lbs. are exported yearly, value about £36,000, an average of say 3/6 per lb.

Leading Merchants.—J. A. Sharwood & Co., Ltd., St. George's House, London, E.C.

Fondants.—A French name (from *fondre*—to melt) for sweets which are made light, and flavoured to represent certain fruits, such as strawberries, raspberries, etc., and so as to melt readily in the mouth. In making these *Cream Fondants*, or *French Fondants*, as they are often called, because they were originally introduced from France, the sugar, with a little glucose added, is boiled to about 220° F., and when nearly cold is worked or "whipped" into a cream with a little colouring matter, blue for increasing the brilliancy of the *white* fondants, or red for producing *pink* fondants. It is then carefully remelted on a slow fire and suitably flavoured, but not boiled or heated too highly, and when of the consistency of rich cream, which was caused by the mass rapidly taking up air during the "whipping," it is run by hand or machinery into moulds made of either dry starch (see *Gelatine Goods*) or patent rubber. In one kind of machine the filling portion is stationary, while the moulds move continuously underneath to be filled. The fondants are finally dried at a moderate temperature.

Crystallised Fondants.—The crystallisation is effected as follows: Ordinary fondants are merely placed on trays and immersed in syrup of right strength and temperature. On cooling beautiful crystals of sugar form on the surface, and they are then finally dried and ready for packing.

Fondants are generally arranged artistically as to colours, and packed in single rows in fancy boxes, with a sheet of white paper between each layer to produce a pretty effect. If allowed to rub against each other the appearance is spoilt.

Fonds d'Artichauts.—See *Jerusalem Artichokes.*

Food and Drug Acts.—See end of book.

Food Preservatives.—These comprise:—Alum, salt, alcohol, spices, hops, borax, boracic acid, salicylic acid, formalin or formaldehyde, calcium bisulphide, sulphite of soda.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester. (See also *Preservatives.*)

Food Stuffs.—A collective term, comprising grains, flour, meal, meats, dairy produce, fish, tea, coffee, cocoa, fruits, sugar, spices, and similar commodities.

Foots.—The solid substances precipitated by the caustic alkali or other agent employed in refining oils, etc. The mixture gathers on the bottom, and is generally used for soap making.

The sugar which settles to the bottom of treacle and syrup casks is also called *Foots.*

Forbidden Fruit.—Also known as *Grape Fruit*, *Adam's Apples*, *Pomeloes*, etc.

These legendary names are applied to the fruit of several varieties of the *Citrus paradisi*, a smaller variety of shaddock. They are about the size of large oranges, and the outer surface being considerably indented, probably originated the idea that these must be the kind of fruit which Eve ate of in the Garden of Eden.

Pomelo or *Pummelo* is the Indian name for the fruit, which is distinguished by its esculent and medicinal qualities, and when eaten with sugar makes a fine dessert fruit. It grows in large clusters like the grape, and, owing to its mingled flavour of sugar, acid, and quinine bitterness, it is an excellent tonic, and is often preferred to the orange by those who have once acquired the taste for it. Large quantities are grown in the West Indies, in Ceylon, and in Florida. Hybrids of the orange and pomelo are

sometimes met with in the markets as *Sweet grape-fruit*, but they lack the valuable bitter quality.

Forcemeat, Forcemeat Balls, etc.—F. *Godiveau*; G. *Fleischfüllung*; Sp. *Almondigas*.

Commonly sold in tins with brown sauce.

Forcemeat, or *farced meat*, from the French *farce* (stuffing), is meat chopped fine and highly seasoned; it is either used alone or as stuffing.

Formaldehyde, Formalin, etc.—These liquids are powerful food preservatives, or antiseptics, and have lately come into extensive use. Formaldehyde itself (also known as *Formic aldehyde*) is a gaseous and very volatile liquid, first discovered by Dr. Koch, and is obtained by the slow oxidation of methyl alcohol. It is dangerously poisonous if used too freely, but ranks high as a deodorant as well as a steriliser. The ordinary commercial form is 20 per cent. aqueous solution. Two or three drops in a pint of milk keeps it fresh 3 or 4 days, and double the dose, say 1 part in 10,000, will preserve it for several weeks. Fatal effects have been known to result from swallowing 2 ozs. of a 4 per cent. solution. It has the formula HCHO, and is gaseous at ordinary temperatures. It is of a pale sea-green tint, has a specific gravity of about 1·070, acid reaction, and possesses a pungent and very characteristic odour. One part in 4,000 parts of water is recommended for moistening the paper used to cover jams, rinsing casks, etc., to prevent fermentation of contents when exposed to the air. The vapours gradually diffuse, and the liquid loses strength. The vapour is extremely irritating to eyes, nose, and throat, and care should be taken not to spill any on the hands or skin. No pain may be felt at the moment, but it afterwards becomes rough, white, and insensitive.

Being such a virulent poison, Formaldehyde is not so freely dealt with in commerce, and the solutions are found less dangerous and more convenient. These are commonly sold under various names, such as *Formaline*, *Preservaline*, *Preservative*, *Freezine*, etc. Formalin generally consists of about 40 per cent. of formaldehyde in 60 per cent. of water, but, of course, both it and the other solutions may vary considerably. The strength or percentage of the formaldehyde, therefore, rules the price.

At ordinary temperature, formalin gives off a vapour of formic aldehyde, which is somewhat irritating to the nostrils when inhaled; but all trace is removed by sprinkling a little ammonia.

For preserving vegetable products, a solution containing 1 to 2 per cent. of the formaldehyde suffices.

Fish and small animals can be preserved for an indefinite period in a 40 per cent. solution.

For jams, marmalades, etc., the paper covers merely require dipping in the solution. About 1 oz. in a gallon of brine is an efficient preservative for butter.

A common solution as sold to milkmen, etc., consists of 1 part of formaldehyde in 80 of water, and a quarter of a pint of this added to 18 gallons of milk will keep it fresh for three days at least, also without giving any smell or taste to the milk; but on drinking the milk a peculiar sensation may be noticed at the back of the mouth.

It is also largely employed in preserving clotted cream and many other foods, but many doctors say that such preservatives act disastrously upon the tissues of the stomach. Indeed, they argue that borax, boracic acid, salicylic acid, and other preservatives not only arrest fermentation or waste before the consumption of the food, but afterwards in the stomach, by preventing the proper digestion, and especially where delicate persons and young children are concerned.

After about 24 hours exposure to the vapour of a 40 per cent. solution, gelatine not only becomes insoluble in water, but loses its property of melting when heated. According to M. Gonin, formaldehyde is the ideal remedy for insect bites, applied with a camel-hair brush. The liquid is allowed to evaporate, and a second application is made. It is claimed that the relief from pain is immediate. Where the skin is broken a burning sensation is experienced, which is removed by washing in water. The application has the

effect of hardening and parchmenting the skin.

Formaldehyde mostly comes from Germany, and its price is about equal to that of methylated spirit.

Formosa Tea. — This is a very superior quality of tea, particularly the Oolongs, probably the best in the world, and free from colouring matters. It is grown in the island of Formosa, lately under Chinese rule, but now annexed to Japan, and is cured in small bamboo baskets. The present production is about 20 million pounds a year, and this is likely to be soon doubled. Most of the export goes to the United States, either direct from Formosa or through the ports of Amoy and Hong Kong.

Fothergill's Pills. — (See *Patent Medicines*).—These appear to be composed of aloes, antimony, scammony, and colocynth extract.

Fowl Dressing. — See *Poultry Business.*

Fowl Food.—See *Poultry Foods.*

Fox-berries. — A native berry exported from Canada.

Frankfort Black. — (See also "*Komo*" *Black.*)—Produced in Germany by burning the lees of wines, whence it is imported into this country, both in lumps and in powder. This black is an important ingredient in making the ink used by copperplate printers.

Frankincense.—Da. *Virog Virac;* Du. *Wiesook;* F. *Encens;* G. *Weikraut;* Port. and Sp. *Incenso;* Rus. *Ladon prostoi.* (Also known as *Olibanum, Incense, Thus,* etc. See also *Incense.*)

The name is given to several odoriferous resins which exhale a peculiar aromatic fragrance on burning, such as the resin of firs and spruce, and even the common concrete turpentine, which is scraped off the trunks of pine trees, *Pinus Australis, Pinus Palustris,* and *Pinus Tæda,* Chian turpentine and a juniper resin, obtained from the *Juniferus lycia* (which is imported from India and the Levant in solid brittle little balls). These all furnish the frankincenses of commerce, and are largely used in incense for Roman Catholic and Jewish churches, and also in the composition of plasters, salves, etc.

Frankincense when fresh is a softish yellow, opaque, tough, solid substance, with the same odour as crude American turpentine, but by keeping it becomes dry and brittle, darker in colour, and of a milder odour. (See also "*Olibanum Gum.*")

French Barley.—See *Pearl Barley.*

French Beans.—F. *Haricots Verts;* G. *Schnippelbohnen;* Port. *Freixoes verdes;* Sp. *Aluvias verdes.*

A name given to dwarf varieties of the scarlet runner, or haricots, and identified as *Phaseolus vulgaris,* gathered quite immature, the pod forming the bulk of the food stuff. It would be interesting to know how they got the appellation of "French."

They are native of India, very tender, and will not bear any frost. Usually sown April to June or July in rows twelve inches apart, and six inches from bean to bean, and are ready for pulling July to September; prices, 2/- to 3/- per bushel. Although the last growings usually grow very rapidly and bear well, it is little use sowing late in July, for the cold wet days of August often spoil them. French growths arrive April to June; prices, 6d. to 1/- per lb. For pickling or for winter use they may be preserved whole in brine. The pods should be young, tender, and fleshy, so as to be free from stringiness. They are usually packed in a cask with salt, in layers; each layer of beans should be about three inches deep, and covered by ½ inch of salt. When required for cooking they are soaked in water, and the salt washed out, after which they are cut up and boiled like fresh vegetables, or for the latter purpose they may be done in the same manner that cabbage is preserved in the cold climate of Germany under the name of *Sauerkraut.* The beans should be sliced in precisely the same manner as if they were to be immediately cooked, then placed in a tall earthen jar, alternately with layers of salt. This latter immediately attracts sufficient moisture from the cut beans to form a brine, which preserves the beans perfectly for months.

Great care, however, must be taken to keep the whole of the beans under the surface of the liquid by a weight on the top, for any that project into the air immediately decay. When required for use the necessary quantity is taken out, soaked for a short time in fresh water to extract the salt, then boiled and served in the usual manner. If properly preserved, they are so good that they may be served as fresh beans at Christmas time. Those who are acquainted with the unpleasant odour given out by the sauerkraut tubs in Germany may perhaps anticipate the same annoyance from the beans, but this does not occur, the sulphur element being absent.

In France they are often sliced up raw with other vegetables for use as salads. In cooking ordinary French beans the fresh pods should be dropped into boiling water in which a little salt and a small piece of soda have been dissolved, and then allowed to boil ten to twenty minutes, till they sink to the bottom.

To preserve their colour, they should be boiled without the lid on the saucepan. The choicest kind of French beans are the *Case-knife*, because they have no strings, and are consequently all eatable and easily prepared, needing only to be broken in two, not cut.

To convert French beans into "pickles" it is only necessary to soak in cold water so as to get out the salt. Then fill into bottles or jars and pour over them spiced vinegar, say, 1 gallon vinegar (white or pale is the most suitable), 4 ozs. white pepper-corns, 2 ozs. bruised ginger, 1 oz. chillies or Cayenne pods. Into half the vinegar place the whole of the spices, and allow to macerate 12 hours, then simmer (do not boil) gently for one hour in an enamelled pan with lid on. To be applied hot.

For *French Beans*, apply to Allen Jeeves & Sons, Seddington, Sandy, Beds.

French Blue.—A name acquired by the artificial ultramarine blue discovered and manufactured by Mons. Guimet. (See *Ultramarine.*)

French Bread.—In England this is made from best flour, and for the better kind of rolls and small fancy bread the sponge and dough are commonly wetted with milk and water, and occasionally a little butter is added.

When the rolls or small fancy loaves have lain in a quick oven about a quarter of an hour they are turned on the other side for a quarter of an hour longer. They are next taken out and chipped with a knife, which makes them look spongy and of a fine yellow, whereas rasping takes off this nice colour and renders them look less inviting.

French Butter.—Until the Franco-German war this butter was sent to England salted, but when Paris was besieged and a large quantity of fresh butter was shut out, it found its way to England. It was, however, difficult to sell until a London firm worked it up to secure uniformity of colour, and sold it as "*Brittany Butter.*" It soon became popular, and the manufacture and export of fresh butter direct from Normandy to English retailers soon replaced the salted. The land producing these are rich, old pastures, and the hay is so rich that the cows are wholly fed upon it during winter. No roots are given, so that the butter may not thereby be tainted.

Normandy mostly comes from Rennes, St. Malo, in white baskets of 28, 36, and 56lbs. each, but some of it has been found to contain margarine, and, in fact, its adulteration appears to be still carried on in spite of all the stringent laws made in France to suppress it.

From *Morlaix*, in Finistère, butter arrives in earthen jars containing 10 to 60lbs. each. It is excellent for kitchen and cooking purposes, and will keep six or eight months. This butter is first collected from the country farmers, and reaches Morlaix in large wicker baskets of about 200lbs. each, and all qualities are accepted. It is then emptied into large kneading troughs, where it is graded, washed, worked up to uniform quality, and then forced through a steam kneading mill to extract all excess of milk and water; 5 to 6 per cent. of ground sea salt and colouring (made of *roucou*, olive oil, and saffron) are added, and it is then packed in the jars, covered with white tissue paper, and salt spread over

the paper. The jar is also covered with strong canvas, and hoops of straw put round it to prevent breakage.

Brittany is generally packed in baskets of 28 or 36lbs. each.

The high prices long obtained for fresh butters exported from Isigny and Caen, Normandy, and from Rennes, in Brittany, have so often excited the curiosity and envy of British producers and consumers that the following account of the dairying, blending, and moulding system carried on about Valognes and Carenton, in North-West Normandy, cannot well fail to interest many connected with the provision trade.

It has been kindly communicated by M. C. Gurney, Esq., H.M. Consul at Cherbourg.

The room given up to dairy use on a well-appointed farm is separate from the dwelling room, to the north side of the farm buildings; windows with wire netting are arranged in view of proper ventilation—also the exclusion of cats and other undesirable animals. The door of access is well closed. The cement floor is always in spotless condition. A pair of clean wooden shoes lie close to the entrance for use in the dairy only. No one is admitted but the necessary workers, with hands carefully washed. All the utensils are washed in boiling water and rinsed in cold. The churns are rinsed with boiling water and nettles, then with boiling water alone, and lastly with cold water. A whisk hand-brush is used for the cleaning.

In the poorest farms a large cupboard is set aside for the butter-making; but the cream, in such cases, is more or less affected by the air of the living room.

In the majority of farms, say, where more than four or five cows are kept—the dairy floor is carefully washed and sprinkled with clean water. In some dairies a stream of water may be found running through the middle. The walls are lined with shelves, which are always kept scrupulously clean. No fireplace is ever to be seen in the dairy, but in cold weather the red cinders of the wood fire of the house are brought into the butter-making room in earthen-ware, cup-shaped pans, which have a side handle. These pans are placed on the floor, and are renewed as often as necessary. The temperature is maintained at 16° to 18° C., but pure air ventilation is indispensable.

The milking is done into large, handsome brass jars of a peculiar shape, lined with tin, and having a small neck. From these the milk is strained, and poured into other jars of brown earthenware, and conical in shape, having the large side upwards, one handle, and being fairly deep. These are placed on the shelves in sections. As the milk is brought in two or three times a day, the jars are filled to within an inch of the top. In summer the cream all rises in 12 hours, but in winter it takes 24-36 hours to do so—the longer the time the better the cream and the greater the quantity. Cracks on the cream show the moment for removal. This is done in one operation with a broad concave spatula of boxwood. What cream adheres to the sides of the jars is collected with a small spoon. All the vessels are then emptied, boiled, and rinsed. The skimmed milk is given to the pigs and poultry, having been mixed with bran and barley meal, or buck-wheat meal. Too much of the latter makes the lard melt too easily. Very little cheese is made in this district.

After removing the cream from the milk it is put into brown earthenware pans, shallower and of different shape to the jars for containing the milk. They have circular bottoms and two handles, also an orifice at the base which is uncorked once or twice a day to let the milk run off. These cream pans, and the milk jars, are left uncovered; the former remaining on their shelves until the morning of the day preceding market day, when the butter-making takes place. Usually this is twice a week, though occasionally it is three times, where the dairy is a large one, and situated in the neighbourhood of several market towns—within an easy day's drive.

The barrel-shaped churn in common use, worked by hand or horse power, and made by Simon Frères, of Cherbourg, is one of oak, with iron fittings, and has a very neat and solid appearance. The beater has been improved by practical testing, and gives very satisfactory results. A new pattern has been

brought out, which has a large opening to facilitate the removal of the butter and the cleaning of the inside. The device for closing is very simple and perfect; the central beater is easily taken out and replaced, and the stand is of wood, or wood and iron. A sliding tray receives the butter when the churn is emptied.

The churn having been properly rinsed as described, the cream is emptied into it from the pans to half of its capacity. The custom here is to add about 4 quarts of fresh milk to the cream in the churn. The reason for so doing is that the butter will come faster and preserve better. Some makers pour into the cream this same quantity of water, heated to the temperature of the dairy, 16° to 18° C. Milk, however, is better than the water. After three turns the air tap is uncorked for a few seconds; this is repeated two or three times, and then the churning proceeds with slow and even movement.

When the butter is made, the buttermilk, with the added milk or water, is drained off through the tap. This buttermilk is kept for the family table, and is much appreciated by the young people, as are also pancakes prepared with it.

Fresh water is poured into the churn to wash the butter, which is afterwards turned out into a yellow earthenware basin, broad and shallow in shape. The small portions adhering to the beaters are taken off with a spoon. With the later churns the butter falls on a wooden tray.

The butter is next beaten in the basin with a broad boxwood spatula, having a short handle. It is well washed in these basins, and then made up with this spatula into ½lb., 1lb., and 2lb. balls, placed on plates or cabbage leaves, and early next morning is taken to market.

In some dairies they are now using small hand blenders. But in La Manche the competition is sufficient to make greater care and cleansing necessary. If the butter is sold to the blenders the farmers prefer rather to add to the weight by not cleaning too much.

It is certain, however, that the best made butter fetches the best price; and so easily do farmers win a reputation that they are known to the agent of the blending mill, and their butter is taken at once, even without inquiry.

These agents get to know their business so thoroughly, that their knowledge of butter often enables them to select by smelling, tasting not being necessary.

We now come to the blending mills, and propose to follow the butter in its several processes through the mill.

As we have said, the whole place is kept scrupulously clean. It is lighted by electricity, and heated, when required, by hot water.

The flooring is of cement and tiles. Hot water boilers annexed to the mill do the cleaning and rinsing, and washing of cloths.

Arriving at the factory in cloth-lined hampers, as we have described, the butter is lifted in the cloth from the hamper and turned over on to glass-covered tables and flattened out. Several layers of various colours and qualities are placed over the first layer up to a certain height. The entire mass is then vertically cut into squares of a given size, by drawing upwards pieces of twine, previously placed at stated intervals across the table.

Tressels on tables, with glass tops, and resting on three small wheels with gutta-percha tyres, carry the squares of butter to the *horizontal blender*, a circular, concave, revolving table of wood, mounted on iron. The corrugated wooden roller tapers towards the centre of the table, to which it is attached, and where the buttermilk and water runs off.

A hand blender, for small dairies, to work 4½lbs. of butter, 2 feet 4 inches diameter, costs £2 3s. 6d. A hand or motor-power blender for small mills, working 22lbs. of butter at a time, 3 feet diameter, costs £7 12s.

Powerful blenders that can work 440 lbs. per hour, diameter of table 4 feet 6 inches, cost £40.

The horizontal blenders in use at Bretel Frères, Valognes, where 60 tons of butter are turned out per day, can work over 2 tons per hour, at 3 to 4 horse power; diameter of table 8 feet 8 inches, having two rollers, cost £180.

The butter is turned over automatically after each rolling. These horizontal blenders are sufficient to mix and wash soft and first-class butters. At Valognes

vertical blenders and horizontal laminators (lisseuses) are also in use.

The butter, leaving the horizontal blenders, is carried on the roller tables to the vertical blenders, which consist of a wooden screw revolving within a wooden cylinder. The butter is thrown in at the top, and comes out below at one side on to a wooden tray. From the table of the vertical blender it passes on to the rolling table, and is carried to the laminator or "lisseuse," which is practically a mangle. This machine is composed of two revolving cylinders of wood, between which the butter falls into troughs on wheels with gutta-percha tyres. The laminator is useful in dealing with hard butter, which often contains small nodules of greater density than the rest. These, remaining in the butter through the first two blenders would, by fermenting, cause marbling, and thus depreciate the value. But these rollers remove this defect.

The vertical blender is indispensable for colouring when the butter is too light, owing to drought or frost having spoiled the pasture. Again, this blender is an absolute necessity when margarine is used. It mixes better than the horizontal blender, and *completes* the extraction of buttermilk, but it would not *suffice* for the latter purpose.

Vertical blenders for small mills, working by hand-power 220lbs. of butter per hour, cost £8. Those for working 660lbs. per hour, £17 12s.

The vertical blenders in use at Valognes can work 2½ tons per hour, and cost £60 each.

From the *lisseuse* the butter goes to the moulding machines, which make the cubes of equal weight and size.

The wrapping in paper, bearing the Isigny mark, and packing in wooden boxes, each containing 20 cubes of ½ kilogramme, completes the process of the mill.

The "lisseuse" for small mills, working 220lbs. of butter per hour, costs £17. The Valognes "lisseuse," working nearly 2 tons per hour, costs £140. Several sizes are made between those two sizes mentioned here, in the three kinds of blending machines.

Butter-moulding machines are in use for hand-power—cost, £1 12s. Those worked by motor-power, turning out 300 cubes of ½ kilogramme per hour, cost £7 12s. The tables with glass tops, and having wheels, cost £5 3s. 6d. Hot water boilers, for 150 quarts, £7 3s. 6d. Trucks, with gutta-percha tyre wheels, £2 8s. The Normandy barrel churn, for hand-power, costs from £2 3s. 6d., to make 22lbs. of butter, up to £10 for the one which makes 120lbs. Motor-power churns, working 50 quarts of cream, cost £9, varying accordingly up to £24 for churn complete to work 400 quarts at a time.

If we consider the tables of imports of butter into the United Kingdom, we see that Normandy exports to England reached a maximum of £3,027,645 in 1892; then in 1893 suddenly declined, remained stationary till 1896, and fell again very considerably to £2,330,576 in 1897; while the total imports of butter into the United Kingdom from abroad advanced annually at a steady rate, Danish, Dutch, and colonial butter making great headway. The table of exports from the Cherbourg district shows a falling-off at St. Malo, but on the other hand an appreciable increase in the export of butter *viâ* Cherbourg to Southampton. The increase of export *viâ* Cherbourg is due to the fact that butter from the department of Calvados now reaches England *viâ* Cherbourg, instead of going direct from Caen, for the following simple reason: A few years ago there was some adulteration of butter with margarine in Calvados. One or two prosecutions were instituted and convictions obtained; whereat British importers took alarm, and sought supplies elsewhere. As a result of the prosecutions, the adulteration of Calvados butter, which had to all appearances never assumed great proportions, practically ceased, and has now been made impossible by the stringent provisions of the Act of 1897. But the butter no longer obtained a market in England. The blenders at Carentan and at Valognes, in the department of La Manche, profited thereby; and the Calvados butter, excellent in quality, found its way to

these mills, and thence, after mixing with various grades of Manche butter, inferior Brittany, and sometimes even with cheap imported butters from Italy, in severe winters, reached England in a round-about way. The opinion of a well-known blender is that the output of butter in Western Normandy has attained its maximum point. No antiseptic, not even salt, is added to the butter. Made over-night by the farmers, collected in the morning, despatched at noon to Valognes, worked into shape during the afternoon, kept in cold storage cellars as soon as packed in hampers, or in boxes of twelve 2lb. rolls, despatched by rail to Cherbourg, often the same night, the butter reaches Southampton at seven the following morning, and arrives at the London market in prime condition that afternoon. Thus it is easy to understand that best Normandy selected butter will die hard in our markets.

It has been said that the adulteration of French butter in the past has been the cause of the decline of the export to the United Kingdom by the ports of East Normandy; but this does not appear to be correct. The reason of the decrease in the export by Caen and Honfleur is due to the fact that more goes by Cherbourg, for the rich blenders of the Cherbourg district have driven out nearly all the small exporters of East Normandy, who used to send their goods by Caen and Honfleur. The great exporters of Manche do business on an enormous scale, buying their butters all over France, so that they are able to pay high prices for the splendid butters of Normandy, and are, in fact, obliged to get them at any cost in order to make saleable the inferior qualities bought elsewhere. The small exporter naturally deals only in the local markets, and he is being driven out, the butter which he exported going to swell the exports of the "best Isigny" by Cherbourg. The very best French butter, from the Isigny district, for instance, never comes to England, as the prices here never reach those of Paris. If any decline in the French butter trade with this country has taken place, it is due to the enormous increase in the quantities sent to the London market from other foreign countries and the British colonies. These have reduced prices so greatly that the inducement to French producers to send their butter here is less.

The export trade is mainly in the hands of Bretel Frères, of Valognes, and Messrs. Lepelletier of Carenton.

French Chalk.—See *Soapstone*.

French Coffee.—The chief reasons for the superiority of coffee as made in France are that more real coffee is used. The berries are roasted slowly, but much higher, almost charred, and ground much finer, both operations being done at home, and only as the beverage is required. It has long had a good reputation, which has tempted many English manufacturers to produce disgraceful imitations. The French coffees, as prepared in England, are (many of them) made up of about three parts of ground chicory to one of ground coffee, with a liberal addition of burnt sugar colouring. Of course, the worse the mixture the greater the profit to the packers, if it *can be sold*. The liquid possesses any depth of *colour*, but they have become more notorious than popular, and when liquored they are utterly incomparable with coffee ordinarily served in France. Indeed, many of them are made up of the vilest rubbish, and retailers who have any respect for their customers should be wary in purchasing such mixtures, which are neither "French" nor "Coffee." Some of the coffee made in France even must be very injurious to health. In 1891 a factory there was seized, and it was discovered coffee was being made out of a mixture of 1 part sulphate of iron, 30 parts of chicory, and 70 parts of flour.

In Southern France roasted acorns, of various species of *Quercus*, are used by the peasants instead of coffee.

For the finer qualities of real French coffee try either of the following firms:—Cave, Johnson & Co., White Hart Court, Alderman's Walk, Bishopsgate, London (established 1879)—proprietors of the Celebrated "*Comme-il-Faut*" brand of French Coffee, in ¼lb., ½lb., and 1lb. tins at 10d., 1/-, and 1/4 per lb.

Or the

sold wholesale by John Cassell & Co., 80 Fenchurch Street, London, E.C.

Speaking of the above Café Exquisite de Paris, "The Grocer" says: "It is a high-class Coffee of delicate flavour and aroma. The canister is decorated in excellent taste."

French Mustards. — These semi-liquid condiments are usually prepared from the ground black or brown seed (husks included) by the manufacturers and bottled *ready mixed*—not with water, as in England, but with salt, olive oil, vinegar, verjuice or wine must, in which various flavouring materials have been macerated, such as garlic, tarragon, thyme, parsley, mace, and other spices, and sometimes sugar and ketchup are added. Each manufacturer is supposed to have his own secret recipe.

The flavours are, of course, more like a mixed pickle or sauce than confined to that of mustard, hence they have a stale taste, and always lack the pungency of the English article. Dijon is famous for mustard manufacture, and there is more made there than anywhere else in France.

The peculiar characteristics of Dijon mustards are whiteness of colour, a certain roughness and piquancy not found in any other mustard.

The seed grown in that region is always sown on clear charcoal beds in the neighbouring forests, spaces difficult to utilise in any other way, as the young plants of green peas, potatoes, French beans, and the like would inevitably be devoured by the rabbits, wild boars, and other animals, which will on no account touch the mustard-plant. The soil gives one peculiar flavour to the mustard; another is differently to be accounted for. The mustard when in powder is commonly mixed with verjuice and new wine must, which lend a pleasant acidity. But, in order to obtain the exact degree of acidity, it is necessary that the grape be always in precisely the same state of unripeness, a degree more or less making all the difference.

Bordeaux mustards are mixed with oil and spices, and are favourably known.

Normandy mustard is a fine kind and highly aromatic.

In France the retailers are supplied in casks, kegs, stone jars, or small bottles ready for the table. There is a fair demand in this country for these French mustards wherever foreigners abound, but the average Englishman prefers having his mustard mixed fresh every day.

French Pears.—The pears of France are celebrated for their excellent qualities, and sell well in this country.

Cheapest and most plentiful in August.

French Plums.—See *Prunes* and *Plums*.

French Polish.—This is not quite like ordinary furniture polish. The simplest and perhaps the best consists of, say, 1½lbs. of shellac, 1 oz. of mastic, 2 ozs. of gum benzoin, dissolved in 1 gallon of methylated spirits, or (2) 10 parts of shellac and 40 parts of methylated spirits, and (3) a solution of shellac only makes an excellent polish. The furniture should be polished once daily for about a week with a pad of flannel or cotton wool, taking care to rub the article with sandpaper previous to each of the first four coats of polish, or the latter will not adhere well. Lastly, use a clean rubber with a little strong spirit only to remove cloudiness or any traces of oil. In most of the common kinds naphtha is used instead of spirits.

French Wines.—France was long the vineyard of the earth. Wine was made in about eighty of her departments, and only six (Côtes du Nord, Creuse, Finisterre, La Manche, L'Orne, Seine Inférieure, Pas de Calais) seemed unsuited to vine culture.

Until lately the Church there was the patron of the vine, and produced the best wine-tasters and wine-cultivators. The best growths were on monastic lands, they were cultivated by monks; every abbey had its vineyard, and every *château* (castle) its speciality. The greatest outlets by sea are Bordeaux, Marseilles, Montpellier, Toulon, Cette, and Port Vendres. But by far the greatest export is from Bordeaux, and wines are probably cheaper in that city than in any other in France. In Paris the "*octroi*" or duty charged on entering the city often exceeds the price of the cheaper wine itself.

Champagnes rank first among French wines, and are produced in the departments of the Ardennes, the Marne, the Aube and the Haute Marne; Rheims, Epernay, Vitry, St. Menehould, and Châlons being the principal centres, four-fifths in value being produced in the district of Rheims and Epernay alone. Burgundy ranks next as a wine district. It is about sixty leagues long by thirty wide, and comprises the renowned Côte d'Or, surrounding Dijon, Beaune, Pomard, Chatillon, and Semur, the department of Saone and Loire, also the department of Yonne. Altogether about 220,000 acres are devoted to vine culture in Burgundy. In the South of France, on the Rhone, the wines of Valence, Montélimar, have long been celebrated, also the arrondissements of Die and Nyons. Some of them rank with the best red and white kinds of France; such are Hermitage, Crose or Cotillon, Chanos-Curson, Mercurol, Brézême, Condrieu, Vienne, Côtie Rôtie, Villefranche, Isère, Vaucluse, etc., etc.

The Claret country is marked by the Rivers Dordogne, Garonne, and Gironde in the South-west, and in quantity this wine exceeds all others. It is also the purest that is exported from France, for the vines, being more scientifically reared and elaborately tended than in any other part of the world, there is no need to fortify the product with the spirit known as "*Dutch Courage.*"

In France the vines are grown in rows about a yard apart, and the main trunks are supported by pine or chestnut-wood props.

The "Vendanges," or gathering of grapes in France, is in September or October. Women and children cut them carefully, picking off from each bunch any green or over-ripe fruit. At the end of each row stands a man who receives the grapes into a wooden basket, which is emptied for him at intervals by a boy into a small tub, wherein they are slightly crushed to save space. A cart, carrying two vats, finally collects the whole, and bears it to the pressing-house.

Here the grapes are thrown into the wine press, a simple platform surrounded by a ledge a foot deep, where men with small rakes or with their hands remove the stalks from the fruit, but when the grapes are very sweet this is sometimes omitted, as the stalks by their bitterness will serve as a corrective; the men then, after treading the fruit, cover the pulpy mass with planks, across which a beam slowly descends by means of a vertical screw, pressing the juice through a small hole in the side of the press into tubs placed to receive it.

These tubs as they are filled are emptied into vats, care being taken to fill one vat with the first pressings and another with the second, as it will be readily understood that the liquid that runs first is of more value than that which is extracted by more powerful pressing, indeed, the third or final pressing is kept apart for the labourers on the estate, who afterwards are allowed to mix it with the lees, and to pour water over it continually for their own use until its strength is exhausted.

The vats containing the two good pressings are now allowed to remain quite full a week or a fortnight (and longer in the case of the new hermetically closed vats) during which time fer-

mentation goes on, a bubbling noise testifying to its activity.

As soon as by its taste the wine is found to be sufficiently formed, it is drawn off into new casks each containing 48 gallons, and is removed to the cellars.

In the case of the White Wines, known as Graves or Sauternes, and produced from a white grape which is picked later and allowed to ferment partially on the branch, the vats are not used, and the wines go at once into the casks and into the cellar.

A cellar or *chai* in the Médoc is seldom below ground, save in exceptionally dry localities; in damp neighbourhoods it is several feet above ground.

Here, during the first year, the wines require constant watching and attention. Throughout the first month after their arrival from the pressing-house, the wooden plug, which does duty for a bung, is only lightly placed over the bung-hole, and the cask filled up every two or three days to make good the loss through evaporation. By degrees the care is relaxed, and in March the first racking or drawing into a fresh cask takes place to get rid of the sediment deposited in the old one. Two more rackings are made in the year, and two every successive year—one in spring and one in autumn—until the wine is bottled.

Common or Light Wines are usually bottled eighteen months after the vintage; the higher class growths and heavier vintages are kept three or four years.

Before bottling, the wine has to be "fined," not only to make it bright, but to ensure its permanently remaining so. The white of seven or eight eggs, or a corresponding quantity of gelatine, is thrown into each hogshead, and the wine whipped up till it froths, then left a fortnight or more to "fall bright" for bottling.

Before leaving the subject of Clarets, we will endeavour to give the outline of what is called the classification of growths—it is simply a division by order of merit.

The "first growth" numbers only four members—the Château Lafite, Château Latour, Château Margaux, and Château Haut Brion; which means that the wines grown on the four estates named are on a level with one another, and superior to all others.

The "second growth" is composed of about a dozen names, which are considered to rank together next in order, and so on to the third, fourth, and fifth growths.

After these come the "unclassed wines," which are in their turn divided into "Bourgeois," "Artisans'," "Paysans'," ("Gentry," "Artisans'," and "Peasants'" wines).

It must of course be borne in mind that although this classification is just and correct as an average estimate, there is no year in which it can be said that all the wines produced fall exactly into the position assigned to them; for instance, the "Château Margaux," which is a first growth, will often be surpassed in value by wines classed as fourth or fifth growths, by reason of certain conditions of the weather which have been more favourable to the latter, and likewise years in which fine wines are developed to the highest perfection are often bad for the success of the coarser vintages.

The following table shows the classification of the second, third, fourth, and fifth growths or *crûs*.

SECOND.	
Mouton.	Brane-Cantenac.
Rauzan.	Pichon-Longueville.
Léoville.	
Durfort.	Ducru.
Lascombes.	Cos-d'Estournel.
Gruaud-Larose.	Montrose.
THIRD.	
Kirwan.	Brown Cantenac.
Chateau-d'Issan.	Palmer.
Lagrange.	La Lagune.
Langoa.	Desmirail.
Giscours.	Calon-Ségur.
Malescot St. Exupéry.	Ferrière.
	Becker.
FOURTH.	
Saint-Pierre.	La Tour-Carnet.
Branaire-du-Luc.	Rochet.
Talbot.	Ch.-Beychevelle.
Duhart-Milon.	Le Prieuré.
Pouget.	Mis. de Therme.

FIFTH.

Pontet-Canet.	Le Tertre.
Batailley.	Haut-Bages.
Grand-Puy.	Pédesclaux.
Ducasse-Gd.-Puy.	Belgrave.
Lynch-Bages.	Camensac.
Lynch-Moussas.	Cos-Labory.
Dauzac.	Clerc-Milon.
Mouton-d'Armaillac.	Croizet-Bages.
	Cantemerle.

Altogether, France has long been called one vast vine garden, and wine is the national beverage, but there is most drunk per head of the population in Nice than in any other town in the country. Most of the noted French wines will be found described under their respective names, but the total number is immense. Whether or not she will retain her prestige for wines in quantity or quality is doubtful. The present annual wine yield of France now only averages about 30 million hectolitres, of 22 gallons each.

In 1893	it was	50,070,000 hectos.
In 1894	it was	39,053,000 hectos.
In 1895	it was	26,688,000 hectos.
In 1896	it was	44,656,000 hectos.

And a large portion of above was manufactured from foreign growths. It is said some 50 million gallons are made yearly from dried raisins and currant pulp, also from sugar (Vin de sucre).

The vines are liable to a disease known as the *oïdium*, best combated by blowing sulphur upon the vines with specially-devised bellows before and after the blossoming and especially when great heat follows much rain. Worse than this is the small insect, *Phylloxera vastatrix*, which has worked great havoc in the vineyards. It punctures and wounds the roots and young shoots of the vine that they cannot supply sufficient nourishment to the plant.

France has also been suffering for some years from cold seasons, especially from changes of temperature during the spring, and several of the noted wines and fruits are no longer produced in their wonted quality and profusion.

In the days of Philippe Auguste (13th century) the wines of Etampes and Beauvais were favourite beverages at Court. Henry IV. (a pronounced *bon vivant*) was especially fond of Suresnes wine.

There is now not a vineyard of importance north of Paris, and as for the *petit vin* now made at Suresnes, it has become only the drink of the poorer classes. In the 16th century Macon was celebrated for its muscat wines, but the grape can scarcely be made to grow there now. Ancient chroniclers mention the vines of Northern Brittany, where now even apples are scarce. It is the same with other fruits. Languedoc no longer grows the lemon nor Roussillon the orange; even the poplar tree, so familiar in old French engravings, is nowhere to be found.

The yield of wines in France in 1898 was 710,211,898 gallons, being less than 1897 by 1,503,986 gallons. The Herault product realised about 9d. per gallon; Gironde (Bordeaux), about 1/6 per gallon; Champagne country, about 2/11 per gallon. The wine made from dried raisins, currants, etc., only amounted to 2,835,470 gallons, as compared with 9,931,284 gallons in 1897.

Besides, many of the so-called Light French wines now sold to England from France are really of Roumanian origin. It is much the same with others. Algeria produces some four million, Corsica about a quarter of a million, and Tunis 100,000 hectolitres of wine yearly, and most of these growths go into France for manufacture and export as "French Wines." British merchants are finding these things out and buying direct.

Fresh Fruit.—See *Green Fruit*.

Fresh Herrings are those newly taken from the sea, quickly marketed and consumed. They should never be washed in fresh water. The Manx are considered the most excellent. Herrings are mostly taken in large drift nets, often half a mile long and reaching down some 30 feet into the water. They are generally set in the evening, and the mesh being of a size that the fish, in trying to get through, is caught tightly by the gills, and dies the moment it is lifted out of the water. (See *Herrings*.)

The lowest quality of herrings, namely, those caught after they have spawned, are called *spent fish* or *shotten fish*.

Fresh herrings—those preserved fresh without curing—are also packed in tall tins, which are retailed at about 4d. each.

Friars' Balsam. — A compound tincture of benzoin of the *British Pharmacopœia*, composed of benzoin, storax, balsam of tolu, aloes, and rectified spirit.

Seldom used internally, but as an external application in wounds and ulcers. It is very popular among the working classes, and is also used in making court plaster.

Fricassee or **Fricandeau** (of Mutton, Fowl, Rabbit, etc.).—Port. *Ensopada;* Sp. *Guisado.*

A stew or dish of food made by cutting chickens, rabbits or veal, mutton, etc., into pieces and dressing them in a frying-pan or like utensil, and mixing with lard and other accessories.

The word fricassée is generally applied to chicken, lamb, and other small things, while fricandeau is mostly confined to veal and stewed beef.

Friedrichschall Bitter Water.—A celebrated mineral water coming in bottles from Friedrichschall, near Coburg, Germany, and containing largely soda and magnesia.

This water is much valued by the faculty as an aperient and diuretic. It is taken warm in small doses—seldom so much as half a tumbler.

A little lemon juice or wine will improve its taste.

In bottle unopened it is said to keep a long time without losing its virtues.

Frijoles (pr. freehólies).—A general name in Mexico and Central America for beans, which when cooked with pork and fat, or with dried beef, form the popular food of the people in those countries.

Frogs.—F. *Grenouilles.*

The flesh of the hind thighs of the green frog, *Rana esculenta,* is dried and eaten on the Continent and in America.

Frontignac. —A sweet French wine made at Montpellier, province of Herault, from muscatel raisins grown around Frontignac. There are two kinds, white and red, and they contain about 10 per cent. of absolute alcohol.

Epicures highly esteem this wine with certain kinds of fish.

A British wine, made in England, is also sold under the name of Frontignac.

Froth, Foam, etc. — An artificial heading for beers. (See *Foam.*)

Frozen and Refrigerated Meats. —This business may be said to have commenced in earnest in 1880 with an importation of 400 carcases until last year (1899) we imported, of sheep and lambs only, a total of 6,869,419 carcases from New Zealand, Australia, and Argentina. Large consignments of frozen meats also come from America, usually of excellent quality, though of a dull, blue colour, and much of it is doubtless thawed and trimmed, and sold as *home-grown* meat.

Canada seems to have found it unprofitable to ship live mutton to England; her formerly large exports having dwindled to comparative insignificance. The United States also has failed to see money in the business; but Argentina and the Falklands now send large consignments.

The largest frozen meat factory in the world is at Barracas, suburb of Buenos Ayres, and belongs to the Sansinena family. It is capable of an output of 3,500 sheep per day, or 100,000 mutton carcases per month.

The refrigerating methods adopted for the treatment and preservation of perishable food stuffs have already been noticed. (See p. 83.) They have developed so wonderfully within the last few years as to suggest endless possibilities. What our ancestors deemed impossibilities have become to us matters of everyday simplicity, and articles of food which they regarded as luxuries, only to be had at certain seasons of the year, are now, owing to these refrigerative processes, almost everyday articles of diet. The primary function of all refrigerating machinery is to extract and transfer heat; the primary function of cold storage is to conserve and maintain the duty performed by that machinery. A perfect cold store, therefore, must be such that the units of heat extracted from the goods contained in store by the

machine must be in exact proportion to the heat units lost by such goods stored. If such were possible the cost of maintaining the required temperatures in the stores would be very small. Unfortunately such perfection is impossible, but by proper methods of construction and the application of suitable materials, a somewhat near approach to this goal has been attained. Vegetable silica seems to be the most useful material for the prevention of the transit of heat. Buildings for use by the general public are now substantially erected and proper facilities given for receiving and delivering the goods to be stored. Ordinary building materials are used for the shell and main structure of the buildings, care being taken to insulate the main columns and supports from earth contact, so as to avoid transit of heat into the building, but it has been found best to use a non-absorbent material for the inner lining of cold storage chambers, as well as floors and ceilings. The material that lends itself best to take the place of timber is expanded metal filled in with an inch and a half of cement plaster, on to which opalite is laid in cement. The whole becomes a solid permanent wall impervious to moisture or germs, and capable of being washed out periodically, and provides a sanitary and proper chamber for the preservation of perishable food.

American killed carcases may be known through being bruised about the legs, by which they are hoisted before being killed. The fat also of all frozen meat is generally deficient, and is apt to be more or less coloured with red serum. Through defective arrangements in transit, perfectly sound meat may arrive covered with blue mould; or by careless storing on arrival, the surface may get moist and tainted, while the carcase remains sound. On the other hand, frozen meat which looks very well on the surface may be a little "gone" near the bone in the centre.

Hence no examination is quite satisfactory unless the carcase or piece be cut through.

Most of the larger "Stores" and many individual grocers in the manufacturing districts are taking up the distribution of these meats, especially mutton, lamb, and salmon. The trade is easily conducted, and the profits are good. The expert trade knowledge required is so trifling that any intelligent business man can acquire all that is necessary in a few days, and any able-bodied youth of eighteen years or over can master the technicalities of cutting up the carcases; there is no dirt and little or no waste. The large London providers have already proved their perspicacity by embarking in this trade with marked success, and such firms as the Army and Navy Stores, Civil Service Stores, Harrod's, John Rose & Co., and Whiteley's, etc., are all doing a large and increasing business, especially in New Zealand Canterbury mutton and lambs. Many a grocer with the space to spare might do worse than to give the matter thought and consideration.

Frozen Milk has become an important article of trade in European centres. The milk is frozen in different sized "bricks," and in this way it is claimed its purity and freshness are insured. In Paris it is sold in cans, will keep good quite a month, and is very conveniently carried about.

Fruit. — See also *Canned Fruits*, *Dried Fruits*, *Green Fruits*, *Prunes*, etc.).—The consumption of fruit, both fresh, dried, cooked, and preserved, is increasing rapidly every year, especially in the larger towns and cities. The reader will find nearly every kind referred to under its proper heading. Although far from agreeing with extreme vegetarianism, there is no doubt that the more liberal use of fruit is highly commendable. It is not only agreeable to the taste and beneficial to the system, but the juice which all fruits contain has a direct tendency to dissipate the craving for malt and spirituous liquors. Persons accustomed to beer drinking will generally find a juicy apple to afford more refreshment, and same time to neutralise the desire for alcohol. It seems rather a pity that temperance advocates do not make more use of this fact in their controversies.

Apples supply the higher nerve and muscle food, but do not give stamina.

Prunes afford the highest nerve or brain food, supply heat and waste, but are not muscle feeding; they should be avoided by those who suffer from the liver. Oranges are refreshing and feeding, but are not good if the liver is out of order. Green figs are excellent food. Dried figs contain nerve and muscle food, heat and waste, but are bad for the liver. The great majority of small, fresh, seed fruits are laxative. All stone fruits are considered to be injurious to those who suffer from the liver, and should be used cautiously. Lemons and tomatoes should not be used daily in cold weather; they have a thinning and cooling effect. Raisins are stimulating in proportion to their quality.

Fruit Crystals for *Summer Drinks*.—There are now several makes of these popular powders or "crystals." They were first invented and introduced by De Carle & Son, Norwich, and that firm seems still to possess the secret of making the finest quality. They send out enormous quantities, and probably obtain the highest prices.

As a general basis cheap makes consist of about 29 parts of sugar in small crystals and 1 part of tartaric acid in the same form. A portion of the sugar is first rubbed down with sufficient concentrated essence of the desired flavour, and the whole suitably coloured.

Thus, to make Lemon Crystals, take 29 ozs. sugar, 1 oz. citric acid, essential oil of lemon 30 minims, and, if desired, a little saffron to tint.

Pine-apple, raspberry, strawberry, and other sorts may be prepared in a similar way, care being taken to use a proper quantity of essence to give the desired flavour.

Gardner's patent "Rapid" sifter and mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Fruit Essences.—These are liquids which possess the agreeable refreshing taste and flavour of fresh fruits.

The process of their manufacture is very difficult and rarely successful, except in a few chemical laboratories, where they form a speciality and where they may generally be had of excellent quality and at very low prices.

Some kinds are also prepared artificially from chemicals. Those *guaranteed* pure and highly concentrated are the best.

The Germans now send to this country very large quantities of natural and artificial fruit juices in highly-condensed forms. Raspberry and other juices are admitted duty free into England when the spirit they contain is trifling or natural. Several of the manufacturers of grocers' sundries import these juices, and some also use the artificial fruit essences from the German chemical works.

Used in confectionery in the manufacturing of liqueurs, cordials, and summer drinks, also in perfumery.

Fruit Ices.—See *Ice Creams*.

Fruit Jellies.—(See page 52, also *Table Jellies*.)—These are sometimes prepared wholly from fruit and sugar. The fruit juices are generally mixed with about one-half their weight of refined cane-sugar, and boiled until the liquid jellifies, which is tested by dropping about half a teaspoonful on a clean cold plate, and noticing whether it sets stiff or runs off in liquid form. If the former it is sufficiently boiled, and is emptied out of the pan. When about half cold it may be filled into small earthenware or glass jars, and covered over like jam. In boiling it should be skimmed two or three times, and it is best not to add the sugar until the boiling has commenced. But very pretty and economical jellies are now made from the fruit juice and gelatine, with glucose instead of sugar. In no department of preserving is there more uncertainty than in jelly manufacture, so much depends on the quality of the fruit. This is more pronounced in the case of small fruits than with the larger kinds. When currants are over-ripe, or have been picked after a rain, the result of using them will be doubtful. Pectine, which forms the basis of vegetable jellies, is a substance which, in its composition, resembles starch or gum. It

gives to the juices of the fruits the property of gelatinising. This property is at its best when the fruit is just ripe—better a little under than over ripe. When boiled too long it loses its gelatinous property, and becomes of a gummy nature. No jellies should be boiled over 20 minutes.

Apply to De Carle & Son, Fruit Drink Works, Norwich.

Fruit Juices.—(See also *Cordials.*)—This liquid form of preserves is most useful, convenient, and wholesome. The juices of the strawberry, raspberry, peach, apricot, grape, etc., are only boiled for about 10 minutes, and sealed while boiling hot. They may be thus canned with or without sugar, and are very handy for creams, ices, drinks, etc.

The following methods are also commonly adopted:—

Strawberry Juice—(1.) Cover strawberries in a wide glass with fine sugar, draw off the fluid and strain. Then boil the juice with the addition of 1 gm. salicylic acid, dissolved in cognac, for each kilo. Mix the syrup with a little rum, or arrack, and store in small bottles.

Natural Strawberry Essence. — Ripe fresh berries are pulped, macerated with the equal weight of alcohol for fourteen days, pressed slightly and filtered.

Artificial Strawberry Essence. — Natural strawberry 2·5 kilos, amylacetate 500 gm., raspberry wine 1 kilo, cherry laurel oil 2 drops, rose oil 1 drop, sugar 40 kilos, water 60 litres, alcohol 25 litres, and a little vegetable colouring matter.

Essence of Lemon.—(1.) Macerate the fresh peel of forty lemons and thirty oranges with alcohol 8 litres and water 2 litres, for two or three days; then distill off 8 litres. Dissolve in every 100 gm. of this distillate citric acid 75 gm., and add water 200 gm.; colour with a trace of orange, and filter after shaking with talcam; mix 100 gm. of the filtrate with simple syrup, 2 kilos. (2.) Lemon oil 11·25, rose oil 0·03, are dissolved in alcohol 80 per cent. 200·00, tincture of orange peel 9, tincture of lemon 9, prepared from fresh peel, and tincture of vanilla 1·5 are added. Of this essence 3 parts are sufficient to flavour 1,000 of simple syrup. *Lemon juice* is best prepared from freshly pressed and filtered juice; 10 parts are boiled in a porcelain dish with sugar 18 parts, or citric acid, 1 to 2 parts, may be mixed in an equal volume of water, mixed with simple syrup, 100 parts, and flavoured with 1 or 2 parts of a tincture prepared from fresh lemon peel and alcohol.

Artificial Lime Juice.—Citric acid 4, tartaric acid 4, are dissolved in alcohol 12 and water 25, lemon essence 40, simple syrup 1·000 are added.

We believe that Messrs De Carle & Son, Norwich, were the first to make the fresh juices popular.

Lemon Juice for Drinks.—Sugar 100, distilled water 50, citric acid 7·5, tincture from fresh lemon peel 5 to 8, and orange-flower water 15 to 20.

Raspberry Essence. — Raspberry syrup may be used with the addition of citric acid dissolved in water and red colour. (2.) Raspberry juice 1·000, white sugar 1·600, acid tartaric 35 to 40, alcohol 30, and a little red colour. This syrup is prepared in the cold, the acid being dissolved in a little warm water.

Special Manufacturers.—De Carle & Son, Norwich, original makers and inventors, to whom apply for prices and particulars.

Fruit Salts.—Different makers may vary a little in their proportions of the ingredients, but the following are good average recipes:—(1.) 2lbs. icing sugar and ½lb. of each of the following: Epsom salts, carb. soda, cream of tartar, tartaric acid, and citrate of magnesia all well mixed together. One compound is absurdly advertised as preventing any over-acid state of the blood, but, as most people know, the blood is always alkaline and cannot become over-acid. (2.) Bi-carbonate of soda 23·49 per cent., tartaric acid 20·37 per cent., sulphate of magnesia (Anhyd) 7·44 per cent., cane sugar 42·11 per cent., moisture 6·59 per cent. equals 100.

The above-named quantity of sulphate of magnesia is equivalent to 15·2 per

ent. of Epsom salts. The mineral ingredients are usually mixed together, artially dried, and afterwards blended ith the cane sugar. This is a fair ample of saline of a similar composion to many in the market.

Fruit Syrups.—(See also *Syrup.*)—'hese are obtained and preserved ither by the cold process or by heat. 'he fullest flavour of the fruit is btained by the former. The fruit must e freshly gathered and the sugar of est quality. Then the syrup may be repared either by simply combining ie juice expressed from the fruit with ugar or the uninjured berries may be ixed with the sugar, when the latter ill extract the juice, leaving the berries rivelled and tasteless.

When prepared by steam or hot water ie syrup is scalded. The water should e distilled, and the operations should e performed with the greatest possible elerity.

They should be bottled quite hot, uickly corked, and tied over with ladder or other air-tight material. mall bottles are better than large ones iat have to be opened and re-closed so ften.

Candying or crystallisation is preented by adding a little glucose or cetic and citric acid, and fermentation y a little sulphate of potassa or of me.

Gardner's patent "Rapid" sifter and ixer freely used for above. Prices rom 50/- to £100. Catalogues from Vm. Gardner & Sons, engineers, loucester.

Fucus, or **Rock-weed** (also known s *Varec* or *Vraic*).—These are a variety f sea-weed found on rocky shores beween the tide marks. Some of them ield soda, iodine, glue, etc., and in easons of scarcity this species of vegeation is often eaten raw, both by nimals and human beings. In the 'hannel Islands large quantities are sed as manure.

Fuel. — Various kinds are described nder—

Anthracite,	Gas,
Asbestos,	Lignite (Bovey),
Block coal, or	Liquid fuel,
Briquettes,	Paris coal,
Coal,	Peat moss,
Coke,	Petroleum,
Firelighters,	Press coal.

Fullers' Earth or **Woburn Earth.**—Du. *Voläarde;* F. *Terre à Foulon;* Ger. *Wakererde;* It. *Terra da Purgatori;* Lat. *Creta fullonica;* Rus. *Schiffernaia;* Sp. *Tierra de Batan.*

A porous clay, or alluminic silicate, found in various geological positions, and in different parts of the country. Long ago it was plentifully obtained at Woburn, in Bedfordshire, and then got the name of *Woburn earth.*

It is also abundant in Bucks, Hants, Beds, and Gloucestershire.

The best is got near Reigate, Surrey, where there is a bed 10 feet thick.

It is soft and greasy to the touch, and consists of about 53 per cent. of silica, 10 per cent. of alumina, and 9 per cent. of peroxide of iron, etc. It is usually of a greenish grey colour, but sometimes bluish spotted, and separates into powder if soaked in water, making a slight hissing noise; also melts readily on the tongue, like butter.

Like other soft marls, it absorbs grease, and is principally used by fullers in taking grease out of cloth before applying the soap.

The value of the prepared article depends on the alumina present, which should be at least one-fifth of the whole, but not more than one-fourth, lest it become too tenacious.

It is sold both in lump and in powder, at from 37/- to 75/- per ton.

The best varieties, such as are suitable for toilet purposes, are of a clean drab or fawn colour; the so-called White or Precipitated Fullers' Earths which are sometimes offered are not Fullers' Earth at all; they are generally China Clay or Terra Alba, which differs from the genuine earth in both its physical characteristics and chemical constitution. The substitution is altogether unjustifiable, as China Clay lacks those peculiar healing and protec-

tive properties which make Fullers' Earth such an excellent dusting powder.

Matthews' Fullers' Earth was the first preparation brought out for toilet purposes.

An excellent quality is now prepared at Frongoch by Mr. R. J. Ll. Price, of Rhiwlas, Bala, North Wales.

Fulling Soap.—A soft soap used in cleansing and scouring woollen fabrics. It is composed of 125 parts of potash oil-soap, 54 of clay, and about 110 of calcined soda-ash. It should be free from resin, soda, and silicates, as these injure wools.

Furmenty or **Frumity.**—Prepared by steeping new wheat in water, and placing the pan in an oven, where it is seethed at a temperature of 100° to 120° F. for 18 to 36 hours, when the grain will have ruptured its skin, and at the same time the kernel will be softened and the saccharine process will have commenced. It is then braised or shaken in a bag till the outer skin is peeled off, and when winnowed or washed the wheat is ready to be boiled with milk. It is afterwards spiced and sweetened with sugar, and ready for serving hot. Furmenty is a very ancient food, and was widely popular in the middle ages. In some districts it is eaten to celebrate the harvest home and in other districts Christmas Eve, but it is only now prepared in country places and is very indigestible.

Furniture Oils.—These mixtures are prepared in various ways:—

1. Two dr. acetic acid, ½ dr. oil of lavender, 1 dr. rectified spirit, and 4 ozs. linseed oil.

2. One pint linseed oil and 2 ozs. alkanet root; heat, strain, and then add 1 oz. lac varnish.

3. One pint linseed oil, 2 ozs. rectified spirit, and 4 ozs. butter of antimony.

Furniture Cream.
Furniture Paste.
Furniture Polish.
Furniture Wax.
—These are names given to numerous preparations intended to re-polish or give a gloss to furniture that has been previously French-polished, but which has become faded or scratched.

The following are a few popular recipes:—

1. Take 5 ozs. beeswax, 3 ozs. white wax, ¾ oz. powdered white Castile soap, 1½ pints good turpentine, and 1½ pints boiling water. First melt the waxes together in a dish or pan near the fire, and while hot add one-third of the turpentine. Stir the soap into the boiling water, and when dissolved add to it the remainder of the turpentine. Finally mix all together, stir well, and then leave till cold. It may then again be well stirred, and filled into pots ready for use.

2. 1lb. beeswax, 4 ozs. soap, 2 ozs. pearlash, and 1 gallon of water; boil together, and stir until well mixed.

3. Beeswax, spirits of turpentine, and linseed oil, equal weights of each; melt and cool.

4. 1lb. beeswax, 5 ozs. linseed oil, and ½ oz. alkanet root to colour; melt, stir, and cool.

5. 4 oxs. beeswax, 10 ozs. turpentine, and a little alkanet root; melt, strain, and cool.

6. 4 ozs. beeswax, 1 oz. resin, 2 ozs. oil of turpentine, and a little Venetian red to colour; melt, stir well, and cool.

A Japanese furniture polish which is highly appreciated is made with 1 pint of linseed oil, 1 pint of strong tea, the whites of two eggs, and 2 ozs. of spirits of salts. These are well shaken each time the preparation is used. A few drops are applied with a soft linen pad, afterwards well polished off with an old silk handkerchief or a chamois leather.

Special Firms.—Day & Martin, Ltd., London and Liverpool (see advt. near end of book); E. Mitchell & Sons, 5 Burnet Place, Bradford, Yorks; J. Parkes & Co., Priory Works, Warwick; Punch Polish Co., Hick Street, Birmingham (F. Cooke, proprietor).

Fusees, or **Vesuvians.**—F. *Allumettes-tisons.*

Names given to a kind of matches or cigar lights, for lighting pipes, cigars, etc. The heads are made up mostly with, say, 18 parts saltpetre, 19 char-

coal, 7 powdered glass, and 5 or 6 parts of gum, a little scent, say of satinwood, lignum-vitæ dust, cascarilla bark, or gum benzoin, is added to emit a fragrant odour. The igniting substance is same as for safety matches. They are intended to ignite by friction, and not blow out by the wind in the open air.

Fusel Oil, or **Grain Oil** (also known as Potato Oil, Potato Spirit, Crude alcohol, Amylic alcohol, etc.).—A colourless limpid spirit of cheap, inferior quality, made out of various alcoholic substances, such as fermented potatoes, or the dregs and refuse from distillation. It has a higher boiling point and is less volatile than ordinary alcohol, hence it chiefly accumulates in the latter portion of distilled liquors. If the portion which distils between 260° and 280° F. is collected apart and redistilled the oil obtained has a fixed boiling point of about 268° F. It possesses a peculiarly irritating and burning taste, and a strong nauseous and oppressive odour, and in quantity is exceedingly injurious.

This deleterious component of alcohol is often used in the manufacture of cheap whisky and other spirits, also in certain fruit essences, such as jargonelle, pear essence, and others.

If whisky on being mixed with four times its bulk of water turns a whitish colour it is probably owing to the presence of this unwholesome fluid.

It is, however, the opinion of Dr. Lander Brunton, physician to St. Bartholomew's Hospital, that there are worse impurities in some spirits than fusel oil. In his lectures, 1897, he says that although fusel oil is an impurity, and seems to have an injurious effect in rendering the mixture of ethyl and amyl alcohol more active, causing headache, but the substances that probably have the greatest effect in exciting the maniacal fury in the drinker are the so-called *furfurane* series. Furfurane, he says, seems to have the power of acting as an anæsthetic to a greater extent than alcohol has. It lessens the irritability of the sensory part of the human system to such an extent that it abolishes voluntary movement. It has several compounds. Furfurane alcohol is highly stimulating and delightful for a time, but reaction and headache follow. The compound furfur-aldehyde, or furfur-ol, has an entirely different action, and this is the substance which arouses evil tempers and sullen mania and provokes crime.

Mr. Bannister, of Somerset House, has also testified that the fusel oil in spirits is much exaggerated. He says there is probably more of it in half a pound of pear drops than in a bottle of Scotch whisky.

G

Galangal, or **Galingale Root.**—Chin. *Liang-kiang;* Da. *Galange;* Du. *Galgel;* F., It., Sp. *Galanga;* Ger. *Galgant;* Port. *Galgangal;* Rus. *Kalgand;* Sw. *Galgant.*

The aromatic and tuberous roots of the *Maranta galanga,* or *Alpinia officinarum,* of the nature of ginger and pepper, and much used in Russia, China, Sumatra, Java, and other Eastern countries for the same purposes as ginger.

There are two sorts imported into this country, known as the greater and the lesser. They are both used as a spice. The greater is the root of the *Kempferia galanga,* a knotty root from the Dutch Indies, with several arches on the surface, of a reddish brown colour on the outside and a yellowish white within, which is very like ginger in smell, taste, and composition. The lesser galangal, from China, which is the most esteemed, is a knotty jointy root, about an inch long and about half an inch thick, with a brownish red coat and a pale red colour within. It has several circular marks, or rings, on the outside, has a hot bitterish aromatic, biting taste, like pepper, and a fragrant smell.

Galantine. — G. *Kalte gefüllte Fleischrolle.*

A French title for a dish of veal, chicken or other white meat, which has been boned, stuffed, tied tightly, and boiled with spices and vegetables. It is garnished with aspic jelly, and intended to be served cold.

Some people often confuse galantines with brawns; but, although first cousins, it should be remembered that brawns are stewed in their own gravies and liqueurs, and consist of meats and jellies mixed together, while galantines are merely fish, flesh, fowl, or vegetables pressed and *cased* in jelly.

Gallipoli Oil. — (See also *Olive Oil.*)—Olive oil shipped from a seaport town of that name in Naples. The olives are merely thrown into heaps as soon as gathered, and allowed to ferment before the oil is extracted. It is largely used in woollen manufacturing and in turkey-red dyeing.

Gallipoli is the principal port of the Mediterranean for the shipment of olive oil, being situated in that part of the country where the oil is produced in the greatest abundance. The export is from two to three thousand tons a year, and the town itself is undermined with large cisterns about 30 feet square, cut in the limestone rock, which is peculiarly well suited for storing and preserving the oil.

The bulk of it reaches Gallipoli in sheep or goat skins from Bari, Puglia, and Calabria, carried on mules, and most of it comes to England.

Galls (also known as *Nut Galls, Gall Nuts, Oak Apples,* etc.).—F. *Noix de Galle;* It. *Galles;* Per. *Mazu;* Port. *Agalhas;* Rus. *Orêkhi;* Sp. *Agallas;* Sw. *Galläple;* W. *Afalau'r derw;* G. *Gallapfel, Gallus.*

These are small hard berry or nut-like excrescences, lumps, or tumours, which grow on oak trees of different kinds in various parts of the world, particularly in the Levantine oak.

They are not a fruit, but are produced by a fly, a species of *Cynips,* or gall-wasp, which first appeared in this country about 1855, which pierces the soft twig and lays its eggs in the puncture; this causes a swelling of the bark, which grows into a perfectly round shape, and varying from the size of a pea to that of a walnut. When the larvæ are grown into gnats they eat their way out, leaving a small round hole.

Oak-galls are often improperly called "Oak apples," but the true oak apples are the spongy balls produced by *Teras terminali,* and sacred to the memory of King Charles.

Cranberry Galls are produced on the cranberry stem by a minute fungus.

Apples of Sodom (so called), which are occasionally brought as curiosities from the shores of the Dead Sea, are only large galls, full of dust and larvæ or the grubs of insects.

The best two sorts of galls known in commerce are Oriental and European. The former, also known as *Turkey galls* (*Quercus infectoria*), come from Aleppo. They are the size of a small round nutmeg, and have usually a considerable number of tubercles rising on their surface, broad at the base and terminating at a point. They are of a very solid and firm texture, hard to break, and very heavy.

Chinese or *Japanese galls* are produced by *Aphis chinensis* on *Rhus succedanea,* and are known as "Wu-pu-tze galls." They yield about 70 per cent. of tannin.

The European galls, as those of France and Italy, are rounder than those of Aleppo, of the same size, but have perfectly smooth surfaces, without any protuberances; they are very light, easily broken, and often spongy and cavernous within. They are also of a much less austere taste, and of much less value both in manufactures and medicine. The best gall nuts are green or blue, and contain 60 to 70 per cent. of tannic acid—indeed, no other natural product is so rich in tannin.

In the London market, galls are classed as blue, green, and white; the latter (being those from which the insects have emerged) are not much esteemed. They are sometimes dyed

blue, but the fraud may be easily detected by the hole left behind by the insect.

Gambier, or **Gambir,** often erroneously called "*Terra Japonica,*" is an extract or dye-stuff, like *Cutch,* and made by boiling the leaves of *Uncaria gambir,* a climbing rubiaceous shrub.

First introduced in 1807, it has become indispensable in the tanning and silk trades, and is also used in India and the Dutch settlements for chewing, as well as an astringent in medicine.

Great attention is paid to its cultivation in Singapore, Sumatra, Java, India, and other tropical countries, about £1,000,000 worth being exported annually from Singapore alone. It ranks second in importance of the products of the Malay Peninsula.

The short leafy twigs are picked by hand two or three times a year, and thrown into vats of boiling water, where they are stirred about and bruised with wooden forks for about six hours. The flaccid masses having been taken out and drained into the vat, the boiling lye—of a yellowish olive-green colour, like thin pea-soup—is then poured into shallow wooden tubs to cool. To solidify it is next stirred by thrusting a short thick cylinder of very soft mahang wood into the tub, and rubbing the fingers up and down on the surface of the cylinder. The fluid gradually thickens in about fifteen minutes, contracts, turns a paler colour, and looks like soapy cheese. When cold it is turned out as from a mould, and cut into small cubes. Four kinds of gambir are made by the Malays. *Gambir bulac* (round gambir) is the most expensive of the chewing gambirs, and consists of thin circular biscuits about 1½ inches across and a line thick. The Siak gambir of this form often contains rice dust and cloves as impurities. *Gambir papan* (board gambir) is in thin squares about 1½ inches square and one line thick. This is light brown, and crumbly in texture. *Gambir paku* (nail or finger gambir) is in sticks about 3 inches long, and very dark in colour. *Gambir dudur* (dice or cube gambir) is made in small cubes an inch each way. Other forms are manufactured for special markets, but the fancy of the natives is for the above.

Gamboge. — Da., Ger., and Rus. *Gummigutt;* Du. *Guttegom;* F. *Gommegutte;* It. *Gommagutta;* Port. *Gutta gamba;* Sp. *Gutagamba;* Sw. *Gummigutta.*

A concreted vegetable juice, or gum-resin, and is called gamboge because it originally came from Camboja, in Siam, formerly the capital of the kingdom of Cambodia. The best pipe Gamboge, from Siam, is obtained from the tree *Garcinia Hanburii,* and consists of a resin, with 15 to 20 per cent. of gum. It is brought to this country chiefly from Ceylon, in the form of obicular masses, or of cylindrical rolls of various sizes, is of a dense, compact, and firm texture, and a beautiful yellow colour.

Ceylon gamboge is obtained from *G. morella,* and that of Southern India from other species.

The finest sort is of a very deep yellow or bronze colour, breaks shiny, and is free from dross; it has no smell, and very little taste unless kept in the mouth for some time, when it impresses a slight sense of acrimony.

Gamboge is used chiefly as a pigment in water colours; but, being a powerful purgative, it is also used in making certain kinds of pills. About 88 per cent. is soluble in alcohol, and it was formerly employed in colouring confectionery, lozenges, etc., when a primrose, straw, or light yellow tint was required, but is now considered an adulterant.

Gammon.—The hindermost quarter of a side of bacon. (See *Provisions.*)

Ganja. — (See also *Bhang.*)—Ganja or Gunjah is a narcotic stimulant prepared in India from the hemp leaf. This Indian hemp-plant grows readily without cultivation in almost any part of that empire, and the smoking of ganja to excess is considered much more harmful than opium. It is, in fact, the most noxious of all intoxicants now commonly used in India. But as that

country abounds with other wild plants capable of yielding products still more deleterious in their effects than either ganja or opium, the result of prohibiting, even if it were possible, the growth and use of these latter drugs to satisfy the cravings of the poorer classes for stimulants would probably induce the use of those which are still more baneful in their effects.

Garbanzos. — The Spanish name for the chick pea, which is the grain or vetch of the *Cicer aretinum*, and largely used as an ingredient in the famous *Olla podrida*.

GARLIC.

Garble. — The dust, dross, refuse, or faulty pieces of spices, drugs, etc. *Garbling* is the picking out the worst of any commodity.

Garbled is a term applied to drugs, dyestuffs, spices, etc., when they are much broken or otherwise reduced to small imperfect pieces.

Garlic or **Churls Treacle.** —Da. *Hoidlog;* Du. *Knoflook;* F. *Ail;* Ger. *Knoblauch;* It. *Aglio;* Per. *Seer;* Port. *Alho;* Rus. *Tshesnok;* Sp. *Ajo;* Sw. *Lök;* W. *Garlleg.*

A bulbous herb, *Allium sativum*, closely allied to the onion, leek, and shalot. In fact, it has all the properties of the onion in a more intense form. This name was derived from the Anglo-Saxon *gar*, a lance (referring to the spear-shaped leaves), and *leác*, a pot herb, and hence the word *leek*. It loves mountainous countries, and is so profuse in Switzerland that even the ale tastes of it, and it infects the corn with its aroma. It also abounds in Sicily, where it grows naturally. The first year after sowing the seed only produces a single bulb or clove, but when this is replanted, the following spring, several cloves are produced from the same bulb. Each bulb is composed of six or twelve smaller ones, called *cloves* of garlic, and which are enclosed in one common envelope.

Garlic has a very acrimonious taste, strong flavour, and rank odour, which is disliked by many, but it has long been highly esteemed as a seasoning in cookery, especially in Europe; perhaps, most in Spain and least in England. It is highly relished by the Russians, Poles, and Spaniards, and especially by the Jews. It is also very popular with the French in Provence, Languedoc, and Gascony, where the country people season nearly all their food with it. In Provence the cloves are pounded and mixed with olive oil, forming the celebrated *Ailloli*. The

Roman soldiers used to be fed with garlic to excite them in battle, so were also the birds in cock-fighting days.

The Egyptians of old adored the plant, but the Greeks abhorred it.

Garlic is said to be very stimulating, creates a good appetite, helps digestion, increases the secretive and absorbent organs. It is also a good vermifuge, cures or prevents marsh-fevers, and has other medicinal properties.

It was formerly a popular specific in England for leprosy, when that disease prevailed here, and also formed one of the principal ingredients in the "Four Thieves Vinegar," said to have been so successfully employed at Marseilles for protection from the plague which once raged there. In times of cholera a few cloves of garlic, crushed and placed upon saucers here and there in dark corners where there may be impure air, have long been considered invaluable. While some mariners would almost as lief go to sea without a compass as without a plentiful supply of garlic in the "stores."

It can be advantageously used in all kinds of broths or soups, with fish, fried or boiled, with roast or grilled meat, in the same way as an onion, and for hashes and stews nothing is more flavouring.

It is still used in some countries for rubbing on the skin in cases of fever and nervous diseases of children. Garlic is most plentiful and cheapest about October, Dutch garlic then averaging about 10/- per cwt. bag.

Garlic Oil.—This product is more popular on the Continent and in America than in this country. It is largely distilled at Leipzig, and the whole town is often redolent of the odour. It is coming into use in the manufacture of pickles, piquant sauces, and other condiments, and saves a great deal of time and trouble as well as effecting economy in price.

About 30 grains of this essential oil is equivalent to some 7lbs. of fresh garlic.

Garlic Vinegar may easily be made by cleaning, peeling, and chopping up or bruising 1lb. of garlic, and soaking in 2 gallons of vinegar for two or three weeks. Then strain well through thick flannel, bottle, and cork.

Gas Tar, or Coal Tar.—See *Tar*.

Gaspereaux.—A North-American name for the ale-wife, a small kind of fish, largely exported in pickle to the Southern States and to the West Indies for the negroes. It is very dry when salted, but very good if eaten fresh.

Gauffres.—G. *Waffeln*.

The French word for "wafers," a kind of light and thin spongy biscuits.

These confections used to be home-made in nearly every French household. They are made in much the same way as *waffles*, and "marchands de gauffres" are yet to be met with in fairs, parks, and fashionable promenades, clad in white clothes and caps, baking their "gauffres" in portable stoves, and selling them well sugared and smoking hot on neat white plates. (See. *Waffles*.)

Gazogenes or Seltzogenes.—The *gazogène* is a portable apparatus for aerating waters on a small scale at home for domestic use. It generally consists of two globes, one above the other, connected by a tube, the lower containing water, and the upper the ingredients or powders for producing the aerated liquids. When water is gently introduced into the upper globe from the lower, by inclining the vessel so as to about half fill it, chemical action takes place, and the carbonic acid descends and gradually saturates the water in the lower globe. When this has taken place the aerated water can be drawn off by opening a stop cock at the top. Ales, wines, etc., may all be quickly aerated in the same way. By using a little fruit syrup very delicious beverages are produced.

Although the apparatus employed in Great Britain differs in construction and working from that used in the United States, still all apparati comprise two requisite parts—one for generating a gas and the other for mixing the same with plain water or with water containing the requisite salines or flavouring syrups.

Gazogènes are usually protected by network, but are still liable to burst or explode if not properly managed, and several serious accidents have occurred through careless or incompetent persons overcharging them. They are much more extensively employed in France than here.

Gazogène Powders.—The 2-pint size are retailed at 2d. or 3d. each; 3-pint size from 2½d. to 4d. each. Powders for 2-pint size should consist of 280 grains of powdered tartaric acid and 340 grains of bicarbonate of soda; for 3-pint size 340 of the former and 420 of the latter. The acid and the soda are usually packed in different coloured papers.

Gelang. —A fermented liquor made by the Malays from rice.

Gelatines, or **Grenetines.**—These are made by various processes from gelatinous animal substances, such as the cartilages, tendons, membranes, clippings off skins, bones and horns of animals, fish-scales, etc., in much the same way as glue is made. The material is usually boiled and treated with acetic and sulphuric acids, skimmed, strained, refined, and purified, to a greater or lesser degree of excellence.

The coarser kind of gelatine, got from hides, heads, hoofs, and horns, is generally made into *glue;* that from finer skin, such as that from calves' heads and membranes, *size.* In making gelatine proper the crude jelly first obtained has, of course, a very bad smell, but this is deodorised, and the substance, after being submitted to a heat of about 250° Fahr., and to various patent purifying and clarifying processes is finally poured hot on cooling slabs, cut up and dried on nets, or else rolled into thin transparent sheets, and may be sold either in that form or cut into thin shreds (straight or curly) or into lozenges.

Cox's Edinburgh Gelatine is said to be made from the South American ox. *Mackay's* of Edinburgh, from calves' feet. *Swineburne's,* from calfskin. *Nelson's,* from cuttings from the hides of beasts and calves. Real gelatines are only found in the animal kingdom, but they are sometimes substituted by or adulterated with so-called *vegetable* gelatines. This soft, tremulous, jelly-like mass obtained from fruits, vegetables, sea-weeds, etc., is spurious gelatine, and merely results from the half solution of organic principles known as pectine and pectic acid, *pectis* being, in fact, the Greek word for jelly. Medical opinion has, however, changed very much of late years as to the value of gelatine. Majendie has proved that dogs cannot live on jelly alone, and Liebig has clearly shown that gelatine is endued with no nutritive properties whatever, and that, unlike sugar and starch, it does not even minister to the development of animal heat.

The most beautiful gelatines come from France, where they are treated quite artistically, some clear as glass, and others variously and fancifully coloured. The French seem to run their sheets out marvellously thin, which gives them greater transparency and apparent freedom from colour, thus tempting the eye with great delicacy and purity, which transparency would at once disappear if made up into thicker sheets. Whether they are all really good or not, or what they are made from, is somewhat doubtful. Report says that rat skins, old kid gloves, etc., are utilised for the purpose of making gelatine in that country. Sometimes to free gelatines from unpleasant odours or to hide them, the products, besides being deodorised with antiseptics, are afterwards perfumed with musk, camphor, etc. Occasionally they are adulterated with salt, sugar, etc. Inferior gelatine is often of a dull colour, has an offensive smell, and makes goods taste tainted. To test gelatine, first soak it in cold water, then add some boiling water, when it should form a thick but clear and odourless solution; if a nasty smell arises, and it turns yellow and gluey, it should not be used for food. Gelatine has the power in a remarkable degree of solidifying a large quantity of liquid. In itself it is taste-

less, insipid, and of but little nutritive value; it is the wine or other flavouring that makes it agreeable; used alone, it would not keep a cat alive long. Gelatine is largely used by manufacturing confectioners in making calves' foot jelly, jelly tablets, soups, lozenges, etc., and by chemists for coating pills and other nasty drugs for swallowing. It is also employed by manufacturers as sizing for straw hats, for dressing crape, silks, blonds, laces, tulles, etc., and for a variety of other purposes.

Usually packed in 1lb. packets and sold wholesale in bags or cases of 1 to 4 cwts. each. To test the quality melt the gelatine, and the nearer it approaches to glue or size in smell or taste the worse it is.

Although hot water dissolves gelatine, which sets by cooling, it should be remembered that this property disappears after too long a boiling, and the liquid that remains will not again coagulate.

Leading Merchants.—J. A. Sharwood & Co., Ltd., St. George's House, London, E.C.; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.; M. E. Holdsworth, 3 Norfolk Street, Bradford.

Gelatine Lozenges.—These consist of a solution of gelatine, highly flavoured with lemon, together with a slight taste of acid.

The solution is run on glass plates into sheets about one-sixteenth of an inch thick, allowed to solidify, and then removed and cut up flat, either with round punches, cutters, or by self-delivering cutting rolls. Being too hard to be cut by hand, these lozenges are awkward to make, and there are only three or four firms in England who attempt them.

Gelatine Paper, or Foil.—These various coloured glossy sheets of gelatine (sometimes called *Leaf gelatine*), and more or less transparent, about as thick as sheets of paper, are mostly made in France, where their production, although quite simple, forms a special branch of industry.

They are made either plain, coloured, or painted, with neat designs in gold or silver. Pure gelatine, or even ordinary glue, is allowed to swell out in water, and then dissolved in a water-bath. When the solution has partly cooled, the aniline colouring matter (previously dissolved in water) is added. If ordinary glue is used it requires clarifying with ¼ oz. of oxalic acid to every 6lbs. of glue. If only one side is to be glossy the gelatine solution is poured upon a ground glass plate, but if both sides are to be glossy it is dried between two glass plates (previously rubbed with Spanish chalk). Greater pliability is given to the foil by adding to the warm solution ½ pint of spirit of wine and ¼ oz. of sugar candy, or a small quantity of glycerine.

Gelatine foil or paper is largely employed in making artificial flowers, visiting cards, labels, sacred images, etc., and by confectioners in making cosaques, cake ornaments, and in wrapping small transparent packets of sweets. Prices of these leaf gelatines vary from 8d. to 1/9 per lb., according to fineness.

Gelatine Sweets.—(See also *Gum Drops*, *Jujubes*, etc.)—Gelatine and gum goods are made in many forms and shapes, by running into moulds while in the liquid condition. The usual substance in which the moulds are made is farina or potato starch. The dried and powdered starch is placed in trays and the surface smoothed and levelled. A wooden board is then taken bearing casts of the particular shape required, and pressed firmly on the smooth surface. By this means a mould is obtained in the dry starch. The liquid gelatine may then be run in from conical vessels by hand, or by a travelling machine, which runs over the trays. This travelling filter consists of a receptacle for the mixed material, carrying at the bottom spouts corresponding in number to the moulds in one row. The quantity of material passing to the moulds is regulated by a piston to each spout. The machine is placed on the special rims and the spouts arranged over the first row of moulds; by a rapid movement they are filled simultaneously, and the machine is pushed to the next row which is filled in a similar manner. The hands who work these machines become very quick and expert.

The moulds when entirely filled are put aside to set and dry, and then the goods are sifted out. In some cases this is done by hand. The tray of starch containing the set goods is tumbled into a bin, and the pastiles recovered by means of a sieve. The goods are, however, still more or less covered by starch, and so they are passed to other workpeople who brush them, and finally by means of hand-bellows or pipes connected with fans, clean them entirely from the starch. But in the principal factories a cleverly-invented machine does all this work. It stamps the moulds, fills them, and sifts out and cleans the goods at one operation. A tray filled with the goods in the mould is emptied into the hopper, and the empty tray placed at the end of the machine. The pastiles are sifted out, and the starch falls into an empty tray beneath, which has in the meantime been brought under the hopper by revolving chains. The goods are cleansed by an air current and shot out at the side, while the replenished tray moves on under a board which smooths and levels the surface. The moving tray is next brought under the cast which imprints the moulds, and finally moves beneath the filler, from which the moulds are filled. The trays thus emerge ready for setting again.

Genepi.—A French liqueur manufactured from Alpine plants. It is of very ancient origin, and chiefly consumed in the district around Lyons.

Genevrette.—F. *Genevrier.*

A kind of wine made on the Continent from wild flowers and juniper berries.

Genoa Paste.—See *Italian Paste, Macaroni, Vermicelli,* etc.

Gentian-root (*jen-shan*).—F. *Gentiane;* G. *Enzian;* W. *Crwynllys.*

Also known as *Felwort.* The dried root of a tall and handsome herbaceous plant (*Gentiana lutea*), with blue or yellow flowers, growing three or four feet high in mountainous districts of Burgundy, the Alps, Pyrenees, etc.

The whole plant is very bitter, but the roots only are sought after. They are generally dug out by peasants, and in commerce they are met with in tough brittle pieces from a few inches to about a foot in length, with thick bark of yellowish brown colour externally, and wrinkled. Gentian root tastes sweetish at first, but ultimately very bitter; forming an excellent stomachic, and is largely used in pharmacy.

Other species of the gentian plant, of which there are over 500, are often substituted, or mixed with the true or officinal root. A large amount of gentian extract is used by publicans and others in fortifying beer weakened by watering.

Gentian Spirit.—A bitter liquor made from gentian root. It is very popular with the Swiss mountaineers.

Geranium Oil.—*Ginger-grass Oil, Rosa Oil,* etc. These are cheap substitutes for otto of roses. Genuine oil of geranium is obtained by distilling the leaves and flowers of *Pelargonium capitatum,* or *Andropogan schœnanthus,* grown in Northern and Central India, with water. It is nearly colourless, but with greenish or yellowish tinge, somewhat resembling rose oil.

The best is now distilled in the Kandeish district of the Bombay Presidency, whence it is sent down to Bombay for sale by native brokers, and has recently become an important article of export. It is so closely allied to rose oil that it seems almost impossible to distinguish between them.

Turkish geranium, Rusa, or *Ginger-grass oil,* is obtained from *Andropogan schœnanthus* (ginger-grass), a plant cultivated in Persia, Arabia, and East India. It was first introduced about 1825, is of a deep yellow or brown colour, with the odour of rose oil and the oil of red thyme, but inferior to the true geranium oil. (See also *Lemon Grass.*)

The product is also extensively prepared from the rose geranium in Algeria, France, and Turkey, but is largely sophisticated with fatty oil. This fraud can be detected by the behaviour of the sample with dilute alcohol.

Pure geranium oil in two to three vols. of alcohol of 70 per cent. (by volume) at 20 degrees; if small quantities of fat are present the mixture is dull, or in case of large quantities, milky.

Patchouly, Cus-cus, and other perfumes are made from this oil.

Gerardmer Cheese.—This French cheese, often corrupted into *Géromé*, is produced in the Upper Vosges, taking its name from the little town of Gérardmer.

It is a soft make, of moderate quality, but highly appreciated by the labouring classes. It is made in the form of a disc about 8 inches in diameter by 3 or 4 inches in height, and is usually packed in a wooden box.

German Barm.—See *Yeast*.

German Paste.—A food for insectivorous singing birds, such as larks, thrushes, linnets, nightingales, etc.

It is mostly made of pea-meal, hard-boiled eggs, honey or sugar, butter or lard, hay-saffron and sweet almonds, say 1lb. blanched sweet almonds, 2lbs. pea-meal, 3 ozs. butter or lard, 4 grains saffron and the hard-boiled yolks of two eggs, with honey sufficient to make a paste; mix and pass through a sieve, or colander, and expose in the air to dry.

Another recipe:—Bruise a pound of rapeseed in a mortar and blow away the husks, then mix with powdered crumbs of stale bread. This will keep a week or two in a closed vessel; mix a little daily with hard-boiled egg.

German Sausages.—F. *Saucissons d'Allemande*; G. *Deutchlander Wurstchen*.

In Germany the varieties of sausages sold under distinct names are innumerable, and no country produces so great a variety, every district having its own favourite flavour of spice or herb. The universal consumption of these esculents probably accounts for the universal thirst for which that glorious country is deservedly famous! Those sent to England are first dried and then smoked, and are generally very wholesome and agreeable. English-made German sausages are also largely sold in the shops, and are generally made up in the same way as English sausages and then seasoned. The usual seasoning consists of four parts of salt, one ounce of black pepper with a little saltpetre, garlic, pimento, nutmeg, or sage. The sausages are then smoked for five or six days. A discussion once arose at the table of King Frederick William III. of Prussia on the taste of the pineapple, which everyone likened to that of the fruit he preferred to all others. His Majesty sent for a peasant boy, and, after bandaging his eyes, put a slice of pineapple into his mouth, asking, "What does that taste like?" "Sausage," answered the boy, without a moment's hesitation. The sausages of Brunswick, Gottingen, Gotha, and Frankfort are not less esteemed than the hams of Westphalia and Bayonne. The sausages of Nuremberg, as dished up in the "Blue Bell," delighted Goethe so much that he had them sent by express to Weimar.

German Wines. — Germany buys yearly about £1,000,000 worth more wine than she sells. Average annual production 51,705,610 gallons, thus occupying only tenth place among wine-growing countries.

The exports to England are now about a million gallons a year, value some £400,000.

The vineyards cover about 300,000 acres, and a great variety of grapes is grown. In the Rhine district the Riesling chiefly, Austrian and Kleinberger coming next; while at Assmanhaunshausen, at the foot of the Niederwald, the early Burgundy and Klebroth are grown, and produce the famous Assmanshauser red wine.

As in France, the *phylloxera vastatrix* has done much injury, but is fought by destroying the infected vineyards and the application of bisulphide of carbon.

German wines belong to what is known as the drier, lighter, and acidulous class of wines; requiring less alcohol in their manufacture than the French or Spanish, on account of the cooler climate, and are more specially adapted for the commencement of dinner. Most of them are "*white*" and of delicate aroma, but it is difficult to make them perfectly clear and bright, hence the origin of coloured glasses for their use.

Although the preparation of sparkling wines in Germany dates far back, it has only recently—under the protectionist policy—become a notable branch of the national industry.

In 1840, Kuhlow's "German Trade Review" gave the annual production as

250,000 bottles at most, but in 1873 there were 40 factories, and at present the sparkling wine factories have risen to 80, in which 8 to 10 million bottles are produced annually. All sorts of grapes can be used, but the early and late Burgundy and Klebroth suit best. In 1895 Germany imported about 3 million marks' worth of sparkling wines in excess of export. From France she imported 2,109 tons, and only exported 978 to Great Britain, 180 tons to Belgium, and 92 tons to the United States of America.

Alsace-Lorraine is the chief wine-growing district in Germany; it produced about 17,000,000 gallons in 1890, and the most celebrated wines are grown on the Rhine or its tributary rivers between Coblentz and Mayence, and are known as *Rhenish* wines; to the north of Coblentz the wines are of little comparative value. Wines of Saxony are of little worth. Meissen and Guben produce the best. Naumberg makes some small wines like inferior Burgundy. The choicest vintages are confined to a small district called Rheingan, which extends from Rhudesheim to Mentz (Wiesbaden Regency). The best vineyards are those of Bishofsheim.

The extreme durability of German wines is very remarkable, and this property most likely originated the custom of storing them in vessels of enormous magnitude.

The great *tun of Heidelberg*, made in 1751, was 30 feet long and 20 feet deep; the *Gruningen tun*, 30 feet long by 20 feet in diameter; the *Tubingen tun*, 24 feet by 16 feet, besides many others. Rhine wines in general are drier than the French white wines, and possess a delicate flavour and aroma called *gare*, which is quite peculiar to them.

The following are the sorts best known here :—

Assmanshauser.	Marcobrunner.
Brauneberger.	Niersteiner.
Deidesheimer.	Oppenheimer.
Geisenheimer.	Rauenthaler.
Grünhaüser.	Rothenberger.
Hochheimer.	Rüdesheimer.
Johannisberger.	Scharzberger.
Laubenheimer.	Sparkling Moselle.
Leisten-wein.	Steinberger.
Liebfraumilch.	Steinwein.

German Yeast.—See *Yeast*.

Geropiga, or **Jerupigia.**—A factitious liquor, made to imitate or adulterate port and other wines and beverages, and which used to be shipped in large quantities from Portugal as "wine."

This villainous compound is said to be made of one-third crude brandy and two-thirds unfermented grape juice, elder juice, etc., sweetened and coloured with brown sugar, rhatany root, logwood, etc.

Very injurious ingredients are sometimes discovered in it by analysts. (See *Port Wine*.)

Gervais Cheese or **Demi-Suisse.**—These are a small and very soft creamy French kind, now made by Mr. A. Gervais (sometimes mis-spelt "*Jervais*"), at Gournay, in Normandy, but were originally invented by that gentleman's father, who was a noted cook. They are made from a mixture of two-thirds milk and one-third cream. Three quarts of the mixture make a dozen cheese. This is set at a low temperature, and the coagulation takes about 48 hours. They require altogether about three days to make, and are eaten with sugar while quite fresh. These cheese are greatly prized in Paris, where they fetch nearly 3d. each (25c.). Each cheese, shaped like a small tumbler, and about 3 inches high by 2½ inches in diameter, is wrapped in paper and packed six in a light wooden box. Two or three truck loads of these delicious morsels go from the factory to Paris every day in Mr. Gervais's own railway trucks.

Gesho. — A native hop used in Abyssinia for making beer.

Gex Cheese. — A French kind, analagous to Roquefort cheese, and made from goats' milk in the Ain and Jura departments. It takes its name from the little town of Gex, which is its market centre. They weigh from 14 to 20lbs. each, and the greenish blue marbling is effected in much the same way as the marking of Roquefort.

Gex cheese is very highly appreciated locally, as well as in Savoy and around Lyons.

Ghee or **Ghi.**—A kind of liquid butter clarified, and largely used

throughout all Eastern countries, many parts of India, and an article of considerable trade. It is made from the milk of buffaloes and cows, and is boiled and coagulated by the addition of a little sour milk, called *Dhye*, before churning. After the butter is made, it goes rancid in a few days, and is again boiled, and all the water is extracted. A little salt and betel leaf is then added, and it is ready for bottling, when it will keep good for many years. It is not often relished by Europeans, but tropical climates preventing the use of hard butter as with us, ghee is highly esteemed by the natives, and preferred to olive oil. It is generally conveyed in dubbers or large bottles made of hide, and containing 10 to 40 gallons each. Considerable quantities are exported from Bombay.

Ghee or **Ghi.**—A name in India for fluid butter.

Gherkins or **Girkins.**—F. *Cornichons;* G. *Pfeffer-Gurken;* Sp. *Pepinos.* (See also *Cucumbers.*)

A small fruited variety of the cucumber, or small young cucumbers of the larger varieties gathered before maturity.

Large quantities are imported from Holland and France every year in hogsheads; the Dutch are sold at so much per hogshead, but the French by weight.

The parts of France noted for gherkins are:—Paris environs, for symmetrical appearance; Toulouse, for ordinary quality; and Burgundy, for fineness of flavour, but rather chubby and less sightly in bulk.

The gherkins are gathered almost immediately after the inflorescence is over, and while they are in the first stage of fructification. To be of *first quality* they should not exceed in size one's little finger, but in commerce they are met with in all sizes, although usually sorted into different grades. Some of the Paris growers and a few in Holland seem to possess the secret of cultivating varieties to any size required; but very few English gardeners can produce them of uniform size and shape. The best are not so smooth and bright outside, but covered with small protuberances like warts and of a dull dark green colour.

Retailers should beware of brilliantly coloured pickles. An artificial green colour is often given to gherkins—which in themselves naturally contain traces of copper—by heating them in copper vessels, and thus (by certain unknown chemical action) imparting to them a poisonous sulphate of copper, decidedly prejudicial to health, even in small quantities.

French picklers usually fill gherkins and green fruits into bottles of green glass.

For Gherkins, apply to Allen Jeeves & Sons, Seddington, Sandy, Beds.

Gin.—Arm. *Genevra;* F. *Genièvre, genivre;* It. *Ginepra;* Port. *Zimbro;* Sp. *Nebrina.* (See also *Hollands, Schiedam, Geneva,* or *Dutch Gin.*)

The word *gin* is either a corruption of *Geneva,* in Switzerland, celebrated for a similar liquor, or an abbreviated form of the French word *genièvre* (juniper berry).

Genuine gin is an aromatic spirit, or plain corn spirit, distilled from oats, rye, barley, or malt, and flavoured with essence of juniper berries. But instead of juniper the spirit is generally flavoured with the oil of turpentine, or creosote, and it has really become an artificial compound. It should be about half alcohol, and a very useful medicine in several diseases, especially of the kidneys and urinary organs. But almost every distiller or rectifier has his own mode of making or flavouring gin; indeed, British gin is now for the most part made by rectifiers of the low-wines of the Scotch and English spirit or whisky fabricators; and its alcoholic strength, as commonly sold, ranges from 20 to 48 per cent. of absolute alcohol, while the amount of sugar varies from 2 to 9 per cent. It must not, however, be sold weaker than 35° under proof without a special declaration of its strength.

Gin was originally, and for many years, wholly imported from Holland. After a time the distillation of an imitation of this sprung up in this country, and was known as *English Geneva,* or *Plymouth gin;* and the foreign spirit

was called *Hollands*, *Schiedam Hollands*, *Hollands gin*, or *Geneva*, to distinguish these from the home-made.

Gin used to be the popular drink with the lower classes in England, as was brandy with the aristocracy.

The year 1736 will be ever memorable in connection with gin. In that year its consumption had become so excessive that London and most large towns swarmed with drunken people from morning to night. It was very cheap; people could get drunk for a groat (4d.); and some retailers even exhibited placards in their windows that people might get drunk for a penny, and that clean straw was provided for customers in the most comfortable of cellars.

To stop its sale a duty of 20/- per gallon was imposed on gin, and this led to extraordinary agitation, riots, and violence during that and several years following, thousands of persons being imprisoned for violating the Act.

Old Tom.—The origin of the name "Old Tom" is uncertain. Some writers say it was given to a particular kind of gin distilled by one Tom Hodges in London; and more recently the firm of Boord & Co. have adopted this name and the figure of a tom-cat as a brand for their product. Others, however, state the term "Old Tom" arose about 1706, when the sale of gin in less quantities than two gallons was made illegal. A Captain Bradstreet fixed to a house taken for the purpose of evading the letter of the Act an old sign representing a cat, with a secret tube extended into the house; customers placing their money in the cat's mouth received a supply of gin through the tube without seeing or being able to swear by whom they were served.

English gin, as now sold by publicans, is, however, often vilely adulterated, fortified, or doctored, with more or less injurious concoctions—such as potato spirit, oil of turpentine, cocculus indicus, and roach alum—the latter being used to clarify it—carbonate of potash, tartar, and grains of paradise; concealed by the addition of salt, cayenne, coriander, fennel, crushed almond cake, liquorice root, cassia, cardamoms, or other aromatic flavouring substances. Alum can always be detected. Oil of vitriol is also used, and oil of almonds; that is for beading—in pouring the gin into a glass it must form a series of little bubbles which hang on the periphery of the glass. One dram of oil of vitriol, 1 of oil of sweet almonds, mixed in a mortar and with some stronger spirit, gives a beading to 100 gallons of gin.

Cordial Gin is a syrupy quality, more heavily sweetened, and aromatised with essences, spices, etc.

Tom and Jerry, another name once very common for gin, arose from Corinthian Tom and Jerry Hawthorn visiting Bob Logic in the Fleet Prison, and obtaining the prohibited liquor by whistling.

Ginep.—A name for the fruit of the *Melicocca bijuga*, which is very common in the West Indies, and occasionally imported into England.

Gin-fizz.—An American drink composed of gin, lemon-juice, and effervescing water, with or without sugar.

Gingelly Oil.—(Also known as *Ginjili Oil*, *Benne Oil*, *Til* or *Teel Oil*, *Oil of India*, etc. See also *Sesame Oil*.)—A bland fixed oil, expressed chiefly at Trieste, and Marseilles, in France, from Levant gingelly seed (*Sesamum orientale*), which yields about 50 per cent. of oil of three qualities:—about 30 per cent. of *surfine* from the first pressure; 10 per cent. of *froissage* from a second pressure, after the cake has been softened with cold water; and 10 per cent. of *rabat*, after the cake has been subjected to steam or hot water.

Gingelly oil is a valuable article of commerce, free from smell, does not readily turn rancid on exposure to the air. It is often mixed with or substituted for olive oil, and is used largely in soap-making; but in warm countries it is very popular in cooking.

Gingelly, Til, or Benne Seeds.—The seeds of the *Sesamum* or Benne plant, of which there are three varieties, the two best known being *Sesamum indicum* and *Sesamum orientale*. The plant is an annual, growing two to four feet high. It is a native of India, but now cultivated in most warm countries,

The leaves are very mucilaginous and readily impart this quality to water. The white seeded is called *Suffed-til*, and the black seeded *Kala-til*. The seeds have from ancient times been classed with the most nutritious grains, and yield about half their weight of oil (see *Sesame Oil*), and still form an important article of food in Asia and Africa. Large quantities of these seeds are imported into France, England, and America. They are often used by jam makers to imitate fruit seeds.

Ginger.—Ar. *Zingebeel;* Ben. and Hin. *Ada;* Da. *Ingefær;* Du. *Gember;* F. *Gingembre;* G. *Ingwer;* Ind. *Zingiber;* It. *Zenzevero;* Per. *Zunjebeel;* Port. *Gingivre;* Rus. *Inbir;* Sp. *Genjibre;* Sw. *Ingefara;* W. *Sinsir.* (See also *Mango Ginger, Galangal, Preserved ginger, Ginger marmalade,* etc.)

GINGER.

This well-known spice is obtained from the knotty fibrous roots of *Zingiber officinale*, a reed-like perennial plant, native of China and the East Indies, but also found growing wild in East Africa and Mexico, and now cultivated in several tropical countries, especially in Jamaica. (See *Jamaica Ginger.*) The sorts commonly met with are Jamaica, Cochin, Bengal, Tellichery, Japanese, and African, and these range in value from 90/-, 50/-, 40/-, to 28/- per cwt. They may be bought in various conditions —whole, ground, washed, unwashed, spent, scraped, and cut. A number of tea planters in Madras have taken up the culture of ginger. As the movement is in its infancy, it is as yet impossible to say if it will be a financial success. It flourishes best on rich well-drained clayey loam, from small pieces of the tuber planted about four inches deep and nine to twelve inches apart. In Jamaica it is planted in March or April, after which the whole ground is soon covered with long green leaves, alternate, nearly like maize leaves, and little flowers slightly tinged with green appear in September, when the stems of the plant are three to four feet high. The flowers and leaves rise from separate stems, those of the former are shorter than those of the latter, and only average from six to twelve inches in length.

The flowers having withered and seeded, the roots are dug up about the latter end of January. If left too long in the ground the tubers put forth stems, and then become fibrous, but if taken up earlier they are only about five or six inches long, very succulent, and suitable for preserving (see *Preserved Ginger*). The real *roots* of the ginger plant are the thin fibres which are given off from the knotty tubers, *races*, or "hands," as these are termed in commerce. The yield per acre is about 4,000lbs. Ginger may be cured as either bleached or unbleached.

The "*Black*" or *Stone-brown Whole Ginger* of commerce usually consists of the older tough or horny roots, and have been simply discoloured by scalding them in water and then drying in the sun. They are of inferior strength and flavour.

Whole White Ginger is usually of a superior quality, selected and prepared from the best and soundest "hands" and "joints" by scraping off the outer dark-coloured part and then carefully drying without scalding.

The bleaching or coating of gingers is usually performed after they reach the first markets, and is effected by burning sulphur or chlorinated lime and then covering with the sulphate or carbonate

of calcium, so as to protect it from the ravages of insects. The chief sorts are Cochin, Jamaica, and African. The best Cochin is the unbleached, new, dry, plump, heavy, and pale buff coloured. It is chalky or mealy inside without worm holes, and cuts softly and evenly.

African Ginger.—While unsuitable for many purposes on account of its coarse appearance and dark colour, harsh flavour, and inferior aroma, it really yields the highest percentage of oleo-resin, viz., 6 to 9 per cent., and the most pungent essence.

Whole Ginger, especially coarse African, is largely employed in making ginger beer, ginger essences, extracts, etc.

Washed Ginger is, or should be, ginger which has been cleansed in acidulated water to protect it from worms, etc.

Green Ginger is usually imported in casks, and in this state is used by wine makers, preservers, etc.

Leaf Ginger is ginger which has been sliced up into thin flakes.

Spent Ginger, often sold to grocers as "*Washed*" *Ginger,* consists of whole ginger which has been boiled, steamed, or otherwise exhausted in making cordials, ginger beer, etc. Frequently the best ginger is treated with a solvent, generally alcohol, whereby the extractive matters capable of being extracted are obtained, leaving only the woody fibre and starchy matters.

The extract is largely used by aerated beverage makers and confectioners.

The residuum (spent ginger) is afterwards sold at the factories at £2 to £5 a ton.

It generally falls into the hands of parties who either bleach it and dry it, or grind it up into powder. This is finally palmed off on to retailers, either as genuine whole ginger or mixed with pickling spice. If ground, it is either sold separately or mixed with other ground ginger, but, of course, these uses are illegal and subject the retailer to fine. Sometimes it is ground up and mixed in ground pepper.

Spent Ginger, of course, lacks the more valuable properties of the vital constituent, namely, the essential oil, and has little taste or smell of ginger, although it may contain certain ill-defined resinous bodies, and a slightly pungent taste. When whole, a hard, horny shell of dark colour may be noticed on cutting ginger that has been boiled and redried, while if it has undergone alcoholic extraction, usually weak spirit of wine, it will probably have a light, crumbly, disintegrated appearance. All the authorities are agreed that the percentage of soluble ash (soluble mineral matter) is the all-important factor for determining the proportion of exhausted or spent ginger in a suspected sample. Ginger cannot be extracted by water or by weak spirit of wine without removing a corresponding proportion of this substance, and its normal proportion never falls below a certain figure. The lowest on record is 1·41 per cent., and it is the only one. The next lowest are 1·70 and 1·71, so that 1·70 is a very low standard indeed to base upon. The average is 2·18, and the maximum 3·05 per cent. of soluble ash.

Ground Ginger.—The common adulterants to be expected in ground ginger are turmeric, wheat flour, husk of mustard seed, sago, etc. (See Section 9 of the Food and Drug Act of 1875.)

The following table shows ordinary mixings for eleven qualities of ground gingers. It will be noticed that only the first *four* are genuine, and the remainder compounds.

Quality.	Cochin G.	Jamaica G.	African G.	Rice flour.	Wheat flour.	Colouring.	Total in lbs.
1	14	—	—	—	—	—	14
2	2	1	—	—	—	—	3
3	2	1	1	—	—	—	4
4	1	—	5	—	—	—	6
5	6	4	—	3	—	2	15
6	—	14	—	2	—	1	17
7	4	—	4	3	1	2	14
8	21	21	7	21	—	10	80
9	4	5	5	20	—	5	39
10	—	14	14	42	42	25	137
11	—	—	28	42	42	25	137

The *colouring* compound used consists of equal parts of potato flour and wheat flour, to which finely ground turmeric of best quality is added.

The chief use of ginger is as a condiment or spice, but it is also used as an aromatic and stomachic medicine. The stimulant, aromatic, and carminative properties render it of much value in atonic dyspepsia, especially if accompanied with much flatulence, and as an adjunct to purgative medicines to correct griping. Externally applied as a rubefacient it has been found to relieve headache and toothache. The rhizomes, collected in a young green state, washed, scraped, and preserved in syrup, form a delicious preserve. Cut up into pieces like lozenges and preserved in sugar, ginger also forms a very agreeable sweetmeat.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

For genuine Gingers, apply to Hedley, Gamble, & Crosfield, Circus Street, Liverpool; or W. & D. Harvest, London.

Gingerade.— An aerated beverage flavoured with ginger.

Ginger Ale.—(See also *Temperance Drinks.*)—An effervescing drink similar to ginger beer, with a little harmless colouring matter to simulate that of ale, and probably so called for sake of variety. Messrs John Gratton & Co., chemists, Dublin, were the original makers, but they neglected to patent it. A bottle is easily made from a few drops of essence of ginger, or capsicum extract, sugar, and colouring, and then filled up with carbonated water (see *Aerated Beverages*). Occasionally a little mucilaginous or similar matter, known as *Froth*, *Heading*, etc., is added to give a "good head."

Ginger Ale Powder (Belfast).— Powdered white sugar, 16 ozs.; bicarbonate of soda, 3½ ozs.; powdered citric acid, 4½ ozs.; essence of ginger 1½ ozs.; essence of cayenne, 4 drms.; and essence of lemon, 40 drops.

Dry the soda, acid, and sugar very carefully; before drying the sugar, incorporate with it the essences thoroughly, to which a small quantity of caramel may be added as colouring.

Gardner's patent "Rapid" sifter and mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Ginger Ale Syrup. — Mix 2 ozs. tartaric acid, 6 drms. caramel, 4 drms. liquid extract of quillaia, and 8 ozs. of water; when filtered pour it into 7½ pints of sweetened water (plain syrup) and add the following mixture:—2 ozs. soluble essence of ginger, 1½ drms. tincture of capsicum, 1 drm. essence of vanilla, and 3 drops of oil of cinnamon.

Ginger Beer. — An effervescing beverage made by fermenting ginger, cream of tartar, and sugar with yeast and water, and bottling before the fermentation is completed. The carbonic acid generated within the fluid gives, after a few days or weeks, an aerated drink; but this variety of ginger beer is also an alcoholic drink, for the fermentation which is set up by the yeast in a part of the sugar gives rise to a little alcohol, as well as to carbonic acid. Two per cent. of alcohol is the strict legal limit, but it often contains 3 or 4 per cent. (See "*Non-alcoholic Beverages.*")

There are numerous recipes for ginger beers, but none of the *brewed* products will keep good for long in varying temperatures, so that they cannot be conveniently exported to distant hot climates:—

1. Pour a gallon of boiling water upon ¾lb. of loaf sugar, 1 oz. each of ground ginger and cream of tartar, and the peel of one lemon. When cool add the juice of the lemon and a tablespoonful of yeast. Cover it, and let it stand till the next day; then strain it, taking care not to stir up the sediment, bottle it in stone bottles, tie down the corks, and it will be fit to drink in two days.

2. 1lb. lump sugar, 1 oz. bruised ginger, ¼ oz. cream tartar, a sliced

lemon, and a gallon of boiling water. Mix, and when lukewarm, or 70° F., add 1 oz. of yeast, stir and let stand for 24 hours, skim, strain, and cork in stone bottles.

3. Take 3½ ozs. of cream tartar, 4 ozs. powdered ginger, 2lbs. sugar, 2½ ozs. lemon juice, 2 gallons water; digest when lukewarm; add 1 oz. of German yeast; skim and bottle tight.

4. To 1¼ oz. cream of tartar add 1½ oz. bruised ginger, 2lbs. white sugar, the peel and juice of two lemons. Bruise the ginger and lemon peel with ½lb. of sugar in a mortar; put all together in a pan, and when lukewarm two tablespoonfuls of good yeast; let this ferment ten hours, drain clear, cork tight and tie down; will be fit for use in ten hours.

5. Boil 22 ozs. bruised ginger in three gallons of water for thirty minutes; add 20lbs. white sugar, 18 ozs. lemon juice (or eighteen small lemons sliced), 1lb. honey, and fifteen gallons water. When cold add the white of one egg well mixed with a quart of the liquor. Let stand three or four days, then strain and bottle.

6. Aerated ginger beer is also manufactured by merely passing aerated or carbonised water into bottles containing a little syrup of ginger.

7. Mix 3lbs. moist sugar, 8 ozs. of crushed (not ground) ginger, ½ oz. tartaric acid, ½ oz. cream of tartar, and put all into a tub or pan-mug, and pour on four gallons of boiling water; stir well, and when nearly cool mix ½ oz. German yeast in a little of the liquor, and then add it to the rest. After standing 12 hours, skim, bottle, cork, tie down, and pack them away upside down.

A more palatable beverage may be made by using more sugar, but that will soon produce more alcohol than the Excise permits to be sold without a spirit licence. Many shopkeepers have been heavily fined for selling such, and for this reason saccharine is now largely used instead of sugar.

The *Ginger Beer Plant* is an impure yeast or leaven, different from ordinary brewers' yeast (*Torula*) or German barm, although a microscopic fungus closely allied to the former. The cells are of various shapes, and are bound together by myceloid filaments, which increase with the free access of air. The peculiar flavour imparted to the liquid has been attributed to small bacteroid cells. It has the remarkable property of effecting the fermentation of saccharine solutions containing ginger, and is largely employed for home-made ginger beers, commonly put up in stone bottles. (See also *Ginger-pop*.)

Ginger Beer Powders. — These are put up in packets ready mixed, by most wholesale druggists and manufacturing drysalters, and the following recipes may be quoted as examples:—

1. 4lbs. carbonated soda, 4¼lbs. tartaric acid, 16lbs. icing sugar, 1lb. best ground ginger, all well dried and mixed, and then flavoured with 1 oz. essence of lemon, and passed through a fine sieve. It should be bottled and well corked and kept in a dry place. A large teaspoonful of this stirred in half a tumbler of cold water makes a very nice ginger beer.

2. Bicarbonate of soda, 30 grains; white sugar, 1 drm.; powdered ginger, 5 grains; mix for each blue paper. Put 25 grains of tartaric acid in each white paper. Both to be mixed in a tumbler of water.

3. Sugar, 2 drms.; sesqui-carbonate of soda, 2 scruples; ginger, 4 or 5 grains; essence of lemon, 2 drops; mix for each blue paper; and in each white paper put 35 grains of tartaric acid.

4. Sugar, 10 ozs.; carbonate of soda, 624 grains; ginger, 192 grains; mix for twelve blue papers. For twelve white papers divide 360 grains of tartaric acid.

5. Use lemonade powders, and add to the waters some essence of ginger while mixing.

Special Firm.—John May, 114 Church Street, Croydon, packs good ones at 2/6 per doz.

Gingerbread. —F. *Pain d'épices.* Made of wheaten flour, treacle, or

golden syrup, moist sugar, butter and eggs, and flavoured with ginger, mixed spice and lemon peel. Sometimes carbonate of ammonia or tartaric acid is used to make it light.

The top is usually glazed with a solution of gelatine, say 1 oz. dissolved in a pint of water. It should be painted on directly the gingerbread comes out of the oven.

Another way: Mix 6lbs. flour and a little ground ginger with three pints of treacle, and knead into a good stiff paste.

Besides its classic pavement form gingerbread has for centuries been made all over Europe in many quaint shapes, such as crowns, mills, animals, noted personages, etc., and frequently decorated with comfits of various colours, icing-currants, stains, etc. Although the late M. Thiers once remarked that no man could call himself truly great until seen in gingerbread, these ancient forms are now oftenest met with at fairs and in remote country districts.

Scotch Gingerbread.—Take 9lbs. flour, 6lbs. golden syrup, 2½lbs. butter, 3lbs. moist sugar, 1 oz. ground nutmeg, 1½ oz. mixed candied peel, ½lb. chopped almonds, and about 16 drops essence of pear (if wanted lighter, add 1 oz. cream tartar and ½ oz. carbonate of soda). Simmer the butter and sugar in the syrup, let it get cold, then mix into the dry ingredients. Make out 3lb. or 4lb. blocks, with impression on the top, or into smaller sizes, and bake in a solid oven. Use glaze when baked.

Several old provincial towns—Ormskirk, Congleton, Grantham, Grasmere, Wrexham, Whitby, etc.—have long been more or less famous for their respective gingerbreads, gingerbread biscuits, spice cakes, etc.

In France, Paris, Rheims, Dijon, and many other towns have also long been noted for their "Pain d'épices"; rye flour is used, and in the best qualities honey instead of syrup, while the upper surface is often ornamented with split almonds, lemon or orange peel, angelica, etc. (See *Nonnettes.*)

Gingerbread Plums.—The large farinaceous fruit of the gingerbread tree (*Parmarium macrophillum*), a rosaceous tree of Western Africa.

Ginger (Candied).—A stomachic sweetmeat consisting of the young root-stocks of ginger.

Ginger Cordial. — An aerated beverage flavoured with ginger.

Ginger Essence. — An alcoholic tincture popularly used as a culinary flavour. It is made in several ways:—

1. 6 ozs. sliced ginger, 12 ozs. rectified spirit, 4 ozs. water, 4 ozs. lump sugar, 2 drms. cardamom seeds; macerate twenty-one days and filter or else percolate.

2. 1lb. ginger, 4 ozs. cloves, 2 ozs. cayenne, 1 pint rectified spirit, 2 pints proof spirit; macerate fourteen days and filter.

3. 1 pint rectified spirit, 6 ozs. unbleached ginger, digest fourteen days and filter.

Gingerette.—How made: Infuse in 1 pint of pure spirit (or gin or whisky), 3 ozs. bruised ginger, strain with pressure; add 1½lbs. of sugar and 2½ drms. of citric acid; dissolve in three pints of water.

Ginger-grass Oil.—See *Geranium Oil.*

Ginger Marmalade is easily made by slicing jarred ginger and reboiling it with the syrup, adding a liberal proportion of glucose and water. Profit, cent. per cent.

Ginger Nuts (Biscuits).—Of course, in factories, they are made by elaborate machinery, but the following will afford an idea of their composition:—4lbs. flour, 2lbs. moist sugar, 1lb. butter, 2 ozs. ginger, 2 ozs. golden syrup, ¼ oz. carb. soda, and 8 drops lemon essence.

Mix butter and sugar, then rub them into the flour, and afterwards mix the whole with the syrup; roll out on sheet and cut out, wash with milk and bake in slow oven.

Ginger Pop.—A weak or inferior make of gingerbeer.

Ginger Snaps.— Thin brittle biscuits flavoured with ginger; or, an inferior kind of ginger nuts, and usually about the same size, but darker in colour.

A small mixing would be 2 quarts of molasses, 1 quart water, 18 or 20lbs. flour, 2½lbs. lard, 4 ozs. ground ginger, and 5lbs. light coloured moist sugar. Mix in the usual manner, roll, cut with plain round cutter, add a little cinnamon or cassia, and 2 ozs. saleratus.

Ginger Tea.—A very useful remedy for flatulence, and usually made by infusing root or whole ginger in boiling water.

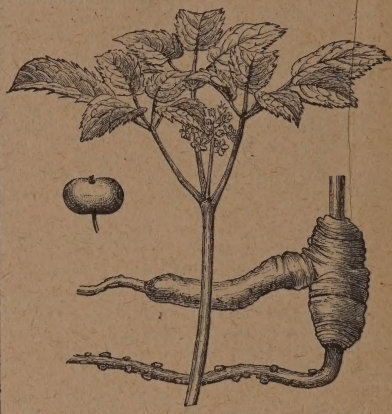
Ginger Wine.—(See also *Unfermented Wines.*)—A British wine or liquor, generally made with water, sugar, lemon rinds, ginger, yeast, raisins, and frequently fortified with added spirit and a little capsicine.

Ginger Wine Essence.—A mixture of burnt sugar and "gingerine," acidulated with tartaric acid, and flavoured with a few drops of lemon oil; but a superior quality is made from 3 fluid ozs. of essence of ginger, ½ oz. soluble essence of lemon, 1 oz. tartaric acid, 2 fluid ozs. liquid caramel, 1 drm. tincture of capsicum, 20 minims oil of ginger, with syrup (sugar and water), to produce 8 fluid ozs.

Ginseng.— G. *Kraftwuzel;* Ind. and Per. *Chobchini;* Port. *Ginsilo.* (Also known as *Chinese-wood*, *Ginsani*, and *Schinseng.*)

The root of a kind of ivy, *Panax quinquefolium*, in Chinese Tartary and in several parts of Corea and Japan. The dried root as imported is about the size of one's little finger, frequently forked, transversely wrinkled, of a horny texture, and of a yellowish white colour both inside and out. It was formerly thought to be a very valuable medicine, but in Europe this belief has been well-nigh exploded. The wealthy Chinese, however, still ascribe extraordinary virtues to it, and are its chief buyers.

Wild Manchurian ginseng in China used to be worth its weight in gold, marvellous "repairing" qualities being attributed to it.



GINSENG.

The production of ginseng is the chief industry of Song-do, in Corea. The country around that city is nearly all given up to the cultivation of the plant, which is highly esteemed as a food tonic by the natives, but especially by the Chinese and Japanese. The seedlings are planted in rows in raised beds, and are protected from wind and rain by a reed-thatching some 3 feet in height. The annual crop in Corea is about 15,000 catties.

Red ginseng, so-called, is only made at Song-do, and is specially prepared for the Pekin market. The roots are placed in wicker baskets, enclosed in earthenware pots with holes in the bottom, and then set over boiling water and steamed for one to four hours, according to the age of the plant. It is afterwards dried until it assumes a hard, resinous, translucent appearance, which is a proof of its good quality. Two catties of the "*white*" or natural ginseng are required to make one catty of the clarified product.

The "*White*" *ginseng* is widely consumed in the form of broth by the Coreans, who have long had the greatest faith in it as a cure for all

forms of disease. The roots having been well stewed, the Corean epicure wraps a napkin round them, squeezes them, and then drinks the juice. *Quinine* is, however, said to be superseding the use of ginseng among the natives.

In England it is made up into lozenges; also a much-vaunted wine. There is another variety, known as *Panax quinquefolium*, which grows chiefly in Canada and the northern United States. The roots are not used until the plant is six years old. It was for a long time looked upon as a weed, till the Chinese immigrants recognised it, and it is now highly valued in China.

Gin Sling is a corruption of the name *John Collins*, a London waiter, who invented a famous cooling drink composed of gin, soda water, lemon, and sugar.

Glass Cloth and Glass Paper.—(See also *Emery Paper*, etc.)—These are prepared by covering paper or thin cloth with glue and then scattering finely powdered and sifted glass over it, old wine bottles often being ground up for this purpose.

Glass Paper is sometimes miscalled *Sand Paper* (which see). They are made extensively at Birmingham, and sold in sheets. Used for polishing fine wood and metals, which require a superior polish. The cloth is not so brittle as the paper.

Glauber's Salt.—This is a sulphate of soda, and is usually made in winter only by decomposing common salt with sulphuric acid. It also occurs in sea water and in some mineral waters, as in those of Püllna, Carlsbad, etc.

In Wyoming, U.S.A., there is in the oil district a lake of glauber salt covering about 110 acres. It consists of a solidified mass of practically anhydrous sodium sulphate, with 6 per cent. of carbonate, 1·5 per cent. of chloride, and 6·9 per cent. of water of crystallisation. Glauber salts are also got from the Great and Little Marmishausk Lakes in the Tomsk Government of Siberia, 125 miles south-west of Barnaul. The total area of these two lakes is about 2½ square miles, and the layers of sulphate are about 2 feet thick, yielding over 1,500 tons a year.

Used mostly in the manufacture of soda, ultramarine, and glass, also as a purgative. Glauber was a German chemist.

Glaze for Cookery.—Usually sold in skins.

This consists of gelatine dissolved and mixed with caramel, burnt onions, or other colour, say about 3 ozs. of any good brand of gelatine to each quart of stock. The meat or joint is simply dipped in the fluid before the latter sets.

Another kind is produced by boiling a shin of beef and a knuckle of veal in 6 quarts of water. When seasoned to taste it is slowly boiled down to about 1 quart, and when required for use it is warmed up and brushed over the cooked tongue or other meat with a soft brush or feather. It is also often made by cooks boiling down some bottom stock. The hams or tongues must be perfectly cold and wiped dry before applying the glaze, which also must itself be nearly cold.

Glasgow Magistrates.—A jocular name for Red Herrings.

Gloucester Cheese.—A rich and highly coloured variety of cheese, made of two qualities—*Single* or *Berkeley*, round and flat, about 17lbs. each, and *Double*, weighing 28lbs. to 40lbs. each. The former is supposed to contain half, and the latter all the cream of the milk. They are both made by the sweet process, a smaller quantity of rennet being used in turning the milk, and this renders them mild tasted, delicate in flavour, and pleasing to most palates.

Gloucesters are generally made twice a day, the temperature at which the milk is set being 85° F. The curd should be collected with the utmost care, and cleanliness be the characteristic of every operation, and as the cheese is allowed to ripen slowly it is expensive to make, but when made

properly and matured perfectly it is an excellent mild cheese. The ordinary composition of a Single Gloucester has been given as:—Water, 21·41; casein and albumen, 49·12; fat, 25·38; and ash, 4·09. There is, however, a tendency to make both Single and Double Gloucesters of same quality, and often the only difference is in the size, the single being thin and the double twice the thickness. They are generally hard and good keepers, semi-buttery without being friable, and much milder than Cheshire. Also made in Wiltshire.

Occasionally they are made pale or white, but very rarely. Gloucesters after drying are usually scraped clean and painted with Spanish brown, but both the interior and exterior colourings are at best only fashionable mistakes.

Glove Powders.—Sometimes made from Castile soap, dried by exposure to a warm dry atmosphere for a few days, and then reduced to a fine powder.

Another is made of pipe-clay coloured with yellow ochre, umber, or Irish slate, and afterwards scented with a little powdered orris-root or cloves. Used for cleaning and colouring gloves made of doeskin and similar leather.

Glucose or Starch Sugar.—(See also *Grape Sugar*, *Dextrose*, etc.)—Glucose (so called from the Greek word *Glykos*, although Glycose should be the proper spelling), both in liquid and solid state, originally came from Germany. It first appeared in the London market in the seventies, and was quoted at 30/- to 32/- per cwt., but may now be bought at 7/- or 8/- per cwt.

The liquid glucose of commerce is a variable product, an imperfect sugar, prepared by the action of acids on starch. It is a very thick, white or water-coloured syrup, obtained from the starch of wheat, potatoes, also from wood and other vegetable substances, but chiefly from yellow maize (Indian corn). Liquid glucose is usually made much thicker than treacle, and may be rolled in cold wet hands and thrown like a snowball. Immense quantities are made, especially in America, where it is called *Corn sugar*. Buffalo is the chief seat of the trade, although one factory alone in Chicago turns out over 100 tons a day. Technically it is known as a mixture in varying proportions of two sugars called *dextrose* and *maltose*, and of *dextrine*, or starch gum, by submitting the starch to the action of dilute sulphuric acid, which is afterwards neutralised and removed as sulphate of lime; a small quantity of cane sugar is sometimes added to give flavour. Glucose is altogether inferior to cane or even beet sugar in sweetness, but is only about half the price. There is, of course, no sweetening power whatever in dextrine, whilst that of dextrose is infinitely less than that of invert sugar. Indeed, ordinary glucose has only about one-third the sweetening effect of cane sugar, but it is copiously used in making jams, marmalade, jellies, syrups, caramels, condensed milks, lemon-cheese, meat extracts, etc., which are sold by weight. Glucose is also used by tanners for the "weighting" of leather, as well as for the production of alcohol, sauces, piccalilly, and other pickles, for fermenting purposes, and particularly by brewers in sweetening and giving body to beer and pale ale. It is a frequent adulterant of honey, golden syrup, treacle, etc. The thickest and freest from colour is the highest in price; but reckoning the sweetening power of cane sugar at 100, that of white liquid glucose is only 30 to 40. Although the import now reaches about 100,000 tons a year, we know of no particular use for it except as an adulterant. The saccharine property was first discovered in raisins, and in its solid crystallised state is better known as *grape sugar* (which see), while glucose is the name popularly applied by chemists to the liquid form.

In Germany glucose is obtained chiefly from potato-starch, but the American product is preferred. The "hard" or "solid" product, contains a little of dextrine, and frequently gallisine, but the "liquid" contains

much more, and it is owing to these elements that glucose will not crystallise.

It matters not, however, from what material the starch is obtained so far as the quality of the glucose is concerned. It has been made from chips, sawdust, and shavings, and the chemical composition is invariably the same; but, as already shown, *yellow maize* has been found to be the most convenient material for making large quantities. It results from the acidulous fermentation of the starch or fecula. In the process of manufacture the starch is usually boiled with sulphuric acid and water, and the product, instead of being very sour, is found to be fairly sweet.

The acid changes the starch to sugar, but is not itself affected in the least. Powdered chalk is then thrown in, which unites with the acid and settles to the bottom, leaving a clear, sweet solution of liquid glucose. It is perfectly harmless, and even somewhat nutritious; in fact it is more assimilable than cane sugar itself; but although it is sometimes said to contain 80 per cent. of "sugar," that sugar bears no comparison with cane sugar in sweetness, and is nevertheless only a factitious sweetening article, consisting rather of amylaceous matter in a state of incomplete transformation. Common glucose often contains a slight impurity due to the presence of sulphates, but the best makes are practically free from sulphate. There is a considerable difference between brands of glucose, in fact no two firms make the same sort. Some are prepared with crude vitriol and lime (*calcium hydrate*), and in some cases oxalic acid is employed. Glucoses may also be the same colour and guaranteed "44 degrees," but not really of the same strength.

The kinds denominated "41" and "43" are chiefly used to imitate golden syrup.

Imports, 80,506 tons in 1897, 94,352 in 1898, and 91,280 in 1899; nearly all from America in 6 cwt. casks. Prices 6/- to 10/- per cwt. German glucose is generally in 8 cwt. casks. The solid is sold in 1 cwt. bags.

Special Importer.—M. E. Holdsworth, 3 Norfolk Street, Bradford.

Glue. — Da. *Liim;* Du. *Lijm;* F. *Colle;* G. *Leim;* It. *Colla;* Port. and Sp. *Cola;* Rus. *Klei;* Sw. *Lim;* W. *Glyd.*

This is made from the hoofs, hides, ears, tails, intestines, and similar kinds of animal garbage obtained from slaughter-houses, tanyards, etc., and may be termed an evaporated solution of the above, as well as those of old horses, diseased animals, etc.

The stuff is first soaked in tanks of quick-lime water for two or three weeks. This eats off all the hair, and at the same time acts as an antiseptic. The material is then washed and dried, and the process is repeated with stronger lime.

After this it is placed in network bags or in a copper vessel, with a perforated bottom fixed inside the outer one, so as to prevent burning, and there it is boiled slowly and gently, and skimmed from time to time, until it is fairly clear and evaporated to the proper consistency.

The solution is then run off and strained into square deep wooden cooling boxes wider at the top than at the bottom. These when full and partly cooled are turned out, and the jelly while soft is cut up by wires like soap into thin cakes, which are again cut by a wet knife to the size required. These strips or slices are then laid on trays of netted wire arranged in a frame or stand and dried till hard. Afterwards, to give them a bright polished appearance, they are dipped in clean cold water and again dried.

English glue is considered the best; it should be free from spots, clouds, waves, or cloudy lines.

Colour is not a reliable guide as to quality, but for cementing purposes the strongest is that made from hides of the larger and older animals, and is of a deep brown or semi-transparent claret colour; but this may, of course, be given artificially to other weak

kinds, such as those made from bones.

Glue loses strength every time it is remelted, therefore that newly melted is the strongest.

The hotter the glue is used the firmer it will hold. The addition of a little powdered chalk to glue strengthens it.

A considerable quantity comes from France, also from Italy, in bags, barrels, and cases.

Vegetable Glues and Sizings are obtained from the roots and underground stems of the palmetto, or other similar plants. The roots are cut up or disintegrated, and then submitted to about 300° F.; water is added, and the pectinous matter being thus extracted it is afterwards filtered, clarified, and concentrated to the jelly-like or solid density desired. It is with difficulty soluble in cold water, but possesses a considerable adhesive quality, and is much cheaper than animal glue, dextrine, etc.

An *Impermeable Glue.*—Soak ordinary glue in water until it softens, and remove it before it has lost its primitive form. After this dissolve it in linseed oil over a slow fire until it is brought to the consistency of a jelly. This glue may be used for joining any kind of material; and, in addition to superior strength and hardness, it will resist the action of water.

Bookbinders' Glue.—The best carpenters' or white glue, to which, after soaking and heating, one-twentieth its weight of glycerine is added.

Bank-note Glue, or *Mouth Glue*, is made by boiling 1lb. fine glue or gelatine in water till condensed to a viscous solution, then stirring in about ½lb. moist sugar, and finally running it through a net into moulds. Some add a little lemon juice. It is also made with 2 parts of dextrine, 2 of water, and 1 of spirit.

Waterproof Glue (sometimes called *Chinese Cement*) is made by boiling isinglass in milk, and is used to piece or repair glass, china, wood, etc. A cheaper sort of water-resisting glue is made by boiling 1lb. of common glue in 2 quarts of skimmed milk.

Special Firms.—Armour & Co., manufacturers, Chicago, U.S.A.; London address: 8 and 9 King Street, West Smithfield, E.C.; and C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Gluten Foods.—(See also *Fecula.*)—Gluten is a Latin word meaning glue or paste, and is the nitrogenous, gummy, or nutritious part of the flour of most grains, but especially of wheat and rye; hence our so-called Gluten Flours. It is found chiefly just inside the outer husk, and may easily be got at by washing meal or dough in a bag in water till all the white colour or starch be washed away, and what remains will be the sticky, tough, elastic, and glue-like substance called gluten.

Gluten is the base of "Turkish Delight," also of macaroni, vermicelli, and certain other pastes. Wheat gluten ferments very easily, but not so that of maize and rice.

It is very strengthening, and almost insoluble. Wheat contains 10 to 18 per cent., according to whether grown in a hot or cold country. English wheat contains 10 or 11 per cent. only, Algerian about 16 per cent. Rice contains very little.

Gluten is an important constituent in the blood, and it is that which causes blood to congeal. It is on the physical and chemical character of gluten that the baking quality of flour largely depends.

Gluten flour is mainly used as a substitute for ordinary flour in making bread, cakes, biscuits, etc., for persons suffering from diabetes, so that the conversion of starch into sugar in the human laboratory may be reduced as much as possible.

Gluten is the most nutritious part of wheat flour, being equal to that of flesh meat, but its preparations are not by any means so palatable as those made from ordinary flour. Hard wheat contains most, and the best qualities contain from 12 to 18 per cent., but it is chiefly obtained from the waste products in the manufacture of starch.

Gluten consists of three substances—vegetable *fibrin* (insoluble in boiling water), *mucin* (separates on cooling), and *glutin*. The purity or impurity of gluten flour is easily tested by washing the weighed flour in a muslin bag in clear water and then drying and re-weighing it. Any competent cook can make a good gluten flour by merely washing out the starchy matter from ordinary flour.

Gluten Bread is merely baked gluten, sometimes just in the state in which it is extracted from the meal, and sometimes mixed with a little bran, almonds, or some other flavouring to suit various palates. Gluten is often sold alone in a granulated form for soups, etc. *Bran Biscuits* are also supposed to be free, or nearly free, from amylaceous matter, but often contain far too much.

A great number of *bogus* gluten flours and starch-free foods are now being sold; but they are really frauds, and contain almost as much starch as does ordinary flour. One sample recently examined was three-fourths starch, yielding 0·715 gm. for each gramme of flour.

Occasionally ordinary "Seconds" flour is sold as gluten flour, at a correspondingly advanced price, and ordinary bread can be made from most of the brands on the market.

Glutiana.—See *Strichetti*.

Glycerine.—A bright, sweet, and pure syrup, without colour or smell, and technically described as the hydrate of the trivalent radical *glyceril*. It is found ready formed in some fats and oils, but is chiefly obtained by the saponification or decomposition of fats and oils, and especially as a by-product in the manufacture of candles and soap.

Besides being thus obtained spontaneously, it is also expressly prepared by a process for the purpose. Although identified by Scheele in 1789, and more distinctly still about the year 1831, by Guy Lussac and De Melly, it was not considered of any value, and used to be run into our rivers by soap and candle makers, along with soap lyes and other refuse, until 1844, when some of its excellent qualities were discovered by Mr. Thomas De la Rue.

Instead of being now wasted, it is carefully separated by several methods. One way is to treat the fats with steam at a very high temperature, or with water under a very high pressure. A third plan is to employ either sulphuric acid or lime, or caustic soda and water, each of these re-agents being able to transform the fats into fatty acids and glycerine.

Some 14,000 tons a year are thus recovered in soap manufacture, and 26,000 tons from stearin works, while the world's annual production of glycerine is calculated to average about 40,000 tons, and England now leads in the manufacture. Glycerines vary in specific gravity from 1·23 to 1·3, the standard of the British Pharmacopœia is about 1·25 at 60° F. Fine pale brown is usually about 1·25, and half-white 1·26; those of inferior quality have a disagreeable smell, and are sometimes coloured. When pure it is freely miscible with water and alcohol in all proportions, but with oil it only emulsifies, and does not perfectly blend. Excess of water renders the retailer liable for adulteration. Another adulterant is glucose syrup, as much as 45 per cent. having been recently discovered by analysts.

The purest glycerine is prepared by distillation; for although not volatile without decomposition, yet it passes over undecomposed in the vapour of water, and may be concentrated by evaporation. It is used in soap and paper-making, cosmetics, calico-printing, and perfumery. Wine merchants and brewers use it in wines and beers, to sweeten them, give body, and make them keep longer. In medicine it is used for dissolving drugs; as an emollient dressing for scalds, burns, etc.; and occasionally used internally, as with cod liver oil.

It is the best of all remedies for chapped hands, lips, nipples, etc. Diluted with water, it will generally allay itching from any cause. Infused in water for the toilet, it imparts a healthy clearness and a sensation of softness, smoothness, and coolness to the skin, and prevents chaps and other affections.

It is remarkable for not evaporating or turning rancid under any ordinary conditions. It can be charged easily with any kind of perfume, and is professedly

used in many varieties of soap, but is not alone a guarantee of excellence in soap, because some of the other ingredients are often as deleterious as the glycerine is beneficial, and for any evil consequences the glycerine should not be held responsible. Certain samples of glycerine have, however, recently been found which contained appreciable quantities of arsenic, hence it should always be selected and used with caution, or serious results may occur. When pure it is a drug endowed with certain active medical properties. It is used both as a medicine itself and as a vehicle for other medicines.

The Russians rub glycerine on their hands and faces as a protection from frost-bites. A little mixed with the water in a gas meter will help to keep it from freezing, and a little rubbed lightly over shop windows in frosty weather will prevent the opaque icy substance forming, which so often accumulates and obscures the glass. A little added to common ink gives it an excellent copying capacity.

Glycerine also when mixed with nitric and sulphuric acid forms that terrible but useful explosive known as *Nitro-Glycerine.*

Glycerine was first patented by Price's Candle Company, but now much distilled glycerine comes from Germany. As ordinarily sold retail it is, however, frequently diluted or adulterated to a degree which deprives it of the greater portion of its good qualities.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Glycerine Jelly. — Produced as follows:—

(1) Mix 4 ozs. of glycerine with 2½ ozs. soft soap, and stir in 4 or 5lbs. of almond oil, perfumed with 2½ drachms of thyme.

(2) (*Solid*) French gelatine, 120 gr.; glycerine, 1½ ozs.; water, ½ oz.; otto of rose, 1 drop.

(3) (*Carbolated*) 1 oz. isinglass, 16 ozs. glycerine, 3 ozs. water, 1 dram carbolic acid.

Glycerine Jujubes.—Usually prepared from the finest gum, sugar, etc., and distilled glycerine.

They are particularly useful in cases of sore throat, cold, etc. Apply to Jas. Epps & Co., Ltd., Homœo. Chemists, London.

Glycerine Soap (Transparent) may be made of lard with almond oil, palm oil, and nut oil, to which glycerine is added. It is sometimes made by melting very mild soap, and adding glycerine, free from lime, and sugar at the rate of 1lb. of each to 4 or 5lbs. of soap, but, as a matter of fact, the majority of so-called glycerine soaps contain no glycerine whatever.

They are generally perfumed with bergamot or geranium, mixed with a little oil of cassia and perhaps a little oil of bitter almonds. Some makers use a scent made up as follows for each cwt. of this soap:—6¾ ozs. rosemary oil, 3½ ozs. orange peel oil, and 1 oz. each of oils of cassia, thyme, and myrbane.

Glycose. — See *Glucose* and *Grape Sugar.*

Goa Powder. — As imported, this consists of lumps of a yellowish substance composed partly of powder and partly of pieces of wood. It is obtained from the plant *Andira araroba*, and its active principle is Chrysophanic acid; useful as a cure for ringworm and other skin diseases.

Godfrey's Cordial.—See *Soothing Syrups.*

Godiveau. — Meats dressed with ordinary veal stuffing are termed "au godiveau."

God-stone.—See *Sami-stone.*

Gogo Root.—A drug derived from *Entada scandens*, a leguminous plant growing in the Philippines. It occurs in pieces from 2 to 3 feet long and about 2 inches across.

Gola.—A name in Ladakh (Cashmere) for ball tea, a mixture of green and black, with rice-water to bind it.

Gold Leaf.—F. *Or en feuilles;* G. *Blattgold;* Sp. *Oro en hogas.*

Gold-leaf is classed as *singles*, *doubles*, or *trebles*, according to its thickness, and sold in books, each containing 25 pieces, the dimensions being three and a quarter inches square. They are placed between the paper leaves of a book, which are rubbed with red chalk to prevent the gold from adhering. The book should

be warmed before using, so as to make the leaves quite dry, and easy to detach one from another.

Gold-beating by hand is tolerably simple. The hammered metal, brass, or tin-plate, is laid on a massive anvil and beaten with hammers; to produce the greatest expansion of the metal, the hammer and anvil must both be convex; the convexity of the latter is of great importance. The sheet becomes so thin after a short time, that the further beating must be done with the sheets between animal skins. Great care must be taken that the skin is perfectly even and covers the whole sheet, which must be smaller, so as to give room for extension. The beater endeavours never to strike twice consecutively in the same place, and moves the skin after every blow. It requires considerable practice to ascertain when the body of the metal has the required thinness, as a fold will be produced by any doubling, and the separation of the leaves, sorting, etc., must be done very carefully between tissue paper, all draught being guarded against during the operation.

There are several different tints of gold-leaf varying from deep orange-red down to a pale silvery hue. Gold-leaf made in England is thicker and larger than that produced in the United States. Pale leaf gold is an alloy of silver and gold beaten into leaf. Dutch gold is copper-leaf coloured yellow by the fumes of molten zinc. It is much cheaper than gold-leaf, and useful for large surfaces, where it can be protected by varnish. Without such protection it becomes discoloured.

Golden Rod Tea.—See *Blue Mountain Tea.*

Golden Syrup—(See also *Treacle* and *Molasses.*)—Golden Syrup has only been known under this name since about 1860. It was first produced by a Mr. Munn, and is properly a refined treacle, obtained from cane sugar. It is much more agreeable to the taste, lighter in colour, and clearer than either treacle or molasses, and is, or should be made by re-boiling and filtering the liquid which drains from crystallised cane sugar in the refinery, after all the sugar that can be profitably extracted from the raw sugar has been separated. Such syrup, when genuine, still contains a small quantity of crystallisable sugar together with the uncrystallisable, also colouring matters and certain substances which give to the syrup its peculiarly agreeable flavour, but the exact nature of which is not known.

It is considered superior in flavour, and is sold at a higher price than either treacle or molasses. Imitations of Golden Syrup have, unfortunately, of late years been made up largely from glucose, flavoured with the refuse-molasses of a refinery, and, although very attractive *in appearance* for table use, they are altogether inferior to either golden syrup or common treacle. Some are adulterated with beet syrup or "inverted" beet sugar. They vary in sweetness according to manufacture, but the practice with refiners of adding glucose or starch syrup professedly "to prevent or retard granulation" has gone on until the name of "Golden Syrup" has almost degenerated into a synonym for mere glucose and water, 60, 70, 80, and even 90 per cent. being often found in it, and those who have so long been perpetuating the deception are now claiming the right to continue it. Of course there is scarcely any sweetening power or aroma in glucose. Some of these spurious syrups contain about 15 per cent. of cane sugar refuse, but with about 85 per cent. of glucose and water added. Other makes contain no *cane* syrup at all but merely inverted beet sugar and glucose, and are scarcely sweet. Retailers miss their own interests by giving their customers such stuff, and it is pitiful to see a useful commodity like genuine Golden Syrup driven out of existence by such artificial fabrications. We also fail to see why retailers should make themselves the scape-goats of either foreign beet growers or British refiners, or why they should be so ready to endorse the moves which these gentry suggest. The retailer's true friends are *his customers*, and he would do far better to exert himself in their behalf. He knows perfectly well when a customer asks for "golden syrup," or "syrup," that cane sugar syrup is meant, and not glucose and water. This glucose and water (glucose alone would be too

thick), costing about a half-penny per pound, is not there for the benefit of either the consumer or the grocer, but for the pocket of the manufacturer only. Why should retailers, by foisting it off, help manufacturers thus to cheat? If people want glucose and water, they will ask for it. But what shopkeeper quotes or tickets "Glucose!" How many more grocers will be fined and disgraced in the eyes of the public in order to enrich these manufacturers, who, labelling the stuff with specious jargon about the public good and prevention of crystallisation, etc., are merely seeking to evade the law and to deceive the poor? What grocer ever had complaints of cane syrup crystallising?

Syrups may possibly sometimes ferment, caused by too much exposure to the influence of vegetable germs, but not two grocers in a thousand ever had it go out of order, and any respectable firm would take it back without hesitation. The simple remedy for that fermentation is to replace such syrup in the cask, and burn a small quantity of sulphur in the cask, by placing a small flower pot with hot coals in the bung hole, and sprinkling a little powdered sulphur on them, taking care to cover the whole so as to keep the fumes in for a short time. This usually kills the germs, and the fermentation ceases. If not, heat the Syrup to about 180° F.

Dr. W. Blyth says that Golden Syrup should consist of about 39 per cent. of cane sugar, 33 per cent. of crude (inverted) sugar, 2·8 per cent. of extras and colouring matter, 2·5 per cent. of salts, and 22·7 per cent. of water.

A few firms, and a few only, now sell the genuine article, but amongst these are :—Graham Brothers & Hay (refiners of Cane Syrup), 16 Stanley Street, Liverpool; and The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Goldwater, or **Dantzig Water.**—F. *Eau de Vie de Dantzig*; It. *Acqua d'Oro.*

A light liquor or cordial, very sweet and strong, made in Dantzig. Originally it was nothing else but brandy, in which had been macerated rosemary flowers, cinnamon, aniseed, grains of paradise, cloves, cubebs, liquorice, etc., to give it taste and colour; afterwards minute portions of gold leaf were added.

In the mind of the middle ages gold was held to be the remedy for every evil. It was put in drinks, victuals, pills, elixirs, tinctures, etc., and even in baths, to please the public fancy, and Dantzig water or gold water survives a host of similar compositions.

A quantity is now made in France and elsewhere.

Gombo. — See *Gumbo.*

Gommer, or **Amel Wheat.**—Ger. *Dial.*

A kind of black corn, *Triticum amyleum* (Amel wheat), husked and prepared for food in Darmstadt, where it is very popular as an ingredient for soups.

Gonyonha, or **Congonha.**—See *Matè Tea.*

Goor.—See *Gur.*

Gooseberries (gorse or prickleberries). — Da. *Slikklesbær*; Du. *Kruisbes*; F. *Groseilles à maquereau*; Ger. *Stachelbeeren*; It. *Uvas Spinas*; Port. *Uvas espims*; Sp. *Grosellas*; Rus. *Kryzhovnik*; Sw. *Stickelbär*; W. *Grwysen.*

A familiar fruit of the thorny little shrub, *Ribes gros sularia,* indigenous to the North of Europe and Asia, but most popular in England. They do not appear to have been cultivated before the 17th century, and a hundred years ago did not attain half the size they are now grown.

They ripen as far north as Norway, but do not thrive in warm climates. Large quantities are grown in Meath, Ireland. The earliest berries come from Havre, Honfleur, and other French ports, also Holland.

Red gooseberries contain the most acid, but some are very sweet. White varieties vary much in quality, and green sorts differ materially; some have thick skins and poor pulp, others are thin-skinned, with sweet or even rich juice; and yellow varieties range

from the lowest to the highest in flavour.

Gooseberries, both wholesome and pleasant, may be eaten either raw (when ripe) or cooked, when they make excellent jam, jelly, wine, and vinegar; but the unripe fruit makes the best tarts and puddings, either when fresh gathered or bottled.

The French name for this fruit arose from a custom, now very rare in that country, of placing a few of the ripe berries around mackerel when roasting it in the oven.

Gooseberry fool is a corruption of gooseberry *foule*—that is, milled or compressed gooseberries.

Bottled gooseberries.—Green gooseberries are the leading fruit used for bottling (see *Bottled fruits*), and the most suitable berries for the purpose are those known as "Crown Bobs" and "Warringtons," preferably the latter. The fruit for this purpose should be gathered when full grown, but still hard and green—not in any way approaching ripeness—and bottled at once, before they sweat or become flabby, and lose one of their best qualities—namely, *crispness*.

The filler should use a small round stick, so as to pack the berries tight, but without bruising them, for they shrink afterwards, and if filled loosely the bottles look only three-parts full.

Bottled gooseberries, closely corked and sealed or capsuled, should keep good three or four years, and improve in flavour.

Other excellent varieties are the *Lancashire Lad*, *Keepsake*, *Whitesmith*, and *Whinham's Industry*. (See also *Cape Gooseberries*.)

On fruit farms green gooseberries are usually gathered by women and boys at the rate of about 1d. per stone or 2d. per half-sieve, according to crop. For *London* markets the baskets contain 28lbs. of fruit. The sides are lined, the paper being sufficient to allow of the two sheets lying over one another when turned down to screen the fruit and keep it clean.

Ripe gooseberries for market must only just have assumed their colour when gathered or they will split open and spoil.

Gooseberry Jam.—(See also *Jams, Preserves*, etc.)—Any sort of gooseberry will make a good jam, but the best for the purpose are the green "Cockspur," the red "Ironmonger," and the rough red "Warrington" gooseberry.

First remove the blossoms and stems of the berries and throw out all damaged ones, then put 14 ozs. sugar to every pound of fruit into a pan, with a pint of cold water; place it on the fire, and commence to stir until the sugar melts; it may then be stirred only occasionally until it gets nearly ready, when it will require stirring continually until finished. As it begins to boil thick take out a little on the bottom of a cold plate. Stand it in a cool place for one or two minutes; if it congeals it is done, if not, boil a little longer and try again. The moment you see it congeal on the plate lift the pan off the fire, and commence to pot the jam.

A learner, when trying jam by this old method, should lift the pan off the fire until he sees whether it sets on the plate, as the bulk may be overdone or burnt while the sample is cooling.

The best method to test jam is by dipping the spoon or spaddle into the boiling liquid, and holding it over the pan while boiling; if the jam is done it will drop off in webs, if not it will run off thin. Considerable practice is required to test jam in this way; but when acquired it saves time, and the consistency is more uniform.

Goose-breasts. } Smoked Pome-
Goose-legs. } rian goosebreasts and legs are saleable commodities in high-class neighbourhoods. They possess a fine flavour, and are done up in skins.

Gorgonzola Cheese (or *Stracchino of Gorgonzola*.—A very fine and rich Italian kind. Average weight 16lbs. Composition: Water 43·56, casein and albumen 24·17, fat 27·95, ash 4·32. It is very like ripe Stilton in quality, though differing from it in shape and size. It is said to be made of two

curds, from rather poor milk and without pressure. It ripens in about 18 weeks, and is cured in a draughty cellar. The interior of this cheese grows a green mould (*Penicellum glaucum*), and is usually skewered to promote its growth.

It is only during the latter half of the present century that this cheese has come into repute. Its manufacture is said to have originated in the following manner: As soon as the cold weather of the autumn approaches, the cows have to leave the Alpine pastures for those in the plains, and the milk they gave during the journey could not be made into cheese in the ordinary way, but while still warm was curdled and hung in cloths from the cart of the herdsman, each successive milking being added, so that at the end of the journey the cheese so produced was salted and called *stracchino* ("strache" meaning, in the Milanese dialect, tired cows). As the first halt in the plains was usually made at Gorgonzola the cheese got the name of *Stracchino of Gorgonzola.*

In the course of time, and in order to meet the increased demand for this cheese, it became an article of special production instead of a makeshift as at first, and its manufacture has now extended not only all over Lombardy, but even to the district of the Lomellina, in Piedmont.

The rennet is added to the milk as soon as it is drawn from the cow, enough being used to produce coagulation in half-an-hour. The curd is then broken up; that of evening milk is ladled into cheese cloths of about three gallons each, and hung on pegs to drain until morning. In the morning the milk is similarly treated, except that the curd is drained for a quarter of an hour only. The two curds are then filled into wooden hoops, inside each of which a cheese cloth has been placed to form the rind. Care is taken to keep the warm curd of that morning's milk outside, so that it will unite and form a smooth crust. The cold curd of the previous evening's milk is placed in the centre, and from this arrangement arises the peculiarity of Gorgonzola cheese. The two curds of morning and evening milk, warm and cold, never thoroughly amalgamate, and it is in the cracks and crannies thus left that the blue mould grows as the cheese ripens. The story that the blue mould of Gorgonzola is produced by inserting copper wire and instruments into the cheese is absolutely untrue. During the first day the cheese is turned three or four times, and then daily for three or four days, when salting begins. When to begin and leave off salting is a matter in which the experience and skill of the maker are most displayed. After salting is completed the cheese is taken to the drying-room and kept there for several days until bright pink spots begin to show on the crust. Four or five months in the curing cellar, and turning every alternate day, complete the ripening, when the cheese is ready for the market. Inside these cheeses, and especially those made during the journey down the mountains, are found the greenish marks vulgarly termed "erborine."

After the manufacture of the Gorgonzola is over for the season—say, November—another quality of rich cheese, called *Crescenza*, is made in the provinces of Milan and Pavia. It is soft and slightly acid in flavour, and has lately come into importance by reason of the Parcel Post system.

These cheeses are known as the *Stracchini of Milan.*

The best qualities grow a peculiar red fungus on the outside, and to imitate this many are covered with brick-dust and flour. Gorgonzola cheese has a pretty large sale, but it is considered very indigestible, and, like Stilton, it is used more as a condiment than a food. Much is now made in England and elsewhere to imitate the genuine.

They keep best if left in the ordinary packing until wanted for use.

Although not properly soft cheese, Gorgonzola should be treated as such on account of its rather perishable nature. Being very brittle and easily

broken, great care should be taken in removing them from packages, and they should never be piled more than two high or the weight will crack the bottom one. They should be kept cool, but never in a draught, nor should they be allowed to freeze, and they should be cut with a wire.

Gouber Nuts.—See *Ground Nuts.*

Gouda Cheese.— (See also *Dutch Cheese.*)—An excellent kind of Dutch cheese, round and flattish, shape of a curling stone, and is said to be the best kind made in Holland.

It is salty, but not so much so as Edam. It is both red and pale coloured, and classified as "good useful," "fine," and "finest." It is supposed to owe its pungent taste to the practice adopted in Holland of curdling the milk with hydrochloric or muriatic acid, instead of with rennet. This also preserves it from *mites.*

Factory Goudas are usually made of skimmed milk in Friesland, and in both England and elsewhere they are closely imitated. (See also *Derbyshire Goudas.*)

Goundry's Consolidated Tea.—Simply the ordinary tea of commerce pressed into blocks by hydraulic pressure. Tea, in its ordinary state as sold, contains an average of 8 per cent. of water, and in making the consolidated tea almost 6 per cent. of water is pressed out. This would at first sight seem an advantage, since one would expect more tea to be left; the fact is, however, that the gain is quite counter-balanced by the loss of the extractive portion of the tea which is forced out along with the 6 per cent. of water.

Gourds.— Sp. *Calvasinos*, or *Calabasas.*

A very large family of cultivated plants and their various fruits pass under this name, such as pumpkins, vegetable marrows, squashes, melons, cucumbers (which see). The "gourd" mentioned in the Book of Jonah was probably a species of *Ricinus.* The word "gourd" is also applied to the dried and hollowed skins, cases, or shells of these fruits, which are used as bottles, dippers, funnels, and small dishes. The whole of the gourds are very rapid growing annuals, with broad leaves, yellow flowers, and long rough trailing stems. They are natives of warm climates, but many kinds grow well in Britain. One of the best is the *Great Gourd* (*Curcubita maxima*), of which the green-fruited *Spanish Gourd* is a variety. The largest of all is the *Great Yellow Gourd* (*F. Potiron*), and grows up to 200lbs. weight, and takes a globular form some 8 feet in circumference. *The Warted Gourd* (*C. verruno*), a very hard skinned kind covered with large warts, and *the Musk Gourd* (*C. moschata*) are less hardy than the others; also the *Orange Gourd* (*C. aurantia*). Gourd leaves and young shoots are often used as a substitute for spinach. Bitterness of taste in either fruit or leaves betrays the presence of colocynthus, and such should be discarded. Ripe gourds will keep good a long time in a cool, dry, well-ventilated place, and may be cut and used at different times as required.

At Nice, in France, there is a Gourd Festival held yearly in the Square of the monastery of Cimiez, where gourds of all sorts and sizes may be seen painted and decorated in profusion.

Gourou Nuts.—See *Kola Nuts.*

Grafting Wax. — Subjoined is a valuable formula for making liquid grafting wax. It was kept a secret, and sold at a high price for a long time. All who have used it speak of it as being the best preparation for covering wounds in trees which has ever been discovered.

Melt 1lb. of common resin over a gentle fire, add 1 oz. of beef-tallow, and stir well; cool a little, and mix with it a tablespoonful of spirits of turpentine, and then add 7 ozs. of 95 per cent. alcohol. The alcohol will cool it so rapidly that it will be necessary to put it again on the fire, stirring it constantly and with the utmost care to prevent the alcohol from getting inflamed. To avoid this the best way is to remove from the fire when the lump

commences to melt, and stir and repeat until the whole is a homogenous mass, similar to honey. It should be put on with a painter's brush. After a few days' exposure to the atmosphere in a thin coat it becomes as hard as stone and impervious to water and air.

Grained Soaps. — Also known as *Boiled Soaps*. These terms are used to define soaps that have been remelted and worked afresh for making fine toilet or medicated soaps.

Grains.—See *Brewer's Grains*.

Grains of Paradise.—(See *Cardamoms.*)—Also known as *Guinea Pepper*, *Guinea Grains*, *Melegueta Pepper*, etc. The seeds, not of a pepperwort, but of the *Amomum Granum Paradisi*, and best known by their modern name "*Amomi*," a species of Cardamom, which are very hot, acrid, and pungent, and slightly aromatic. They are small and angular in shape, and of bright black colour outside, but perfectly white inside. Imported in casks, etc., from the coast of Guinea, East Indies, and Africa, where they are very popular with the natives for flavouring foods. In ancient times these "Grains de Parys" were used as a spice in English cookery, but are now chiefly used here for making stimulative kinds of cattle medicines or powders. They are said to be also frequently employed for giving a false body to beer, vinegar, fermented beverages, and spirituous liquors, such as wines and spirits—especially to gin—and increasing thirst. Penalty for so using them is £200, or for vending them to brewers £500, but this has been commonly evaded by the chemist selling them to the brewer's or publican's friend.

The capsules or dry berries of *Capsicum fruitescens* are often erroneously sold, even by druggists, under the name of "Guinea Pepper."

Gram.—See *Chick Peas*.

Granadilla, or **Grenadillo.** — The fruit of the Passion flower (*Passiflora quadrangularis*), a kind of pomegranate. They are egg-shaped fruits, and vary in size from gooseberries to turnips. They are used as a dessert in many tropical countries. Sometimes made into conserves, jellies, etc., and to some palates the flavour is very agreeable and the juice refreshing.

The name is also used for the edible fruit of other allied species of plants.

One variety of the plant is grown in our English gardens for the sake of the flower. In Madeira there are two varieties, the larger being a golden-coloured, oval-shaped fruit, and the smaller when ripe of a deep purple-brown tint. The taste and fancy for this fruit is not very keen at first, and the relish for it, like that of many other tropical products, has to be acquired.

Granilla.—An inferior quality of cochineal, prepared from the half-grown or smaller particles and dust of a lesser species of the cochineal insect. It includes the garblings or siftings got in preparing the better kind, and only yields about a third of the colouring matter of the true cochineal.

Mostly imported from the Canary Islands, but a Mexican product is often substituted or used as an adulteration for both cochineal and granilla. It consists chiefly of a species of *lady-bird*, which are merely parasites of the real cochineal insect (*Grana sylvestra*). Wholesale, 3d. or 4d. per lb.

Granulated Sugar. — Sugar which has in manufacture been stirred during the crystallisation of the concentrated syrup, and thus formed into small disintegrated crystals or grains, instead of being allowed to compact into a mass or lump as in loaf sugar.

Granuline. — A German cleansing and washing preparation, consisting principally of carbonate soda, soda soap, with traces of salt and sulphate of soda.

It is a whitish-yellow brittle substance, somewhat fatty to the touch, and having a slight bergamot odour. It is readily soluble in hot and cold water, forming a fluid which has a strong alkaline reaction; 100 parts of granuline contain 87·5 per cent. of soap and 12·5 per cent. of carbonate soda.

Grape Fruit.—See *Forbidden Fruit*.

Grapes.—Da. *Druer*; Du. *Druiven*; F. *Raisins*; G. *Trauben*; It. *Grappoli*,

Grappi; Per. *Ungor;* Port. and Sp. *Uvas;* Rus. *Vinoghrady;* Sw. *Drufoa;* W. *Grawnwin.*

The native country of the grape vine cannot be determined satisfactorily. It is of prehistoric antiquity. It appears indigenous to many parts of the world, but the origin of the cultivated fruit is unknown. Grapes were cultivated and wine made in Egypt 4000 B.C., and we read that Noah, 2348 B.C., "planted a vineyard."

The men sent by Moses in 1490 B.C. to search the land of Canaan "came into the brook (or valley) of Eshcol, and cut down from thence a branch with one cluster of grapes, and they bore it between two upon a staff."

The Phœnicians first introduced the vine into Europe—Greece and Italy, whence it spread into France and other parts of the Continent.

England is considered too cold and damp for out-door grape culture, although between the 11th and the 14th centuries they were grown somewhat extensively in Essex, Isle of Ely, Lincolnshire, Cambridgeshire, Bedfordshire, Hants, Surrey, Derbyshire, and Gloucestershire. The latter was the chief wine district of England.

It would appear that vineyards were fairly successful as long as they were connected with the abbeys and priories of those times, and because many of their inmates were foreigners understanding vine culture.

These well-known, pulpy, and luscious fruits are produced in clusters from different species of the vine in all warm climates, but in Europe they are principally grown in France, Italy, Spain, Portugal, Germany, and adjacent islands. They are of the genus *Vitis vinifera*, and there are over 1,500 varieties, mostly grown for making into wine, although many kinds are used for eating fresh, or dried and made into raisins.

It is estimated that there are about 20 million acres of land in the world under vineyards, and that of this total France owns nearly one-third. In France and Germany the vines are cropped down as small bushes and tied to stakes, but in Italy they are trained over elm and poplar trees, running from branch to branch. Large quantities are now coming to English markets from Cape Colony. They arrive in cases holding about 18lbs. The white or green varieties closely resemble "Almerias," but are much superior in flavour. Fresh green grapes in vast quantities are imported in small barrels about 50lbs. each from Malaga and other parts of Spain. *Almeria grapes.*—About 300,000 barrels of these favourite dessert fruits are exported yearly from the port of Almeria, in the South of Spain, one half of which come to England. The early-coloured varieties, known as "Castiza," "Uva de Casta," "Rosadas," and "Imperiales" begin to arrive at the ports of Liverpool, London, etc., at the latter end of September, and the others continue to pour in until December. The prices vary from 10/- to 40/- a barrel, and the total crop averages about 750,000 barrels. The *phyloxera vastatrix* has done much damage, but the cultivation of new vines is extending in Tabernas, Nijar, Beija, and Ohanies. The chief shipping variety is there called "*Uva de embarque.*" These fruits come in tubs, called half-barrels, packed with cork-dust.

As many as 30,000 and 50,000 barrels of grapes reach England weekly in the season, which runs, say, up to Christmas. Each half-barrel holds about 48lbs. of fruit. Those brands which are known to be keepers are bought by market packers principally; these are men who buy and pack goods to the provinces. They swarm around Covent Garden and other public fruit markets, and rent large cellars in which the barrels of grapes are stored, to be sold later on by the barrel, or turned out and cleaned with a pair of bellows and a clean black lead brush, by being put up in what are termed dozens, that is, shallow boxes holding 12lbs. of fruit each. The profits on their sale after they have been stored two or three months are very large, and, in fact, independencies have been made by men experienced in the keeping qualities of the brands that are sent to Pudding Lane and

other centres for sale by the fruit brokers. There will thus be greater competition than ever in the future between the late Almerias and the Cape grapes in the early spring months of the year.

Denia grapes are of earlier growth by a few weeks than the true white Almerias, and come first into market; then follow the tinted growths. Barrels weigh about 25lbs.; Malaga half barrels, 14lbs.; Lisbon half boxes, 50 to 60lbs. The grapes raised in Greece, the Ionian Islands, and Asia Minor are mostly dried into currants and raisins. (See *Currants, Sultana Raisins*, etc.) The best table or dessert grapes are not the best wine grapes, nor *vice versâ*. The famous Thomery and Chasselas growths, for example, with their thick skins, crisp pulp, and abundance of sugar, melting like a bonbon, are of delicious flavour, but are not at all wine grapes, because they yield very little juice; yet they fetch 5/- to 6/- per lb. in the Paris markets, whence they are distributed all over Europe.

Unripe grapes and grapes from certain climates contain much malic acid. Vendée grapes have been found to contain as much as 15 grammes of *tartro-malate* per litre. In certain white wines the malic acid sometimes exceeds the total tartaric acid.

The *Black Hamburgh* is the popular grape of Britain, and of the *white* grapes (so-called) the *muscat*, of Alexandria, is considered the choicest and most valuable. English hot-house grapes, produced with all the advantages of modern structures and modes of heating, combined with skill in cultivation, surpass all others in size of bunch, berry, and high quality.

Finest English hot-house muscat grapes fetch highest prices, varying from 2/- to 10/- per lb. according to season. *Jersey muscats* come next in value; Belgian hot-house only bring half the price of English. The above are to be had wholesale from green fruit merchants in baskets of 6 to 12lbs. each, and in neighbourhoods where people have money, they sell well.

Ripe hot-house grapes keep best when cut with a few inches of the wood attached, and before the grapes are damaged by wet or cold. If the choicer bunches are hung up with the lower end of the shoot in a bottle of clear rain-water, in an inclined position, they will keep quite good and fresh from the end of September to January or February. The temperature may vary from 35 to 50°, but they must not be exposed to frost. They should be looked after almost daily, and any decayed berries should be removed. A little charcoal should be put in the water to keep it sweet. The atmosphere of the room or cupboard should be fresh and dry, but if too dry the grapes will shrivel.

Another good way to keep grapes fresh and sound is to pack them in plenty of peat-dust in wooden boxes and store in a cool, even temperature.

Grape-Seed Oil. — Used in the Levant for purposes of illumination. The extraction is principally effected at Modena. Thirty-three pounds of seeds yield about 13 quarts of oil (or about 18 per cent.). The colour is yellow, and the oil loses about 25 per cent. in purification. The seeds of white grapes yield less oil than those of the dark variety, and young vines are said to be richer in oil than older ones. As to the French varieties the Rossillar, Aube, and Hernault seeds yield 2 per cent. more than Bordeaux seeds. The oil resembles castor-oil, and on treatment with sulphuric acid yields a Turkey-red dye.

Grape Sugar.—(See also *Dextrase, Glucose*, etc.)—This is the name given to solidified glucose, and may be produced from the same substances as liquid glucose, its formula being $C_{12}H_{14}O_{14}$. It does not exist (as its name would imply) in the juice of grapes, but is formed therefrom in small incrustations on raisins, etc. It is this which gives honey its sweetness, but it has only about one-third the sweetening power of cane sugar.

The methods pursued in nearly all the refineries are, however, now iden-

tical. Wet starch obtained from potatoes, or Indian corn, etc., is boiled in so much sulphuric acid and water. This acid makes part of the oxygen and hydrogen in the water unite with the carbon in the starch, and turns it sweet, after which the acid is taken out with chalk.

Chalk is carbonate of lime (carbonic acid and lime), and the sulphuric acid at once combines with the lime and frees the carbonic acid gas, which at once passes off in the air as a gas, while the sulphuric acid and the lime form into sulphate of lime or gypsum, and is easily removed, leaving the sweet syrup, which is then boiled down or evaporated until the sugar crystallises.

The production of grape sugar and liquid glucose is now mostly carried on in America, where maize is most plentiful and cheap, but large quantities are also made in Germany from potatoes, which are specially grown for the purpose over a great extent of land in certain districts. Grape sugar or solid glucose is usually imported in 1 cwt. cases, but most users prefer the liquid glucose.

The grade known as *Chicago Chips* comes in bags.

Graphite, or Plumbago. — The mineral from which "Black Lead" is prepared. (See *Black Lead.*)

Grate Black. — See "*Komo*" *Enamel.*

Gravy Colouring Salt. — See *Browning.*

Grease-proof Paper.—See "*Vegetable Parchment*" and "*Waxed Paper.*"

Greaves, or Graves.—The sediment from melted tallow, consisting chiefly of animal membrane mixed with fat. Usually made up into cakes, and prepared as a coarse food for dogs, etc.

Grecian Wines. — The calcareous soil throughout nearly the whole of Greece is highly favourable to the growth of the vine, but the productions are variously described. Even when good, sound, and firm-bodied, they have generally a resinous or turpentine flavour. It is the custom there, after washing out the wine presses, tubs, etc., to rub them with resin obtained from certain pine trees, that of the dwarf pine (a mere bush) being considered the most suitable. The variety of climates and exposures which the elevated ground of these islands presents serves to diversify, to an infinite degree, the qualities of the wines obtained; but the vinification seems to be more or less imperfect. *Monthymet* is a very fair mild quality. The "Nectar" of *Morta* is somewhat bitter and astringent. *St. Elie* and *Calliste* are white, and known as the *Wines of Night.* The *Verdea* of Zante, also a white wine, possesses the flavour of Madeira.

The best known kinds are those of Candia, Cyprus, Lesbos, Malmesyne, Malmsey, Mount Hymet, Naxos, St. Elie, Scio, Tenedos, Thera (Santorin), Visanto, and Zante.

A new industry has sprung up in Greece of late years, viz., the making of wine from the dried fruit by a process of maceration; raisins and currants were largely shipped to Marseilles for that purpose, where they pay a duty of 25 fr. per 100 kilos. Wine so made abroad was until lately only subject to 70c. per hectolitre. Now, as 100 kilos. represent about 3 hectolitres of wine of 10 degrees, it results that 100 kilos of dried fruit paying 25 fr. in reality only pay 21 fr. as wine. In France wine so made cost about 75 fr. for 3 hectolitres, and to the foreign producer only 68 fr., leaving a margin of 7 fr. in favour of the latter. This induced many houses both in Greece and elsewhere to embark in the enterprise. Unfortunately France has raised her tariff. An attempt was made to induce the Grecian Government to modify its law in regard to dried fruit reserved for the distilleries, which it is calculated only absorb 8,000 tons, whereas it was stated there were 18,000 to 20,000 in store. The measure, however, met with opposition, from the fear that it would act prejudicially to the export of natural wines. The making of wine in France from dried fruit was

only an expedient, but it now seems to have taken some hold in the country. The process it undergoes renders this wine a poorer quality, requiring to be rectified in various ways.

Green Corn.—See *Canned Corn.*

Green Fruits, Vegetables, etc.—*Green Fruits* comprise almonds, apples, apricots, bananas, chestnuts, dates, "forbidden"-fruits, grapes, lemons, melons, nuts, onions, oranges, pears, peaches, pineapples, plums, pomegranates, pomeloes, shaddocks, tomatoes, walnuts, etc., all of which are referred to under their own headings, while rhubarb, gooseberries, strawberries, raspberries, red, black, and white currants, etc. are classified as *Soft Fruits.*

Formerly most of these fruits arrived in our markets in somewhat regular sequence, but railways, steamboats, telegrams, cablegrams, and telephones have completely revolutionised this trade, and having now the gardens of the whole world opened to us, the fruits and vegetables of not only Europe, but also of the tropics and the antipodes are, with the aid of ice, arriving from somewhere all the year round.

Fresh fruits, such as apples, peaches, apricots, etc., come by steamer from South Africa to London, and are usually offered on the markets within twenty-one days of being picked in the Cape orchards. In January cauliflowers have long arrived from Italy, but they are hard, too sweet, and only of poor quality. Other vegetables and fruits are now coming from there in large well-ventilated carriages specially constructed by the Belgian State Railway Administration, and reach London by direct through service *viâ* Chiasso, Bale, Brussels, Ostend, and Tilbury. Finer cauliflowers soon arrive from Brittany and Anjou, where this vegetable is cultivated on a large scale. Artichokes come from Angers, Brest, Bouches du Rhone, and Laon. The earliest asparagus makes its appearance in March from Tours, Angers, Orleans, and Avignon. First potatoes come in January and February from Canary, then in March and April from Algeria and Malta, the next from Italy, and afterwards from Jersey and South of France; German Reds in October. The greater part of the "*Primeurs*," or French early vegetables, salads, and fruits are forwarded by merchants who make it their special business to collect and pack them and pay the Customs duties in Paris.

A very important matter in ordering fruit from the grower or wholesaler is to have it clearly settled in what kind of packages it is to be delivered.

The principal fruit and vegetable-growing counties in England are Bedford, Cambridge, Chester, Cornwall, Devon, Essex, Gloucester, Hants, Hereford, Herts, Kent, Lincoln, Middlesex, Norfolk, Northampton, Salop, Somerset, Suffolk, Surrey, Sussex, and Worcester. The fruit-growing centres in the south are Broxbourne, Sawbridgeworth, Swanley, Brighton, and Worthing. Large quantities also come from Guernsey and Jersey, especially "English tomatoes" in 12lb. baskets (the baskets being all made in France). Probably no other products fluctuate in value so much as fresh fruits. They must always be rushed into the markets when ripe, and nothing rises or falls more rapidly. Twelve hours of "glut" usually means a dead loss to growers, the prices realised often being insufficient to pay railway carriage and "handling."

But a more serious matter to "senders" is the loose and dishonest way sale returns are made out by many commission salesmen. Excessive and fictitious charges for carting, warehousing, porterage, and other incidentals are sadly frequent in some quarters, and the "prices" returned are often wilfully understated, and not infrequently goods are disposed of to the salesman's friends at half market value.

The only check the consigner seems to have is to divide his fruit into two or three lots and note the prices each salesman returns.

The lack of rules regarding uniformity in weights or measures for

fruits is another undoubted drawback to legitimate business in the wholesale fruit trade. "*Reputed*" weights and measures should be abolished and standards enforced.

Much depends on how fresh fruits are packed; as a rule they should be packed stalks upward. The good and the inferior should never be mixed, but each quality graded and packed separately and honestly, not the best on top and inferior below. Potatoes are usually sorted, why not fruits? The fruit should only be gathered when perfectly dry, should not be bruised by careless handling, nor the stalks broken off. The softer fruits are often spoilt in transit either through over-ripeness or loose packing; the shaking to or fro soon bruises and renders them almost unsaleable. The packages as well as the packing should also be perfectly dry. The sides of the baskets should be lined with clean paper, called "fruit paper," costing 1/6 to 3/- per ream for whitey-brown, and about 3/6 for blue paper. It should stand over the sides sufficiently for folding over the fruit. To protect the fruit from the weight of other baskets and hold it firm some clean straw, long grass, pea-haulm, coarse hay, or wood-wool should be placed over the paper and the whole secured by two sticks—a hazel about as thick as the thumb, split lengthwise, pointed at the ends, and stuck into the upper rounds of the basket. Small boxes are, however, to be preferred before baskets. Fresh grapes should be packed in long shallow boxes with a couple of strong wires stretched lengthways on which to suspend the bunches without rubbing off the bloom.

Strawberries, raspberries, gooseberries, cherries, etc., and other soft fruits for the retail trade are best packed in punnets, and these then fitted into cases made to hold a certain number, but for factory and boiling purposes they are usually packed in 12lb. baskets.

Dessert apples, pears, tomatoes, etc., may be most conveniently packed in a similar manner as grapes. Peaches, apricots, nectarines, and best plums should each be wrapped in soft tissue paper and arranged in single layers with cotton wool, so as not to crush into each other; also in small strong boxes that will not bend.

Cucumbers travel best wrapped in tissue paper and stood upright in deep boxes, instead of being laid flat and piled on top of each other.

The best storage for fruits is a building with double walls, doors, and windows, with a thatched roof ceiled with boards and lined on the top with roofing felt to keep it air-tight, sunk into the ground about 3 feet, with the excavated earth piled against the walls outside to near the edge of the roof, so as to keep frost and outer heat away, and preserve the inner temperature at 35 to 50° Fahr. all the year round without fire.

Apples are handiest stored in flat open bushel boxes, which may be piled on top of each other to economise space.

Cold weather generally comes so suddenly that few are prepared for it. Every year shopkeepers lose thousands of pounds' worth of goods because their cellars and storehouses are not frostproof. They intended, of course, to have everything fixed and put in proper order, but the frost caught them unawares, and their goods were spoiled on account of their procrastination. It is better to put up your storm windows and get your heating apparatus in good shape. There are cellar doors that need repairing; air-holes in the partitions that should be stopped up; exposed walls that should be banked up with straw. All grocers and general fruiterers know these things very well, but they put off day to day what should be done at once, and the sudden and unexpected coming of a cold snap catches them.

Canned goods, vegetables, fruits—in fact, groceries of various kinds, are ruined in quality and flavour by freezing; some are utterly spoiled, and become a total loss. All of this might be avoided by a little precaution and care.

Business may be brisk, but there is plenty of time to look your premises carefully over and see if everything is all right. It will not require a great amount of labour or expense to make everything snug and tight and ready to fight the frost. Attend to this matter early, and it may save you much money.

Experiments are now being made in preserving fresh fruits in borax. It has been found perfectly successful with cherries, and is also being tried with vegetables. It appears that the borax, though costly, can be used over and over again, so that economy is to be secured in a double fashion.

English fruit raising is not likely to develop much, because of climate, land tenure, and uncertainty of crops; but there are few trades in which better profits can be made than in fruits when properly handled. Wholesalers often secure 20 to 40 per cent., and retailers would do much better to buy fresh goods under the hammer in the first market—such as Covent Garden and other centres—instead of stale stuff at private warehouses.

Retailers of fruits, vegetables, and flowers will also do well to see the show stands, trays, dishes, and arches cleverly designed, and supplied at all prices, by Parnall & Sons, Narrow Wine Street, Bristol. A good display is one of the chief factors for success.

Special Fruit Firms.—M. & W. Jones, Villa Nova de Gaya, Portugal; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; Draper & Son, Covent Garden.

Subjoined is a list of the chief market days for fresh fruits, vegetables, etc., in the leading centres, also of the weights, measures, and packages employed. The foreign packages are, of course, the same in all towns.

Aberdeen.—Tuesdays and Fridays.

Birmingham (Smithfield).—Wednesdays and Saturdays.

Apples, cherries, currants, and gooseberries are sold in packages of 63lbs.; damsons, green walnuts, pears, plums, etc., per 72lbs.; other ripe fruits, in sieves, etc., per 12lbs.; parsley, spinach, turnip tops, etc., per 20lbs.; artichokes, beets, and potatoes, per 80lbs.; peas, beans, and sprouts, per 40lbs.; carrots, parsnips, and turnips, per 56lbs.

Cardiff. — Tuesdays, Thursdays, Fridays, and Saturdays.

Edinburgh and Leith.—Tuesdays, Thursdays, and Saturdays.

Glasgow. — Tuesdays, Wednesdays, Thursdays, and Fridays.

Fruit and Vegetables are not sold by measure in Glasgow and the West of Scotland, and Imperial measures are used only rarely by retailers. Everything goes by weight. The old-fashioned sleek, or West of Scotland bushel, is used, but it is represented by a fixed weight; thus a sleek of apples is 40lbs., pears 50lbs., and plums 60lbs. Generally sales are at per cwt. or per package.

Gloucester.—Mondays and Wednesdays.

Hull is the central market for fruit, plants, and flowers on the East Coast. Sale days, Mondays and Thursdays.

The following are the ordinary packages:—Belgian apples in barrels of 60 kilos; Belgian cherries per molly 10lbs., large molly 15lbs.; French apricots per pad; German bilberries in chip baskets of 4 kilos; German *cherries* per half sieve of 8 kilos; German apples in barrels of 50 kilos; Dutch black currants. per basket of 7 kilos; Dutch red currants per basket of 6 kilos; Dutch pears per half mud of 15 kilos; Dutch cherries per basket of 6 kilos; Spanish tomatoes in 8lb. boxes.

Leicester.—Wednesdays, Fridays, and Saturdays.

Liverpool.—Market Days, Cazneau Street and Queen's Square: Tuesdays, Wednesdays, Thursdays, and Saturdays.

Cherries.—English: Half bushel, 24lbs. net; half pot, 32lbs. net; pot, 63lbs. net. French: Pads. 14/16lbs. net; sieves, 14/16lbs. net. German: Baskets, 15/18lbs. net.

Plums, Damsons, Greengages, etc.—English: Half bushels, 28lbs. net; half pots, 36lbs. net; pots 72lbs. French: Pads, 14/18lbs. net; boxes,

6, 9, or 12lbs. net; sieves, 14/18lbs. net. German: Baskets, 17/18lbs. net; large baskets, 36/40lbs. net.

Red and Black Currants.—English: Half bushel, 24lbs. net; half pots, 32lbs. net; pots, 63lbs. net. French: Flat handle baskets, 7/9lbs. net.

Apples, Pears, etc.—English: Pot of 64/72lbs. net. French pears in boxes of 15, 30, 36, 48, 60, 70 pears per box. French pears in long cases (coffins), say 64lbs. net. French apples in cases of about 40lbs. net. Belgian pears in boxes of about 36lbs. net. Belgian pears in mollies of about 16lbs. net. German pears in mollies of about 32/36lbs. net.

Gooseberries.—English: Half bushel, 28lbs.

Strawberries.—Gallon baskets, 6lbs. net; pick baskets, 12lbs. net; sieves, 12/15lbs. net.

Green Peas and Beans, English, hampers of 40lbs. net.

Broccoli, Cornish, crates of 4 to 6 dozen.

Lettuce, French, in flats containing 3 to 3½ dozen.

English Marrows, Beets, Horse-radish, Cucumbers, Cabbage, Carrots, Turnips, and also various Herbs are sold per dozen.

London.—Markets every week day. Covent Garden for fruits and flowers; and for vegetables, Farringdon, Borough, and Spitalfields.

The ordinary packages are:—

Apples.—Kitchen and dessert in sieves, choice dessert in halves.

Pears.—Choice in halves, common in sieves.

Plums.—Damsons in halves, gages in pecks and halves; plums in halves.

Cherries, Gooseberries, and *Currants* in halves, containing 24lbs.

Raspberries, without stalks, "slipped" or "plummed," in tubs 30lbs. and 50lbs. each.

Strawberries in gallons and pecks; choice in ½lb. and 1lb. punnets.

Dessert Gooseberries, ripe, in 1lb. punnets and gallons.

Choice Pears in boxes of 2 dozen.

Raspberries, with stalks, for dessert, 1lb. punnets.

Cob-nuts in sieves of 50lbs.

Potatoes.—*New*: 1 cwt. bags, or sieves of 8 gallons; *Old*: In 1 cwt. (2 bushels), or at per ton.

Greens.—Brussels sprouts in half sieves. Headed cabbages, 60 to a tally, in pads and crates; cauliflowers, in bunches of 12, collards in bunches of 12, at per dozen bunches.

Onions.—Per 1 cwt. bags.

Parsnips.—Bunched, or per ton.

Carrots.—Bunched, or per ton.

Turnips.—Early, in bunches; late, in 1 cwt. bags.

Celery.—Per doz. heads.

The markets for vegetables of all kinds vary from season to season, and the leading kinds only are quoted in the reports.

Fruit Punnets.—½lb., 1lb., and 4lbs.

Sea-kale Punnets. — Eight inches diameter at the top and seven and a half inches at the bottom, and 2 inches deep.

Radish Punnets.—Eight inches diameter, and one inch deep, if to hold six hands; or nine inches by one inch for twelve hands.

Mushroom Punnets.—Seven inches by one inch.

Salading Punnets.—Five inches by two inches.

Half Sieve.—Contains 4 imperial gallons. It averages 12½ inches in diameter and 6 inches in depth.

Sieve.—Contains 8 gallons. Diameter 15 inches, depth 8 inches. A sieve of currants, 20 quarts.

Bushel Sieve.—Ten and a half imperial gallons. Diameter at top 17¾ inches, at bottom 17 inches; depth 11¼ inches.

Bushel Basket.—Ought, when heaped, to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, nuts, apples, and potatoes are sold by this measure. A bushel of the last named, cleaned, weighs 56lbs., but 4lbs. additional are allowed if they are not washed. A *junk* contains two-thirds of a bushel.

A *Pot* contains 2 bushels.

Fruit Peck contains 12lbs.

Pottle.—Is a long tapering basket made of deal shavings, and holds rather

over 1½ pints. A pottle of strawberries should hold ½ gallon, but never holds more than 1 quart; a pottle of mushrooms should weigh 1lb., but pottles seem to have gone out of fashion lately.

Hand.—Applies to a bunch of radishes, which contains from 12 to 30 or more, according to season.

Bundle.—Contains 6 to 20 heads of broccoli, celery, etc.; seakale, 12 to 18 heads; rhubarb, 20 to 30 stems, according to size; and of asparagus, from 100 to 125.

Bunch.—Is applied to herbs, etc., and varies much in size, according to the season. A bunch of turnips is 12 to 25; of carrots, 15 to 40; of greens, as many as can be tied together by the roots.

Grapes.—Are put up in 2lb. and 4lb. punnets; new potatoes, by the London growers in 2lb. punnets. Apples and pears are put up in bushels, sieves, or half sieves. A hundredweight of Kentish filberts is 100lbs. Weights are always 16 ozs. to the pound.

Manchester. — Smithfield Market (Shude Hill) is the important centre, no other market in the kingdom, save London, receives and distributes such a vast amount of fresh fruit and vegetables. *Tuesday* is the biggest day, and then come Thursday and Saturday.

Nottingham. — Tuesdays, Wednesdays, and Fridays.

Apples are sold by the cwt., and by the strike of 64lbs.

Pears by the cwt., and by the strike of 72lbs.

Plums and *Damsons* by the pot of 72lbs.

Tomatoes by the lb.

Strawberries by the peck of 12lbs.

Red and Black Currants by the stone of 14lbs.

Gooseberries by the peck of 16lbs.

Potatoes sold by the ton, and to small buyers by the strike of 84lbs.

Onions, Carrots, and Broad Beans by the cwt. or ton.

Runner Beans by the pot of 40lbs., or bushel of 32lbs.

Brussels Sprouts, on the stalks, in bundles of 12.

Brussels Sprouts, off the stalks, by the stone of 14lbs.

Sheffield. — Tuesdays, Thursdays, Fridays, and Saturdays.

Potatoes.—Half load bags, containing 9 stones, or 1 cwt. 1 quarter. Two bags to one load.

Onions, Parsnips, Carrots, Beet, and other Cereals.—Sold in bags of ½ cwt. or 1 cwt. each.

Kidney Beans.—Per bushel of 32lbs. each.

Peas.—Per bag of 40lbs., also per bag of 80lbs. each.

Apples, Pears, Plums, Gooseberries, and other Fruits in Bulk.—In all kinds of packages, whether in sieves, ovals, pots, London or Kent baskets or barrels, at per cwt. of 112lbs.

Raspberries.—At per quart or cwt.

Strawberries.—At per peck or per lb.

Cabbages, Cauliflowers, Savoys, and Others.—At per dozen.

Nearly everything in Sheffield is sold by weight and count. Buyers usually wish to see everything they buy weighed or counted before they leave. Very little is sold at per package. Kent strawberries, Worcestershire radishes, Cornish broccoli are among the exceptions.

Foreign Fruits.—Are sold at per case, barrel, or bag. Particulars are given of contents, or about, as far as is known, or as advised by the sender. When goods are retailed those fruits that require counting are sold at per hundred of 120 and per dozen, and those by weight at per stone of 14lbs.

AVERAGE WEIGHTS PER PECK

Potatoes, 20 lbs.	Green peas, 8lbs.
White turnips, 16lbs.	Apples, 16lbs.
Swede turnips, 18lbs.	Pears, 18lbs.
Onions, 16lbs.	Strawberries, 12lbs.
Broad beans, 9lbs.	Gooseberries, 16lbs.
Kidney beans, 10lbs.	Plums, Damsons, and other stone fruit, 18lbs.
Scarlet runners, 8lbs.	

Digestion of Vegetables.—Many green vegetables contain large proportions of elastic, fibrous, and woody tissue, which are very indigestible; and various sorts contain starchy matter, which require thorough cooking to burst the cells of the starch to make it digestible. These cells are especially liable to be swallowed in lumps—the outside of which may be soft, but the centre hard and quite impenetrable by the digestive fluids. To prevent this, they should be crushed with a fork at the time of eating—a precaution which will enable many delicate persons to digest potatoes, carrots, and the like, who could not otherwise touch them with safety.

Value of Uncooked Fruit. — Fruit taken in the morning is as helpful to digestion as it is refreshing. The newly-awakened function finds in it an object of such light labour as will exercise, without seriously taxing its energies; and the tissues of the stomach acquire at little cost a gain of nourishment which will sustain those energies in later and more serious operations. It is an excellent plan, with this object in view, to take a little bread with the fruit eaten. Fruit is the chief article of a Dutch child's diet; and, under certain precautions, it does well. In Germany, scarcely any household omits the daily dish of baked apples, which are acknowledged by all to be most excellent and nutritious food.

Why for ages have people eaten apple sauce with their roast goose and sucking pig? Simply because the acids and peptones in the fruit assist in digesting the fats so abundant in this kind of food. For the same reason at the end of a heavy dinner we eat our cooked fruits, and when we want their digestive action even more developed we take them after dinner in their natural uncooked state as dessert. Cultivated fruits, such as apples, pears, cherries, strawberries, grapes, etc., contain on analysis very similar proportions of the same ingredients, which are about one per cent. of malic and other acids, and one per cent. of flesh-forming albuminoids, with over eighty per cent. of water.

Digestion depends upon the action of pepsin in the stomach. Fats are digested by these acids and the bile from the liver. Now, the acids and peptones in fruit peculiarly assist the acids of the stomach. Lemon juice has been prescribed largely by physicians to help weak digestion, simply because these acids exist very abundantly in the lemon.

Green Peas.— F. *Petits Pois;* G. *Grünen Erbsen;* Port. *Ervilhas;* Sp. *Guisantes;* W. *Pys gleison.*

Retailers in buying these in sealed bottles or tins will do well to obtain a guarantee as to their purity or harmlessness. It is often said that they are artificially coloured green with sulphate of copper; although, as a fact, there is never really a particle of sulphate to be found in them when washed. Sulphate is admittedly often added to the peas in sterilising and preserving them, but it then enters into an insoluble combination with the peas, and thereupon ceases to be sulphate. They are afterwards well washed. The green is not imparted to the peas by the sulphate, but is the natural colour of the peas themselves, which the sulphate merely fixes or preserves.

Petits Pois or *Gros Pois* are the French terms for "small green peas" or "large green peas," gathered quite young. Large quantities come from France, Holland, and Germany every year in wood cases of fifty 2-lb. or a hundred 1-lb tins, or 24 bottles, and of various qualities. Immense quantities are prepared near Paris, Le Mans, and Nantes. Around Nantes in abundant years some 250 tons are preserved during the season. They are usually graded as *Moyens* (medium), *Fins* (fine), *Très fins* (very fine), *Sur fins* and *Extra fins* (extra fine).

The small metal labels on the continental tins are unreliable and no guarantee that the contents are according to English law. They have never, except theoretically, been proved to be poisonous. Colouring with copper is not strictly illegal—a little mineral colouring being permitted in England, but magistrates differ as to *how much.* In France a larger amount of copper is allowed, so that the peas most beautiful in appear-

ance are possibly the most dangerous, or at all events subject the sellers in this country to fines. There is, however, now a process by which *chlorophyl*, the innocent and beautiful green which forms the natural colouring matter in the plant world, can be separated from leaves and vegetables, such as Spinach, and applied to heighten the hue of peas and other preserved vegetables, and this is supplanting the "coppering" processes.

Large quantities of canned peas have been lately coming from Denmark, where *Fairbeards Nonpareil* are held to be the finest and best.

Preserved or tinned peas may be done in same way as fruits. The rationale of the process being that putrefying germs existing on the surface of the peas are destroyed by the heat, and fresh putrefactive agencies are prevented from gaining access, by the total exclusion of fresh air.

Shell the peas, put them into dry wide-mouthed bottles, shake them down, cork the bottles closely, and seal the corks air tight. Bury the bottles in the driest part of the garden, and take them up as wanted. They will keep good five or six months.

Another way.—Choose peas which are large and fully grown, though not old. Put them into bottles, cork securely, and tie with bladder. Tie a whisp of hay round the lower part of the bottles to prevent their knocking against each other in the pan. Put them side by side in a large pan, and pour into it as much cold water as will reach to their necks. Put the pan on the fire, and let it remain for two hours after the water has reached the boiling point, then take it off, but do not remove the bottles till the water is cold. Seal the corks, and store in a dark, dry place.

Vast quantities are now canned in Italy and America, especially in Jersey and Brooklyn, the peas being shelled by machinery. One man, two boys, and a machine can shell about 1,800 bushels in a ten hours' day.

Peas when preserved in tins, hermetically sealed, are also said to be liable to undergo some very peculiar decomposition and become poisonous; it is fancied that a poison is developed from some change in the *legumin* analogous to the formation of the cadaveric alkaloids. Foreign packed peas, besides being generally treated with copper, which is sometimes effected by boiling the peas in copper vessels, and sometimes by plunging them for five or ten minutes in a boiling solution of sulphate of copper, have occasionally been supposed to contain other poisonous substances, such as tin and lead or zinc. The copper salts used are, however, almost too small to exert any toxic or injurious action.

Sulphate of copper itself, which is a soluble salt, may be taken in a pure state in quantities 10, 20, or 30 times larger than ever used in peas without doing the slightest apparent harm. Doctors, in fact, used to prescribe it in larger doses, and it has been taken by patients for months and years. Yet, although no fatal cases have been proved other doctors argue that small doses of these copper salts induce a variety of gastric and intestinal troubles, which are liable to be put down to all sorts of causes other than the true one.

For more than 40 years this sulphate of copper has been used in minute quantities by the French packers for the purpose of fixing or retaining the natural colour of peas and other vegetables. During these 40 years hundreds of millions of tins and bottles of these foods have been eaten, but never has there been a single well-authenticated instance of poisoning or other injury that could be definitely traced to the minute proportion of copper used in the process. While not believing in half the scare-head statements and sensational press paragraphs, everyone is bound to regard the law.

There are at least over 20 million tins of them consumed annually.

Doctors Paul, Stephenson, Luff, and Quain all aver that such peas are quite innocuous, and the writings of Guy, Ferrier, Dicksonhiam, Phillips, and others, assert the same. Green peas are best when heated or boiled for about 20 minutes in the tin, after a vent-hole has been made.

How Copper is detected.—A weighed

quantity is made into a paste with water and a little hydric chloride, and then placed in a platinum dish. A rod of zinc, on being pushed into the paste so as to touch the dish, sets up a galvanic current, and at the end of several hours all the copper is deposited as a coherent film, and may be dried and weighed. A neater process is the connection of the platinum dish with the negative pole of a battery, while the positive pole is suspended in the acid paste. The peas must, of course, be burnt to an ash before the exact amount of copper can be estimated.

Carbonate of soda is commonly added to green peas in cooking them, to improve the colour.

The surplus liquor should be drained off, and the peas should be served while piping hot. The addition of a few fresh mint leaves and a little sugar is an improvement.

As with all tinned foods, rusty tins should always be rejected.

Leading Merchants.—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; J. A. Sharwood & Co., Ltd., St. George's House, London, E.C. (the largest dealers in the world).

Green Soap or German Soft Soap (sometimes called "Green Salve").—An official preparation of soft soap made from potash and linseed or hempseed oil, coloured with indigo and used in the treatment of eczema and other cutaneous diseases.

Green Teas. — Chinese, *Luh cha* (green tea); Lat., *Thea viridis*, as distinguished from *Thea bohea* (black tea). (See also *Teas, Blended Teas*, etc.)

The finest green teas are prepared in China, and consist of the young unopened leaf-buds of the tea plant, and are known best in England as Hyson, Hyson Skin, Young Hyson, Gunpowder, Imperial, and Tonkay or Twankay, according to the way the grower rolls the green leaf.

These are dried by a quicker process and at a higher temperature than black teas, and therefore contain less moisture. The colour is or should be entirely due to the rapid drying of the fresh gathered leaves, which prevents the chlorophyl, or natural green colour, undergoing much alteration.

In curing the leaves they are worked up into little rolls by hand and roasted in dirty copper pans over a wood fire within an hour or two of being gathered, usually in the afternoon, while the leaves for *black* tea are allowed to lie in heaps for ten or twelve hours, during which time they undergo a sort of fermentation and are dried very slowly. In China the brighter green leaves of the hardiest plants are usually selected for making into the best green teas.

But it is said that the green tea sent out of China for the foreigner is almost invariably "faced," dyed, or glazed with artificial colouring matter, usually a powdered mixture of gypsum and Prussian blue. Sometimes they owe much of their colour to being mixed with weeds, shrubs, and grasses.

Green teas are prepared very extensively in both China, Japan, and Ceylon, and the natives of Russian Central Asia drink none but these; although the demand in Europe has greatly fallen away these last dozen years. There is also a great fancy for green teas in Canada and the United States. The Ceylon growths seem to be displacing all others.

Some is now made in India, and in the North-West Provinces the leaves (gathered dry) are at once sweated and softened by heat, then rolled and exposed in the sun till they turn a darkish colour, and rolled again. When sufficiently rolled, they are all heated till too hot to be stirred by hand.

The tea is next tightly packed in a strong canvas bag and beaten so as to consolidate it, and then left for a few hours.

It is finally "fired," or dried off in a pan for about nine hours—beginning with a high heat, which is gradually reduced—while it is also being well stirred and tossed about the whole time. If kept in the original packages for a great length of time, green teas become what is called "boxy."

Indian green tea is never "faced," or artificially coloured, with foreign substances. It yields a light-coloured

liquor of high fragrance, but thin, sharp, and somewhat rasping in taste compared with *black* tea. The Indian product, however, is inferior to the best Chinese green tea, and only fetches about half the price. The Russians seldom use any other; they are partial also to a squeeze of a lemon in their tea, instead of milk or sugar.

The different processes employed in the manufacture of green tea seem to develop a much larger percentage of the narcotic principle than is the case with ordinary black tea.

A cup of strong green tea, without milk or sugar, is a popular and generally efficient remedy for a severe nervous headache. It has a rather serious effect upon the nervous system and the digestive organs if frequently taken strong; producing with some people tremblings, giddiness, and headaches; and tried on small animals, has even caused paralysis.

(For green brick tea, see *Brick Tea.*)

Green Turtle.—See *Turtle Meat.*

Green Wines.—A technical name for wines during the first year after making.

Greengages.—F. *Reine Claude;* It. *Regina Claudio.*

A moderate-sized species of the *Prunus domestica,* but the most esteemed of all. It was first brought to England by a member of the Gage family from the monastery of Chartreuse — hence its name. This family obtained from the monks of Chartreuse, in Paris, a collection of fruit trees. Among others was one named "*La Reine Claude,*" but the name having got rubbed off, Lord Gage's gardener was at a loss to know what it was. When the tree bore fruit he was surprised to find that its green state did not change as other plums do, so he gave it the name of "Green Gage."

In preserving greengages—either as bottled fruit, as jam, or as crystallised fruit—their appearance may be much improved by adding a little soda or potash to the water in which you commence to boil them, otherwise they will assume a yellowish cast.

The green colour of fruits and leaves depends on the amount of alkali they contain; and in proportion as acid or alkali prevails in them, so they are colcured from red to violet, blue, and green. Every cook knows how soda, potash, or muriate of soda (common salt) gives a fresh green appearance to her greens or cabbages in boiling.

The best kinds for jam-making are the English growths. They should be full-grown, but still hard, and not nearly ripe. Each fruit should be pricked to the stone in several places with a fork, so as to cook readily and admit sugar. As soon as pricked they should be thrown into cold water, or the colour will be spoilt by the prongs of the fork. They should afterwards be boiled very slowly, and well stirred during the process.

Some manufacturers add a little sulphate of copper or other copper compound to preserve or intensify the green colour; but these, although not positively injurious in minute quantities, should be avoided.

Gregory's Powder.—The first is the original formula of Dr. Gregory, of Edinburgh:—

2½ ozs. magnesia, 1 oz. powdered Turkey rhubarb, and ½ oz. powdered ginger.

2. The *British Pharmacopœia* (1898) requires: Rhubarb powder 22·2 per cent., magnesium oxide 66·7, powdered ginger 11·1 per cent.

3. That of the Edinburgh and Dublin pharmacopœias:—2 ozs. rhubarb, 6 ozs. magnesia, and 1 oz. ginger.

4. A form commonly made up by druggists for special uses in hospitals, etc.:—Magnesia 10 parts, rhubarb 5, ginger 3.

The powders are popular ant-acids, stomachics, and mild purgatives, used for colic, diarrhœa, and dyspepsia. Dose: 20 to 60 grains.

Retailers should be careful that these powders are not prepared with ordinary carbonate of magnesia instead of the legal *oxide.*

Gardner's patent "Rapid" sifter and mixer freely used for above. Prices from 50/- to £100. Catalogues from

Wm. Gardner & Sons, engineers, Gloucester.

Griddle Cakes, or Crumpets.—Thin cakes (also called girdle cakes) made of pancake batter, thinned down with milk and sweetened with sugar, and cooked over the fire on a broad disc or grated utensil (of tin) for cooking fish. ("Griddle" is the Scotch word for "gridiron.") Or the batter may be dropped on a greased girdle or muffin stone, run out to the size of a small cheese plate, baked to a nice brown, and then turned. (See also *Pikelets.*)

Griskins.—See *Pork.*

Grist. — Wheat-flour or meal from which the coarse bran only has been taken. In America "grist" is a name applied to the corn taken to a mill by a customer to be ground.

Grits.—See *Groats.*

Groaning Cheese.—A name given to the cheese forming part of the *blythemeat*, or entertainment provided at the birth and christening of a child. In *Pop. Antiq.*, 1777, p. 403, we read:—"It is customary at Oxford to cut what in the North is called the 'groaning cheese' in the middle when the child is born, and so by degrees form with it a large kind of ring, through which the child is passed on the christening day."

Groatine. — This consists of oats which have been freed from their husks, and then simply crushed or flattened out to about the size and thickness of a sixpence between a pair of rollers.

Groats, or Grits. — F. *Gruau d'avoine;* Lat. *Avena decorticata;* W. *Rhynion.*—(See also *Embden Groats.*)

These are the seeds or kernels of oats which have merely been deprived of their exterior integuments or husk.

This decortication is generally done in mills, some of which also cut the grain into two or three pieces, while some leave the grain in its proper form. They are used chiefly for making gruel and for thickening broths, soups, etc. White groats require more care in milling than brown or black oats. A boll of 6 bushels, say 45lbs. to the bushel, produces about 165lbs. of finished white groats, 18lbs. of groat dust (see *Sowans*), 14lbs. of grey dust, and 42lbs. of seeds.

Leading Manufacturers. — Keen, Robinson & Co. (Robinson's Patent Groats), Garlick Hill, London, E.C.

Grog (Spirit and Water). — See *Spirits.*

Ground-Nut Oil. — See *Arachis Oil.*

Ground Nuts, Pea Nuts, or Gouba Nuts.— F. *Arachides;* G. *Erdnusse;* It. *Arachidi;* Sp. *Arachide, Mani.*—(Known also as *Arachide* or *Arachis Nuts, Bambarra Nuts, Manilla Nuts, Jur Nuts, Earth Nuts, Pindas* or *Pindal, Basket Nuts, Mandubin Nuts, Monkey Nuts, Mpinta,* or *Ginguba,* etc., and often erroneously called *Castor-oil Nuts* and *Pistachio Nuts.* These nuts, which have a great number of names, are the produce of a species of the leguminous plant, *Arachis hypogæa,* of the pulse family, and perhaps *Arachis Nuts* is the most comprehensive title. They were first introduced in 1840, are unknown in a wild state, and whether native of Brazil or Africa is uncertain, but they are now cultivated in most of the tropical and semi-tropical climates, particularly in the Southern States of America, in Africa, India, Senegal, Pondicherry, and Karikal; also in China, and have become an important article of commerce especially in India, whence some 100,000 tons are exported yearly, besides a large quantity of oil (see "*Arachis Oil*"), while in China they are invariably to be found on every roadside stall throughout the country.

Ground nuts, indeed, form one of the principal exports of the eastern districts of the Madras Presidency. Mandubin, Mpinta, or Ginguba nuts are African names for these nuts.

The plant, a sort of trailing vine, resembling clover, is an annual, and grows readily on poor soil to the height of 1 or 2 feet. The seeds are planted or dibbled in October or November.

It has a branching stem 9 to 18 inches high, with hairy pinnate leaves, having four broad blunt leaflets in pairs. The flower is yellow, and produced singly in the axils of the leaves. The stalks grow longer, and after flowering turn their heads towards the ground and work themselves into the earth, where the pods grow and ripen. The first crop of seeds for eating green is ready in April, but are not ripe for export as oil yielders till July or August. When the nuts are ripe the plant dies, and has to be pulled out of the earth by hand, hence the name Earth or Ground nuts. After being picked up the pods are dried and cleaned in a winnowing machine, sometimes bleached with sulphur or *decorticated*, and then bagged for export. The pod, about ¾ of an inch long and contracted in the middle, is rough, brittle, and of a pale yellow colour. When crushed between the finger and thumb each pod is found to contain two or three seeds or kernels similar to those of hazel nuts, of a sweet aromatic flavour (especially if roasted), containing about twenty-four per cent. of flesh-forming elements. These nuts belong to the richest of all known sorts, analysis having shown them to consist of as much as 48 to 50 per cent. of crude fat. The hulls or shells have only a manurial value, but *Pea-nut Hay* is a nutritious food for cattle, and a very suitable substitute for clover hay. Two kinds of nuts are cultivated, the white and the red; the latter ripen better, because earlier. Large quantities are raised in Tennessee, Virginia, and North Carolina, and the annual crop of the United States alone is estimated at about 3,000,000 bushels. In Spain the nuts are often ground up and mixed with chocolate. They are said to be a good remedy for insomnia and indigestion, and are used in America for making a imitation chocolate. For this purpos they are beaten up in a mortar and th mass compressed into cakes, when it is said to form a very agreeable chocolate without a particle of true cocoa. *Pea-nut Candy* is another popular American confection. The Americans also use the seeds as a dessert sweetmeat by parching them and beating them up with sugar. They are sometimes sold ready roasted. A powder is also prepared from them. (See *Earth Nut Meal* and *Pea-nut Biscuits*.) There are several factories in Ohio and Indiana.

Gouba Nuts, or "*Goubers*," are a variety native of Tennessee. Their distinguishing feature is their shape, and one shell frequently contains half-a-dozen kernels. These are the most productive variety, but least palatable and most indigestible, being usually full of grit, unsound, imperfect, and are mostly sold at fairs, in circus tents, etc.

Bambarra Nuts (*Voandzeia subterranea*) are also called Ground Nuts, but they are a different and smaller species, grown largely in Zanzibar, and only contain a single seed in each pod. They are used as food only and not for oil pressing.

Besides the above, there are the Virginia, running and bunch; the Georgia, white and red; the small North Carolina, and the Spanish.

The Virginia varieties, being most widely known and popular with the trade, are the ones commonly planted. There is little difference between the Virginia and Tennessee nuts, both being sold as "Virginia hand-picked" pea-nuts.

The Spanish nut has a small kernel of fine quality, and is in demand as "confectioners' stock," being worth several cents per pound more than any other shelled stock.

While an open, sandy soil which does not stain the shell is the ideal one for the pea-nut, it thrives on any friable soil that contains a sufficient quantity of lime and humus. The presence of lime is necessary for the development of the nuts, as without lime there may be luxuriant vines bearing nothing but pods.

Pea-nut oil is used for lubricating and soap-making, and is a good substitute for olive oil for salads and other culinary purposes, and as a substitute for lard, cottolene and butter in cooking. The residue from oil-making, known as "pea-nut cake," is a highly-valued cattle food in the countries of Europe, and is also ground into fine flour and used as human food.

Virginian pea-nuts are much sought after by dealers, and when well harvested are the most handsome in appearance, the shell being nearly pure white. They are cultivated in rows, like potatoes, and are liable to be discoloured by rain at harvest time. Their appearance being thus injured, they have to be marketed cheap, as "off colour." These discoloured nuts are often subjected to a bleaching process in chloride of lime, and made white as the best; but they are apt to emit a bad flavour when roasted, and are not so salable. During the last few years immense quantities of these nuts have been imported, and appear to keep well; but having thin shells should not be much exposed to the sun.

The best come from Senegal, and the lower grades from Madras, Pondicherry, and Cuddalore. The nuts from America and West Africa arrive usually in the shell, packed in bales of 150lbs. each, but in East Africa and India they are often threshed out by machinery, and the kernels only exported. Deprived of their shell, these nuts represent pretty closely the kernels of ordinary filberts, and are indeed often mistaken for such. Blanched and prepared, they often pass in cakes and confectionery as sweet almonds, especially when ground; their cost being but one-fourth that of genuine sweet almonds. (See also *Pea-nuts.*)

Approximate prices: Undecorticated, 7/6 per cwt.; decorticated, 11/- per cwt.

Special Merchant.—M. E. Holdsworth, 3 Norfolk Street, Bradford.

Ground Rice. — (See also *Rice Flour.*)—Generally made from broken rice, the grains of which are often badly broken by the machines during the husking process.

Gruau. — The French name for decorticated grain, such as pearled wheat, barley, or groats, for soups, gruels, etc.

Gruau de Bretagne is a crude preparation, and much the same thing as our Scotch barley, but is very popular in both Brittany and Normandy.

Gruau de Paris is a more refined product, obtained by passing the dried and hardened grain—wheat, barley, or oats—between mill-stones set wide enough to remove the outer skin without breaking the grain itself.

Semoule de Gruau is a name for semolina or decorticated wheat when crushed or cut into hard granules, and these when sifted into three or four sizes are known as *Farines de Gruau*, firsts, seconds, thirds, small, etc.

The name *Pain de Gruau* is given to a fine kind of white bread made in France, and particularly popular in Paris. It is made from the coarser or larger kinds of semolina.

Gruyere Cheese.—F. *Fromage de Gruyère;* G. *Schweizer Käse;* It. *Griviere;* Port. *Queijo de Suissa;* Sp. *Queso Suisso.*

A popular kind made from skimmed or partially-skimmed cows' milk in the Jura regions of both Switzerland and France, and also in several parts of the Vosges Mountains.

Gruyère cheese is an intermediate between the hard and soft cheeses, but is quite firm and dry, and of a pale yellowish colour. It is notably traversed by numerous cavities, air bubbles, or cells and passages, and is one of the kinds most often used in cooking macaroni and certain other Continental dishes.

The original, and perhaps the best, is the Swiss, and took its name from Gruyère, a small town and valley in the Canton of Fribourg, Switzerland, where the cheese is made from a mixture of goats' and ewes' milk. Ordinary weight about 1½ cwts. each. Composition:—Water, 34·68; casein and albumen, 31·41; fat, 28·93; milk sugar, 1·13; and ash, 3·85.

In making them, the milk is set at 82° to 86° F., the curd is first cut and then broken, and then allowed to settle for ten minutes. The curd with the whey is next heated to 140°, and this causes the curd to become tough and hard. The curd, after the whey is pressed out, is put in vats and submitted to very heavy pressure, after which it is dry clothed and put into a dampish cellar, where it is systematically salted with dry salt, also strongly flavoured with the dried and powdered herb *Melalitus officinalis*, so that when ready for consumption it is of close texture, except where the serum or

whey has collected and formed large holes.

These cavities, or air cells, are largely due to the chemical action of the whey, the sugar contained becoming, during the ripening, converted into alcohol and carbonic acid, which by its expansion, while escaping, produces the vesicular texture, so peculiar to this cheese.

The French Gruyère contains more numerous but smaller holes in it, and its production in the three departments (Jura, Doubs, and Ain) on the confines of Switzerland increases yearly, and supplies over three-quarters of the cheese made in France; but in Switzerland it remains stationary, although the industry dates back to 1636 at least.

These French factories deal with over 10 million gallons of milk yearly (say 20,000 tons of Gruyère). In fact, cheese-making and watch-making form the staple industries of the whole region. Each village has its own "*fruitier*," or co-operative manager, whose duty it is to receive the milk from the farmers, make it into cheese, and market it, each farmer in turn receiving back his proportion of the whey for pig-feeding. The factory, or "fruiterie" is parish property, and the *fruitier* is paid his salary from the same source. Irreproachable cleanliness is enforced, and the smallest speck of dirt on the milk vessels compels the fruitier to reject the milk. The cheese is made into huge grindstone-shaped blocks, about 3 feet in diameter by 6 inches thick, which are finally packed in large tierces holding 8 or 12 cheeses.

Gruyère cheese, on account of its strong and peculiar flavour, is, however, not generally liked by English people.

Further remarks as to management will be found under "*Swiss Cheese*."

Guaiac Soap and **Guaiacum Resin.**—The soap is composed of liquor potassa and guaiac.

Guayacan, or *Guaiac*, is the native name of the plant in South America.

Guaiacum resin is brittle and of greenish-brown colour, and is obtained from the stem of the guaiacum tree.

Guango Beans.—See *Rain Beans*.

Guanos.—From the Peruvian word *huano* (dung).

This valuable manure consists of the decomposed excrement, more or less fossilised, of sea fowl which congregate in prodigious swarms all along the shores and adjacent islands off the coast of Peru and Bolivia, and on other parts of the Southern Pacific coast, where the climate it hot, dry, and free from rains. In some of the islands deposits have been found 50 to 60 feet in thickness; and those on the Chincha Islands, now exhausted, were originally about 200 feet thick.

Guanos have only been imported into this country largely since 1841, in which year it was introduced by the Earl of Derby. They are of various qualities, and their values should be calculated from the amount of nitrogen, salts of ammonia, and phosphates which they contain.

Some kinds, having lost nearly all their ammonia through atmospheric exposure and decomposition, are of comparatively little value. Guanos should therefore be covered up well as soon as laid on the land, and "top-dressing" is certainly the most wasteful way in which they can be applied.

Some kinds are largely contaminated with sand, and colour is scarcely any criterion—some authorities giving the preference to the whitish varieties, which are believed to be more recent, while others prefer the red guanos.

The best are those which retain most of their original constituents, and should contain about the following percentages:—52 per cent. of organic matter and salts of ammonia, 23 of phosphates, 13 of moisture, 10 of alkaline salts, and 2 of sand—altogether equal to over 16 per cent. of ammonia.

The high state of agriculture in this country is mainly indebted to the fertilising powers of guanos, but, unfortunately, Peruvian guanos are becoming exhausted and of inferior quality, being principally phosphatic. Guano is no longer protected by a monopoly, and there is little prospect of new deposits being discovered. Of the Chilian export quality, containing under 15 per cent. of

sand, not more than 70,000 tons remain.

Fray Bentos Guano is an artificial kind prepared in the Uruguay Meat Extract Manufactory. It is in the form of a fine dry powder smelling of glue and resembling meat flour.

Australian Guano is a sort found on the Lacepede Islands, on the north-west coast of Victoria.

Another kind is known as *Fish Guano*, made from the refuse of all kinds of fish, bad fish, etc. Most of this is made in Norway and Newfoundland from the cod and herring offal; some is made in London, Hull, etc., of bad fish, which is usually dried and ground to a floury powder.

Guarana.— (Also known as *Guarana Bread*, *Sticks* or *Tea*, *Brazilian Cocoa*, etc.)—It consists of a kind of paste used as food and medicine, and is prepared from the seeds of the climbing plant *Paullinia sorbilis*, by the Guaranis and other savage tribes in the Amazon Valley of Brazil, taking its name from the former. It is first made in rolls like sausages or oblong cakes, and from which pieces are afterwards broken, and pounded in water and sweetened, when it is greatly esteemed as a valuable and refreshing beverage.

It contains 3 to 5 per cent. of the crystalline or alkaloid, called guaranine, which is similar to the *theine* of tea and the caffeine of coffee, and is used as a cure for megrims or sick headache. Guarana was introduced to special notice in this country first in 1856 and again in 1870.

Guatemala Coffees. — (See also *Coffee*.)—The export of coffee is the sole form of wealth which Guatemala possesses, and the cultivation of coffee is now absorbing the attention of almost all the landowners, although the tropical situation of the country, the proximity of every portion to the sea on both coasts, the diversity of altitudes, and consequently temperature, should combine to make its agricultural capabilities equal to any in the world.

The principal districts of the coffee-growing industry are found in the departments of Quezaltenango, San Marcos, Chimaltenango, Santa Rosa, Retalhulen, Escuintla, Zacapa, and Alta Vera Paz. The conditions essential for the growth of coffee are, in this latitude, an altitude of from 2,600 feet to 4,500 feet above the sea level, a considerable depth of vegetable soil and a clay subsoil. Lands of this description are found in almost every department of the Republic. The coffee tree is easily cultivated. The young trees are planted in little pits about fifty centims. deep, and at a distance of about 1½ metres from each other. Every three months the plantation needs thinning out, and the first harvest is obtained the third or fourth year after planting the trees.

In the lowlands of Guatemala, *Coffea liberica* is the variety which flourishes best, its harvesting being also facilitated by the fact that its rich, heavy berries, when ripe, do not drop to the ground, an important point in that country, where labour is comparatively dear, although only some 19 to 25 cents. a day for Indians.

After being cured, dried, and hulled, the beans are sorted into "firsts," "seconds," and "thirds," and then packed into Dundee or Calcutta sacks of 130 to 135lbs. nett each. These are sent on the backs of Indians or mules, or in carts drawn by oxen to the nearest railway station for a port of shipment. The "firsts," or *vera paz*, usually go to London, the "seconds" to Germany, and the "thirds" to the United States.

The chief port of shipment is Champerico, and the exports, which are increasing yearly, already amount to 50 or 60 million pounds.

Guavas.—F. *Goyave*; Port. *Guyava*; Sp. *Guyaba*.

Guava Cheese, Guava Jelly, Guava Marmalade, and Guava Wine are all preparations from the fruit of various guava shrubs or trees of the *Psidium guajava*, which grow wild in the West Indies, Central America, Madeira, and some other countries, but two or three varieties are now cultivated and naturalised in most of the tropical and sub-tropical regions. There are at least seventeen different species. They are usually propagated from the seed, and prefer rich moist ground,

The *common pear-shaped* or *white guava* tree, *P. pyriferum*, grows 10 to 20 feet high, all over Ceylon and West Indies, and resembles a cherry tree, but with larger and longer, smooth, opposite leaves, which have an aromatic taste, and are often chewed by the natives. The flowers are of pure white colour, have a very sweet and delicious scent, and are not unlike a large white myrtle blossom. One variety, good for making into jelly, is a brownish yellow, round or pear-shaped in form, about the size of a hen's egg, very smooth, sweet, and aromatic, tasting something like figs; but of an astringent nature, while most other fruits are laxative; it has a thin brittle rind, and the inside contains a firm pulp of yellow hue, like the orange, but it is mixed throughout with small tough seeds of triangular form. The fruit is so very fragrant that cutting one open will scent a large room, but most varieties have a musky, strawberry flavour which is not at first liked by persons unaccustomed to its peculiar smell and taste.

The red or apple-shaped guava, *P. pomiferum*, is of a beautiful red colour, but extremely acid. It is preferred by many for eating, but not so highly esteemed as the white or yellow for making into jelly. The *Strawberry* or *Cattley Guava*, a native of Brazil, is very popular in Florida, not only for its round fruit, but also for its small white and fragrant flowers and beautiful foliage. These guavas are of the size of a small walnut, skin of a deep claret colour, somewhat resembling, but thinner than, the skin of the fig; pulp soft, fleshy, purplish red next the skin, paler towards the middle, and quite white in the centre. They have a juicy strawberry flavour. There are also several minor varieties, such as the *Black Guava*, of Jamaica, and the *Chinese Guava*, a hardy kind with smaller claret-coloured fruit, often met with in English hothouses, and in the South of France this will fruit in the open air. Like strawberries, guavas are best when fully ripe and ready to fall off. They will not keep fresh long, and it becomes necessary, therefore, to preserve the fruit quickly, either as marmalade, jelly, etc., or to make it into wine. They are also imported in tins whole, and are then good as freshly gathered.

For *Guava Jelly*. — The fruit is gathered before quite ripe, cut up, and enough water being added to keep it from burning, it is cooked for about an hour, then strained through a thin cloth. Equal quantities of the juice and sugar are finally boiled together for twenty minutes. Sometimes a little lime or lemon juice is added to improve the flavour. The rinds are often stewed in milk, and also made into marmalade. There is no reason why guava preserves should be any more costly than English jams and jellies. The fruit in Jamaica, for instance, can be had for the picking, and the best vacuum pan sugar is of course very cheap there, while the manufacture is not half the trouble of ordinary strawberry or raspberry jam.

Guava Jelly Importers.—The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Guernsey Brandy.—A kind made from beetroot spirit.

Guindre. — See *Spanish Wines*.

Guinea Coffee.—The fruit of the shrub *Coffea Guinensis*, a native of Guinea, which grows on the west coast of Africa, about 18 inches high, bears quadrifid flowers, and small, violet-coloured berries, each containing two cartilaginous seeds, pointed at the ends, but quite devoid of the valuable alkaloids found in the popular varieties of coffee.

Guinea Corn. — See *Millet Seed*.

Guinea Grains. — See *Grains of Paradise*.

Guinea Pepper. — A general term for capsicums grown in New Guinea, also variously known as Cayenne Pepper, Guinea Grains, Grains of Paradise, Ethiopian Pepper, Malaguetta Pepper, Red Bird Pepper, Chillies, etc., but more correctly applied to the species *Capsicum annuum*, a sweet or tasteless *pod pepper*, as grown in Spain and Portugal.

Gum.— Du. *Gom;* Da., G., and Sw. *Gummi;* F. *Gomme;* Sp. *Goma;* Port. and It. *Gomma*.

True gums are plant exudations, or prepared vegetable substances, which dissolve or soften in cold water, forming a mucilage, or at least a liquid of a gelatinous consistency. They are insoluble in 60 per cent. alcohol. Treated with nitric acid they yield mucic and oxalic acids. Sulphuric acid converts them into dextrin and finally into sugar.

They may be divided into five subsections, according to their chemical composition—

1. *The Arabic group* chiefly consists of arabin. They are almost entirely soluble in cold water, forming a mucilage. Examples: All kinds of acacia gums, mesquite, feronia, or wood-apple, buchanania, and acajou gums.

2. *The Cherry group*, such as cherry, peach, and apple-tree gums, consist chiefly of cerasin, and swell in cold water, forming a poor mucilage.

3. *The Tragacanth group*, namely Tragacanth, Kuteera, Nopal, Moringa, and coker-nut gums, consist chiefly of bassorin, and swell in cold water, forming a mucilage.

4. *The Dextrin group*, comprising dextrin, British gum or gommeline, consist of almost pure dextrin. It is soluble in cold water, forming a thick viscous solution, which has strong adhesive properties.

5. *The Seaweed group*, including Japan isinglass, from *Gelidium corneum*, are represented chiefly by gelose, which form a jelly with 500 times its weight of water.

In commerce gums and resins are often confounded; but gums, gum-resins, resins, and juices may be easily distinguished by rubbing their surface with water. If a gum-resin contains even a small proportion of gum, it becomes milky, which is not the case with resin. Gum-resins also char in a flame, instead of melting, and are only partly soluble in alcohol. Gums either swell up or dissolve to form a mucilage with water and char when heated. Resins and oleo-resins melt and burn readily when heated, a few however only swelling up before burning. Dried juices, like all other plant products, differ in taste, odour, or solubility in alcohol and water. Gum Elémi and gum copal are true resins; and gums of ammoniacum, galbanum, gamboge, South American hog-gum, myrrh, opopanax, cumbi, olibanum, etc., are *gum resins*.

Several of the principal sorts are described under their respective names; see also *Dextrine*, *Tragacanth*, *Arabic*, *Kauri*, *Acacia*, etc.

Gums are of various qualities and colours, but the whitest are generally considered to be the best. They are usually brittle, more or less translucent, and break something like glass. The darker hued red varieties are considered inferior.

Gum Animé is a valuable kind of African *gum resin* obtained from the *Trachylobium vernicosum*, and fetches by far the highest price for varnish making. There are four kinds, viz.: *West Indian*, in pieces about the size of hen's eggs; *East Indian*, about the size of hazel nuts; *American*, not unlike East Indian, only brown, instead of reddish-yellow, and *Oriental*, which is seldom met with.

Ghatti Gum or *Amrad Gum* is an excellent Indian kind double the strength of Turkish acacian gum, and particularly suitable for pharmaceutical purposes. It is the only kind used in India by pharmacists.

Mexican gum.—At the present time the whole of the export trade in chicle gum from Mexico is in the hands of very few persons, and the importers and manufacturers of chewing gums in the United States are also very few in number—perhaps half a dozen—who not only hold contracts with the exporters, but also refuse to sell the raw material. (See *Chicle Gum.*)

Gum Senegal, or *Acacia Senegal*, is the produce of a species of acacia, called in Egypt "Tullach" or "Tulch." It is found in many parts of Africa. When pure, it is of a dark reddish colour and opaque. It is much inferior to the best gum arabic, but is often substituted for it. Large quantities are found in Turkey, especially in the Yembo and Medina districts.

Jeddah Gum is of good quality, but not considered equal to that of

Kordofan, which is nearly white and more friable.

It abounds in the district of El Ghazel, near the sources of the Nile, and it reaches us *viâ* Khartoum and Alexandria.

There are other South African gums, *Acacia horrida* and *Acacia Giraffæ*, abundant in German territory; but these are very inferior, and only sell when Kordofan product cannot be had.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Gum Dragon. — See. *Tragacanth.*

Gum Drops. — (See also *Gelatine Goods.*)—A confection originally made in the United States from gum arabic and cane sugar, and delicately flavoured with rose, lemon, etc. When so made they have valuable demulcent properties, besides being agreeable sweetmeats.

They are, however, often made up from glucose, gelatine, starch, etc., and in this case are apt to deteriorate quickly, so as to become unsalable.

Gum (Liquid). — One that will keep:—Dissolve 1lb. gum arabic in 3 pints of cold water; when dissolved add a tablespoonful of glycerine, 1½ ozs. of honey, and 20 drops of oil of cloves. (See also *Paste.*)

To make labels stick better on glass the gum (or paste) should have a little aluminium sulphate mixed in it. For instance, dissolve 2 parts alum. sulph. in 20 of water and add it to 250 of strong gum (2 of acacia gum to 5 of water). Or take 1 oz. gum arabic, 1 oz. gum tragacanth, 40 mim. acetic acid, 1 oz. glycerine, and 2 ozs. water. Dissolve the gums in the water (hot), then add the acid and glycerine.

Gumbo, Gombo, or Okra Pods. —F. *Gombaud.*

The tapering 5-10 angled and unripe capsules of *Hisbiscus esculentus*, 4 to 10 inches long. It grows upright, not unlike a cow's horn, and pointed at the end. Called *Bendi-Kai* in Southern India. Comes from United States in tins for soups, etc.

Gumbo is, indeed, the name for Okra soup, as well as the name by which okra is often known in the Southern States. There is also a round fruited species, but the long fruited is the best known. It has several other names—such as *ketmie*, *guiabo*, *bamie*, etc.—and is usually cut before it is ripe, when it has an agreeable acid taste. (See *Okra.*)

Gumbrinskoe.—See *Russian Wines.*

Gunjah. — See *Bhang.*

Gunny Bags, Cloth, etc. — Gunny is the strongest coarse canvas or sackcloth in which pepper, ginger, rice, gums, and other tropical produce are generally shipped. Bengal gunny-cloth is made from *jute*, the fibre of the plants *Corchorus olitorus* and *Corchorus capsularis*, but another kind is made in Madras and Bombay from a variety known as sun-hemp. It used all to be made in handlooms by the natives—men, women, and children, boatmen, labourers, and domestic servants of all classes in their spare moments, but now the great bulk is made in steam factories. Gunny is largely manufactured from the imported jute at Dundee in Scotland. Both bags and cloth are also exported —new and clean—from India in very large quantities, say a hundred million bags a year.

Gunny bags weigh on an average about 2lbs. each, and gunny *cloths* are usually 30 yards long, and weigh about 6lbs. each.

Gunpowder.—Da. *Krudt, Pulver;* Du. *Buskruid;* F. *Poudre;* G. *Schiesspulver;* It. *Polvere;* Pol. *Proch;* Port. and Sp. *Polvora;* Rus. *Poroch;* Sw. *Krut.*

An explosive compound of sulphur, nitre, and charcoal. That made at the Royal Mills, Waltham Abbey, is simply a mixture of 75 parts saltpetre (nitre), 10 sulphur, and 5 charcoal. A better would probably be 75 parts nitre, 11·77 sulphur, and 13·23 charcoal.

Each substance is first purified and reduced to a fine powder; they are then put together, water added, and thoroughly well mixed. The paste is then generally pressed into small "pressed cakes," which after being dried are broken up and crushed between gun-metal rollers, then sifted and divided into the various sizes of grains. It is next glazed by friction, the grains being put into a bag, barrel, or machine, and subjected to a brisk shaking. This glaze is very important, for it afterwards helps to keep the powder from absorbing moisture, and to be moved about with less danger. The powder is finally thoroughly dried in a room heated to 100° Fahr.

Smokeless Powders.—The composition of these is kept secret by the various Governments, but one of the chief components seems to be *celluloid*, a substance obtained by boiling paper pulp with camphor.

When ordinary gunpowder explodes that which was solid is changed into gas, and requires about two thousand times more room, hence it drives everything out of its way, splits rocks, blows balls out of cannons, etc.

The powder used in big guns is queer-looking stuff. Each grain is a hexagonal prism, an inch wide and two-thirds of an inch thick, with a hole bored through the middle of it. In appearance it resembles a piece of wood. If you put a lighted match to it it will take seven or eight seconds to go off.

The manufacture, keeping, carriage, and sale of gunpowder are necessarily subject to numerous statutory regulations, which should be carefully read and remembered by dealers. No dealer is to keep more than 200lbs. in stock, nor any person more than 50lbs. within a mile of a market town or half a mile of a parish church.

Gunpowder Tea.—(See also *Green Teas.*)—The Chinese name for this is Yuen Choo (round pearls). Its English name is derived from its irregular lumps, which resemble the large grain of blasting powder. It is the finest kind of green tea, and consists of the early spring leaf buds, and particularly the fine hairy summits of the youngest branches of the shrub, which after being carefully picked are rolled and rounded by hand so as to have a granular appearance. One kind is known as *Moyune*, another as *Imperial*. Like other green teas, gunpowder tea is prepared from the same plant as black teas, but roasted immediately after gathering, and in another manner.

"*Shotty Gunpowder*" is a term applied to exhausted and spurious leaves rolled into gunpowder pellets, and given consistency and weight by a peculiar paste made for the purpose. Gunpowder teas possess about 52 per cent. of soluble matter. Half chests contain about 66lbs. each, and boxes 37lbs.

Gur or **Goor.**—A "compost" of cane sugar, used in India. It is very coarse and dark in colour, but very cheap, and suits the natives better than refined. It has a peculiar flavour, which is absent from machine-made sugars.

Gutta-Percha, although not a "gum" in a strict sense of the word, is a name derived from Gutta (gum) and Pulo Percha, the island where it was originally obtained. The *Percha Tree*, of the natural order *Sapotaceæ*, is a native of Singapore and other Malay Islands, where there are immense forests of these trees, the juice of which is obtained by tapping, and so yields us the invaluable *gutta percha.*

It was first discovered by Mr. Thomas Lobb in his botanical mission to Singapore and other Malay Islands, but was first sent to Britain by Dr. Montgomery in 1843 to the Society of Arts, which awarded him a gold medal. Below the temperature of 50° gutta-percha is as hard as wood, but rises with warmth until it becomes quite soft and pliable.

Gypsum or **Sulphate of Lime.**—Da. *Gibs;* Du., G., and Sw. *Gips;* F. *Gypse;* It. and Port. *Gesso;* Rus.

Ghips; Sp. *Yeso, Aljezon;* W. *Cymmryd-faen.*

Gypsum is a soft chalky kind of stone, or sublimate of lime, usually of a white colour, but sometimes grey, yellow, red, and, if very impure, brown or black. Found in France and various parts of the Continent, also in Derbyshire and Notts. It is extensively quarried at Stogumber and in Nova Scotia. It is very soft, and easily scratched. One kind, fine-grained, white, massive, and marble-like, is called *Alabaster;* another crystallised variety, transparent, and cleaving easily, is called *Selenite;* and a still more beautiful kind, with a fibrous and pearly opalescence, is known as *Satin Spar.* When reduced to powder and formed into a paste with water, gypsum is termed "*Plaster of Paris,*" being first introduced from that city. All these varieties are used for making ornamental articles, inlaid work, busts, necklaces, rings; also used by brewers for hardening water, etc.

H

Haberdine.—A name for dried salted cod-fish.

Haddock.—Da. *Kuller;* Du. *Schelvisch;* F. *Aigrefin, Merluche;* G. *Kabeljau, Schellfisch;* I. *Merluzzo;* Port. *Pescada;* R. *Vakhnya;* Sp. *Merluza;* Sw. *Kolja;* W. *Math o fôr-bysg.*

The haddock is a fish closely related to and resembling the cod, with similar arrangement of fins, namely, three dorsal and two ventral, also a similar barbule at end of lower jaw; but it may be distinguished by its smaller mouth, and its first dorsal fin is much more pointed. It has also a black mark down the back, and on each side of its body a round black spot, just above the fin and behind the gills. Some people aver these are the finger marks left by St. Peter when he took the pence from its mouth, but they do not explain what this salt water fish was doing in the fresh water of an inland lake!

The best haddocks are netted in large shoals in the deep waters off the East Coast, and the largest off Dublin. They are excellent fish when either eaten fresh or slightly salted and smoked.

"*Digby Chicks*" is a trade name given to the haddocks caught and cured at Digby Neck, a very pretty spot between Digby village and St. Mary's Bay, Nova Scotia. The fish are caught and brought right up to the factories, and handed out from the boats while still trembling. They are at once taken in hand by a number of men and transferred to what are called the fish-houses, where their heads are taken off and they are thoroughly cleansed, split open, and pickled clean, again washed and salted, and then put through that peculiar process which gives them the delicious flavour so much appreciated. They are then strung on long rods, dried for a few hours in the sun, hung in the smoke-house, and smoked with hardwood for fifteen to eighteen hours. After this they are transferred to the packing-house and cooked in a steam box, from whence they are slid into hollow tables covered with metal and taken in hand by the girls, who carefully bone and skin them and put them into the cans, which, when filled, are taken in hand by more girls, carefully weighed and washed, and passed on to the boy who covers them, whence they go into the hands of the sealers. As fast as the cans are sealed they are stowed in large bath pans and put into a tank, where they are steamed for a couple of hours, after which they are taken out and tapped, so as to let out the air that remains, and then re-sealed. Only indurated fibre vessels are used, so that no possible dirt can accumulate, and the flavour, cleanliness, and quality leave nothing to be desired.

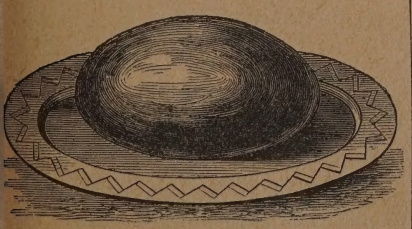
Finnan or *Findon Haddock* is

so named after the little fishing village of Findon, about eight miles south of Aberdeen, where haddock-smoking with peat has attained the greatest perfection. Elsewhere imitation Finnon haddocks are often prepared without the aid of smoke, the fish being merely washed in acetic acid and water and then hung up to dry. Enormous quantities are cured by London costermongers on the Surrey side of the Thames. Boys and girls are employed in beheading the fish, splitting them open, and scraping off all dirt, and then plunging them into tubs of brine; the fish soak there for about three hours, and then the skewering up process commences.

The larger haddocks are first one by one taken from the tub, and a peeled stick is passed through each fish until there are as many as the stick will hold. The smaller fish are treated the same way, and finally all are hung up in a little smoke-house, a fire is kindled on the ground and kept smouldering by a judicious application of sawdust underneath the haddocks. The whole process occupies only six or eight hours. In the wholesale markets fresh haddocks are usually sold 3/- to 15/- the trunk, 14/- to 20/- the "turn," or £20 to £30 the "machine."

A considerable quantity of frozen haddock is now exported in winter from Hammerfest, Norway, to Hamburg, for use in the North German garrisons, where, eaten with potatoes, it is very cheap food and well liked.

Haggis, Haggess or **Haggies.**—A popular Scotch dish made of the heart, lungs, and liver of the sheep, hashed or finely minced (about a quarter of the liver being grated), with suet, onions, oatmeal, salt, and pepper. The whole is usually sewn up in either the large stomach bag, or a smaller one called the "king's hood," of the sheep, well cleansed.



SCOTCH HAGGIS.

Burns wrote a fine poem on the haggis, calling it "Chieftain of the pudding race," etc.

Hair Dyes.—These are not so much used as formerly. They generally have lead or silver as their base, although the prejudicial effects of lead and silver salts have been so often pointed out by medical men.

Others are vegetable dyes guaranteed free from any mineral substance, but the profession seems to be divided as to whether these are innocuous or otherwise. Bismuth, pyrogallic acid, and certain astringent vegetable juices are also occasionally employed.

All those containing nitrate of silver are apt to stain the skin as well as the hair unless very carefully used. Hairdressers often smear hard pomatum over the adjacent skin near the hair to protect it from the dye.

Lead does not stain the skin, but does not impart the rich colour which silver produces.

Hair dyes are often the cause of severe headaches, local eczema, and other affections.

For materials apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Hair Oils.—F. *Brillantine.*

Various kinds of oil are perfumed and bottled for use as hair oil, and sometimes colour is added, the main objects being to get an oil that will keep transparent, thin, and free from objectionable smell.

Refined or debloomed petroleum and other oils are used when highly refined so as to be almost odourless, and these are often flavoured with either neroli, citronella, or cassia oil.

Seed oils, such as refined stettin or colza, are also extensively perfumed

with citronella, say half a teaspoonful for every pound of oil.

A fair oil is made from 15 gallons yellow cotton-seed oil, scented with 12 ozs. oil of lavender, 2 ozs. oil of thyme, and 4 ozs. oil of cloves; or it may be coloured with alkanet, steeping 2 or 3 drms. of the root in each pint of warm oil till coloured to shade desired, and scented with 8 ozs. oil of bergamot, 6 ozs. oil of cassia, 4 ozs. oil of cloves, and 1 oz. white oil of thyme; or a good hair oil is produced by taking a gallon of refined mineral oil and adding 2 ozs. of citronella and 1 oz. of oil of bergamot.

One gallon will fill a gross of ounce bottles.

Hair Powders.—These usually consist of starch or potato flour reduced to a very fine powder, and then scented with a few drops of essential oil of roses, violet, or other perfume, according to fancy.

For materials apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Hair Restorers.—Perhaps the most satisfactory preparation is simply an odourless and colourless non-viscid petroleum, of specific gravity between 0·865 and 0·870. This, suitably coloured and perfumed, say with lemon oil or oil of citronella, gives a hair restorer which is really efficacious. It acts both as a germicide and as a stimulant to the hair.

Hake.—A fish of the cod family, sometimes called *Herring Hake* or *Stock-fish*. It is a coarse quality, of whitish colour, with grey on the back. Mostly caught by lines on the Atlantic coasts at the North of Europe and off Nova Scotia.

Hakes are 2 to 4 feet long, with broad flat head, the mouth very wide, and the lower jaw extending beyond the upper. Of its two dorsal fins the first is small and triangular, while the other extends to half the length of its body, and its anal fin (of same shape and size) is exactly opposite.

The hake is very voracious, feeding chiefly on herrings and pilchards.

Its flesh is somewhat coarse, and not much esteemed; but it is always cheap, and large quantities are salted and dried.

Halford's Curries.—So called after Mr. Halford, once *chef* to Lord Dalhousie when Governor-General of India.

Halibut or **Holibut.**—W. *Lleden y mor*.

The largest species of the flounder or flat fish family, measuring 3 to 6 feet long, and weighing up to 100lbs., 200lbs., and even 500lbs. each.

Its two eyes are both on the right side of its head. Mostly caught by hook and line off Greenland, Norway, Scotland, and similar northern latitudes. After being caught they are often kept alive six or eight weeks by being packed in large perforated boxes, which are sunk or floated in a dock or other shallow water.

Usually sold wholesale by the *stone*, price 5/- to 10/-.

A very reprehensible cruelty prevails among fishermen and others of hanging up these fish alive by the tail. They are often so held until the pressure actually cuts through the softer parts, leaving the bone exposed.

The flesh is white and firm, but rather dry and coarse; the fins and flaps, however, are considered tender and delicate. (See *Soles*, *Plaice*, etc.)

Besides being cooked and eaten fresh, it is salted, dried, and smoked. Halibut is often sliced up and pickled in barrels.

Hall's Hair Renewer.—Precipitated sulphur, 1 drm.; acetate of lead, 1 drm.; common salt, 2 drms.; glycerine, 8 fluid ozs.; bay rum, 2 fluid ozs.; Jamaica rum, 4 fluid ozs.; water, 16 fluid ozs. Shake well before using.

Ham, Potted.—This is generally expected to be prepared from the Westphalian ham, the flavour of which is so highly esteemed by *connoisseurs*, Like other *Potted Meats* (which see),

it is highly seasoned, and intended as a relish.

Hams. — Du. *Hammen;* F. *Jambons;* Ger. *Schinken;* It. *Prosciutti;* Port. *Presunto;* Sp. *Jamon.*

These consist of the thighs of the pig, salted, smoked, and dried, or otherwise cured; but sometimes, rightly or wrongly, the shoulders are carved out to represent hams, and sold as "*Pic-nic Hams*" at a low price.

In England the most noted counties for fine hams are Yorkshire, Cumberland, Wiltshire, and Hampshire. The Devonshire long-cut hams—smoked or pale dried, and produced in the district round Plymouth—are also highly popular.

Those of Westphalia (see *Westphalian Hams*) and Portugal are highly esteemed on account of their exquisite flavour.

Mayence, Hamburg, and Stuttgart are each celebrated for hams. In Paris the *Foire aux Jambons*, held in Lent, is one of the most ancient, popular, and successful of French fairs. During the three days it lasts the sales amount to many hundreds of tons.

The ham of Bayonne owes its fame to the chestnuts on which the pigs feed. The *petits jambons vermeils* of Montanches are from porkers fed on chestnuts and snails.

Of English hams, those which are short in the hock are considered best; a sharp knife or skewer pushed under the bone should have a pleasant smell when withdrawn.

Smoked Hams have a strong taste, and are more fitted for a relish than for diet, and they should be particularly avoided by the dyspeptic and by convalescents.

Old hard hams should be soaked for about twelve hours before cooking. In boiling hams they should always be put into cold water, and *gradually* heated. A 14lb. ham requires about 4 hours, 16lb. 5½ hours, and a 20lb. ham will take about 6½ hours to dress it properly. (See *Smoked Meats.*)

American hams are now mostly cured in salt and then packed in borax. They come to England in boxes of about 5 cwts. When unpacked they are washed and dried, or scraped and smoked. If it be desired to put a nice clear skin upon them, to show well, they are dipped in hot water until the skin is softened, and are then scraped. During this operation the original brands are often obliterated, and sometimes other marks are substituted.

One of the curious businesses that men engage in is ham-smelling in packing-houses. It is a business allied with that of tea-tasting, wine-testing, and the like. The ham-smeller is technically known as ham-tester. It is his business to inspect meat products and judge of their soundness. This is done before the meats leave the house, or when they are brought from other concerns to fill a shortage.

The ham-smeller's only tools are a long steel trier and his nose. It is often necessary to test hams after they come out of the sweet pickle and before they go into the smoke-house. The ham-smeller stands in a barrel to keep his clothes from being soiled by the dripping brine, and the hams are brought to him by workmen. A ham is laid before him and he plunges his sharp-pointed trier into it, withdraws it, and places it swiftly beneath his nose. The trier always goes down to the knuckle joint. In testing meat in that manner the man with the trier judges by the slightest shade of difference between the smell of one piece of meat and another. The smell of the meat is almost always sweet, and that is what he smells; the slightest taint or deviation from the sweet smell is, therefore, appreciable. It is not the degree of taintedness that he expects to find, but the slightest odour that is not sweet. When he detects an odour he throws the meat aside, and if it is not unwholesome it is sold as "rejected" meat, but if it is tainted it goes to the rendering tank. The ham-tester smells meat from seven o'clock in the morning until five o'clock at night, and his

sense must never become jaded or inexact, or his usefulness would be at an end.

Ham-testing is not a pursuit dangerous to the health, as tea-tasting is supposed to be, but the ham-smeller with a cold in his head is like a piano player who loses his arm in a railway wreck.

Flies.—To protect hams from those troublesome little flies, *Dermestes lardarius*, which lay their eggs in the hams and soon fill them with maggots, it is best to brush the hams over with a little pyroligneous or acetic acid, of ordinary commercial strength. In fact, acetic acid is now largely employed in factory-cured hams and bacon, fish, etc.

Procure some cheap muslin, about 1d. or 2d. a yard, and cut it in pieces large enough to cover the face of the ham, and extend in every direction an inch over the rind. The part that extends over the rind may be covered with common paste, and attach it to the rind, taking care that the muslin adheres properly. Care should also be taken that the muslin is drawn tight over the face of the ham, when the projecting parts will keep the muslin away from the crevices, where the fly is only too fond of laying its eggs. By this plan fifty hams may be covered for less than 1/-.

Recipe for Sugar-Curing Hams.—As soon as the meat comes from the butcher's hand rub it thoroughly with salt, and repeat this four days, keeping the meat where it can drain. The fourth day rub it with saltpetre and a handful of common salt, allowing 1lb. of saltpetre to 70lbs. of meat. Now mix 1lb. of brown sugar and 1lb. of molasses, rub over the hams every day for a fortnight, and then smoke. Hams should always be hung highest, because they are then less liable to the attacks of insects.

Another recipe says the brine may consist of 45lbs. salt, 5lbs. borax, 4lbs. sugar, and 3lbs. saltpetre to every 20 gallons of water.

Cooked Ham has lately become a salable adjunct to the grocery trade in some localities, and there is a tendency on the part of two or three firms to limit the business to proprietary brands; but it is to be hoped that retailers will have the good sense to decline this idea, and boil the hams themselves as required.

Why should a grocer fetter himself by introducing other peoples' brands so unnecessarily?

How to Boil a Ham.—Soak it in cold water from six to twelve hours; place it in a kettle, and cover it with cold water; bring it very slowly to a boil; remove the scum, and simmer it softly, allowing about 4lbs. to the hour, until the skin can easily be removed. After taking off the skin replace the ham in the liquor, and leave it there until it has become cold; then rasp it in the usual way, and brown it off in the oven. If the ham be not probed or cut it will retain all its juices and be very mellow.

Apply to *Hillier's Bacon Curing Co., Ltd.*, Newmarket, near Stroud. (Three Prize Medals.)

Bologna Sliced Ham.—Bologna hams, like Bologna sausages, owe their celebrity to the plentiful growths of chestnuts and acorns in the immense forests where the pigs feed. It is not, however, sufficiently well known in this country that the famous Bologna ham may now be had ready cooked and sliced, in small flat oval tins of ½lb. each.

There are several packers and probably several qualities, but the original and by far the most celebrated brand is that of Fratelli Nanni, of Bologna. In their tins we have ham of exquisite flavour and quality, nicely cooked, and beautifully sliced, ready for eating either in sandwiches or otherwise.

Travellers and others at home and abroad who have so often been disgusted with the flavourless and insipid American ham (and hams nowadays are mostly American) will fully appreciate this great improvement.

Already many householders find it both convenient and economical to keep a few tins of really good ham in their

larders ready for any emergency. Each tin has a key attached, and is easily opened without disarranging the contents, which latter are found quite as fresh and appetising as the best newly-cut ham.

Retailers would do well to apply to Prevet & Co., the sole importers, 134 Fenchurch Street, London, E.C., for samples and prices.

Hankow Teas.—These Chinese teas have deteriorated and suffered much in repute these last few years.

There are several establishments in Hankow where teas from other districts are refined and prepared for export to foreign markets.

Hard Fish.—A general term for salted and dried or smoked fish, such as cod, hake, ling, and other stock-fish.

Hares. — F., Port., and Sp. *Lièvres;* Ger. *Hasen.*

The hare is a mammel of the *Rodentia* or gnawing order, and there are several species, but they all have four incisors in the upper jaw, with two small square teeth behind them, five or six molars in the upper jaw and five in the lower.

Hares are found all over the world, except Australia. They are mainly night-feeders, each one making its own couch in a tuft of grass or other herbage. They dislike and fight rabbits whenever they meet.

The flesh of those from hilly districts is best; those reared in low damp lands are not so good for eating. A young hare during the first year of its growth is termed a *leveret.*

A full-grown English hare is about 27 inches long and a foot high, and weighs 13 to 20lbs.

Haricot Beans. — F. *Haricots, Fayots;* Ger. *Weisse Bohnen;* Port. *Feixoes;* Sp. *Habichuelas Secas, Aluvias.*

The white haricot bean (*Phaseolus vulgaris*), or *Haricot Blanc* of the French, is a native of India; and although it will grow wherever other beans will grow, yet its cultivation is mostly confined to France, Germany, Italy, and Switzerland, from which countries they are exported to the English markets.

The *Scarlet runners* or *French beans* of our English gardens are climbing varieties of the same family, but are usually gathered and cooked while green and immature in this country.

The large and floury variety known as *Haricots de Soissons* are the finest, and are grown around the town of Soissons, in the Aisne Department of France. Another white variety, *Liancourt,* grown in the district of that name in Oise, are of flatter form, drier, and firmer, and less liable to burst in cooking.

The *St. Esprit Haricot* is also a white sort, and so called from two small marks vaguely resembling a dove, the symbol of the Holy Ghost.

The other white haricots are *Suisses blancs, Flageolets blancs, Flageolets verts* or *Chevriers, Nains, Gros pieds, Lingots,* etc. (*Soissons* and *Chevriers* are always highest priced.)

Among the red and variegated coloured are the Chartres, *Suisses rouges, Cocos roses,* etc.

Haricots Riz (or rice haricots) are, as the name denotes, a small but very prolific variety, and somewhat floury.

Haricots are usually sown late in April, and cultivated same as field peas. When the pods are well filled and begin to turn yellow they are ripe, and the plants are then pulled up, dried, and thrashed like peas.

There is, perhaps, no other vegetable dish so cheap and so easily cooked, and at the same time so agreeable and nourishing. Haricots merely require soaking for about twelve hours, boiling, and then mixing with a little fat (or salt butter) and a little milk (or flour and water). To avoid bursting them, boil slowly.

The white skin-coverings in which the inner seed lobes are enveloped should not be eaten by delicate persons, as that tough substance is most indigestible, even in young beans.

Of red haricots there are the *Ordinary* and the large *Spanish*, of red, violet, and white or grey colour; but these (*Haricots du pays*) are grown more as ornaments for gardens, their beautiful white and red or streaky flowers being universally admired.

As a substitute for animal food during Lent and other fast-days haricots have long been highly popular, especially in Roman Catholic countries, and their use in England in days gone by was considered a sure sign of "Popery."

In a dried state they should be chosen of uniform size, large, firm, and full, with the skin smooth and white.

They sell best in cold weather and between the potato seasons, when old potatoes are getting out of condition and new ones are dear.

(A table of weights and measures of haricots will be found under *Peas*.)

Haricots Flageolets.— See *Flageolets*.

Haricots Verts (*French Beans*).—G. *Grüne Bohnen*.

Haricots Verts (green haricot beans), in pod, come from France, preserved in bottles or tins, 50 or 100 to the case, and are classed and quoted as *mi-fins* (large), *fins* (small), *très fins* (very small), and *extra fins*—the largest growths being lowest and the least or youngest the highest in price.

Apply to J. A. Sharwood & Co., Ltd., St. George's House, London, E.C.

Harlequin Soap.—This ordinarily consists of variously-coloured soaps, which (having been made separately) are cut into lumps of suitable size and are then stirred up in a liquid cold-process soap which is more or less transparent. When cold and set the mass is cut into blocks, stamped, and polished, and packed in ornamental boxes.

Harmless Colours.—See *Colours for Foods*, etc.

Harness Blackings.—(See also *Blacking*, *Liquid Blacking*, and *Shoemakers' Black*.)—For cleaning all kinds of black leather harness, carriage headings, aprons, etc. Recipe:—8 ozs. beeswax softened with 1 oz. turpentine, adding 2 ozs. ivory black, 1 oz. Prussian blue, and ¼ oz. copal varnish. It is applied with a brush, and may be polished with a duster.

The word "harness" is from the old French word "*harnois*," the armour of a soldier, which used to be fastened on with straps and buckles.

A good harness blacking is also made by melting 2lbs. beeswax, and then adding 10 ozs. bone-black, 4 ozs. Prussian blue ground in oil, 4 ozs. oil of turpentine, and 2 ozs. copal varnish. It should be well mixed and formed into balls.

Another is made with isinglass or gelatine and indigo, say ¼ oz. each, 4 ozs. logwood, 2 ozs. soft soap, 4 ozs. glue, and 1 pint vinegar. These are heated, mixed, and strained.

Harness Composition:—

Ordinary constituents	Parts by Weight.
Beeswax (best yellow) ...	90
Spirits of turpentine	900
Animal charcoal (ivory black)	50
Indigo	5
Prussian blue	10
	1055

Melt the wax in a suitable vessel, reduce the other ingredients to the finest possible powder, intimately mix them in the dry state, and stir into the hot solution of wax in spirits of turpentine. Cool gradually with constant stirring, and pack into boxes for sale.

Special Manufacturers.—Day & Martin, Ltd., London and Liverpool. (See advt. near end of book.)

Harness Polish.—A good one is made from 4 ozs. of glue, 6 gills of vinegar, 2 ozs. gum arabic, 2 gills of black ink, and 2 drms. of isinglass. Break the glue in pieces, put it in a dish, pour over it about three parts of the vinegar, and let it stand till quite soft. Dissolve also the gum in another vessel with the ink, and let the isinglass

melt near the fire in as much water as will cover it. When all are ready pour the rest of the vinegar into the softened glue, and place it on a stove or over a moderate fire, stir it till hot and thoroughly dissolved, but do not let it reach boiling point; then add the gum and stir again till hot and well mixed, and finally add the isinglass in the same way.

For use, warm a little as required in a saucer till it becomes liquid, and apply a thin coat with a fine brush or sponge and dry quickly.

For materials apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Hartshorn. — F. *Corne de Cerf;* G. *Hirschhorn;* Lat. *Cornu cervi.*

This consists of the horns of the male deer without further preparation. The chemical analysis of hartshorn is sufficiently known; it yields a water highly impregnated with a fetid oil and volatile salt, by the common distillation in a retort on an open fire. The remainder in the bottom of the retort, after the distillation is finished, is black, but in calcining it in an open fire it becomes white and friable, and is then sold under the name of *burnt hartshorn.*

Harvey's Sauce.—It is said this sauce was first compounded in 1795 by a person who sold the recipe to Elizabeth Lazenby, under whom the sauce acquired the name of *Lazenby's Harvey's Sauce,* but in the Rolls Court, 1870, it was decided that other parties had also a right to make and sell Harvey's Sauce, provided they did not colourably imitate Lazenby's label.

A modern recipe:—2½ gallons walnut ketchup, 2½ gallons mushroom ketchup, 3½ gallons soy, 1¼lbs. garlic, 7½lbs. sprats, ¼lb. cayenne pods. Boil twenty minutes, stir, cool, and strain.

An excellent Harvey is now made by Allen Jeeves & Sons, Seddington, Sandy, Beds.

Hasheesh or **Hachshisch.**— See *Bhang.*

Haut-Brion Wine is esteemed one of the best of the *Vins de Graves* in the Gironde department, France. The bouquet savours of the violet and raspberry, and the flavour of burning sealing-wax.

The estate of Chollet, where it is produced, is the property of the French Government, and comprises about 58 acres. The wine is not bottled until six or seven years after vintage.

Hay Spice.—A mixture of aromatic herbs, spices, and roots. Intended to utilise damaged hay by perfuming or flavouring it, so that animals will eat it. Sold freely to farmers and others.

Hazel Nuts.— Da. *Hasselnodder;* Du. *Hazelnooten;* F. *Noisettes;* G. *Haselnüsse;* It. *Naccinole, Avelane;* Pol. *Loskowy Orzeck;* Port. *Avellaes;* Rus. *Orechi;* Sp. *Avellanas.*

Hazel Nuts comprise several varieties:—Kentish Cobs, Filberts, and Barcelona nuts.

These are the fruit of the hazel, *Corylus Avellana,* a supple underwood, bush, or small tree, of a hardy and deciduous character, so named from Avellino, in Italy, where they were first cultivated. There are about a dozen species, the chief being known as the white and red *Filbert,* the large and clustered *Cob,* and the *Barcelona* (vars.: *ovata, pumilla,* and *variegata*), as imported from Tarragona, all improved from the common hazel nut.

The best and plumpest nuts come from Piedmont, but very good ones also come from Sicily, the latter being quite equal in *appearance* and much lower priced.

Cadière nuts, or *Acadières,* grown near Toulon, in France, are another highly popular kind.

These small nuts are considered more nutritious than walnuts; the kernels have a mild farinaceous oily taste, agreeable to most palates, and the oil expressed from them is very little inferior to the oil of almonds. In France they are often eaten while quite green.

Hazel-nut-Oil has long been considered very valuable for watches and other delicate machinery.

Hazel Sticks as Divining Rods.—An absurd notion prevails in some districts that the whereabouts of water-sources, hidden treasures, etc., can be ascertained by sticking leafy hazel shoots or suckers in various parts of the ground, and noticing the subsequent changes in their foliage.

Hazel-nuts grow in most of the temperate climates, but attain the greatest perfection in Spain and Southern Europe. They are all subject to the ravages of a weevil, called *Bolaninus nucum*, which bores a hole into the nut and lays its eggs in the kernel, large quantities being thus rendered useless by the young larvæ. It is therefore necessary for the nuts to be kiln dried in order to keep them sweet and good.

Heading or **Froth.**—See *Foam.*

Hearthstones.—A soft calcareous kind of sand-stone, obtained chiefly at the Godstone Quarries, in Surrey.

Used for glass furnaces, backs of fireplaces and stoves, and for scouring stones, cleaning hearths, etc. For the latter purposes the stones are sold in squares at about 8d. a dozen wholesale.

Heelball.—A hard black waxy substance, employed to impart a black polished surface to the heels and soles of boots, also to harness. It is composed of indiarubber, and the black residue left in the still when refining ozokerit for candle making.

Hemp seed.—F. *Chènevis;* Ger. *Hanfsaat;* It. *Cannapuccia;* Port. and Sp. *Linnaca;* Rus. *Konoplijanoe semja.*

This is the seed of the common hemp plant, an annual which grows from 2 to 20 feet high in rich land in most parts of the world. It is of the same family as the nettle, but is readily injured by frost. The plant is, however, chiefly cultivated for its valuable fibre, which is made into ropes, canvas, sailcloth, etc. Large quantities are grown in Manila, but the best hemp (known as *Henequen fibre, Sacqui, White,* or *Sisal hemp*) is grown in Yucatan, in the east of Mexico, the annual exports reaching about 350,000 bales a year, each bale weighing about 375lbs.

Another kind of hemp, known as *Phormium*, is grown in New Zealand.

Hemp-seed is used as food for cage birds, fancy fowls, etc., and also for crushing for oil. It is said that the plumage of bullfinches and goldfinches fed on it too much changes from red and yellow to black. There are several varieties and sizes of these seeds, and one large size is known as *Parrot-seed.*

Oil of hemp-seed is a fixed oil of a greenish yellow colour, and is largely used in Russian cookery. In tropical countries both the seed and the plants develop powerful narcotic properties. The Scythians were accustomed to intoxicate themselves with a preparation from hemp-seed, as the Hindoos do now.

The Indian hemp plant yields (1) *Ganja,* an extract secreted on the female flowers, and which is smoked; (2) *Bhang,* the dried leaves; (3) *Majun,* a substance employed in preparing the intoxicating beverage known as *Hashish,* and various intoxicating sweetmeats.

In choosing hemp-seed select the brightest and toughest—that which will not break readily when rubbed.

A quarter of Riga or Dutch weighs about 336lbs.

Special Firms.—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool; Hedley, Gamble, & Crosfield, Circus Street, Liverpool.

Wm. Gardner & Sons, engineers, Gloucester, make machines specially suitable for treating above. Catalogues free.

Herb Beer.—See *Non-Alcoholic Beers,* also *Extract of Herbs.*

Herbs.—See *Dried Herbs.*

Herb Teas.—These are made in a variety of ways, either by mixing a number of herbs together or by using one herb only. Some kinds are more or less poisonous if taken too strong or to excess—hence the sphere of the pro-

fessional herbalist, who professes to have studied the intrinsic value of each particular herb. The medicinal value attributed to herbs is not nearly so great now as it was two or three hundred years ago.

Sage Tea is considered to possess valuable aromatic and astringent properties, and is also useful for debility of the stomach and in nervous cases.

Mint is stomachic and antispasmodic. The peculiar flavour and properties of *Peppermint* are chiefly owing to the camphor which that plant contains, and of which one-fourth of its essential oil is composed.

Pennyroyal, which belongs to the mint family, has long been known to be valuable in female diseases.

Clary Flowers form the basis of a medicinal wine. (See *Clary*.)

Tansy Tea is good for colic and gout.

Fennel Leaves, made into tea, are diuretic in their tendency, and the root is aperient.

Dillwater relieves wind and indigestion, and is frequently given to infants.

Marigold Flowers form a tea good for promoting perspiration and strengthening circulation, also good for liver complaints.

Rue, or the "herb of grace," is a stimulant anti-spasmodic, increases the secretions, and excites the circulation.

Hyssop.—The leaves and flowering tops, made into tea, form a gently stimulating aromatic; also good in chronic catarrhs and disorders of the chest and lungs; often applied externally to restore the natural colour to the skin after bruises. It is an important ingredient in making Absinth, and imparts the green tinge, but is considered the most injurious factor in that baneful compound.

Rosemary Tea is a tonic and a cordial, stimulates the circulation and nervous system, and is often a cure for headaches. Sometimes the powdered leaves are taken in the form of snuff.

Balm Tea is a favourite drink in cases of fever.

Camomile Tea is a powerful aromatic bitter and a fine tonic.

Herb Tobaccos.—Composed chiefly of dried coltsfoot leaves, mixed with a little thyme, wood-betony, eyebright, and rosemary—say 6 parts coltsfoot with 1 part each of the others—all cut up fine, and well mixed.

Hermitage Wines.—F. *Ermitage*. These are some of the finest wines France produces. There are both white and red varieties, divided into five classes, of which *Ermitage Paille* is the choicest, although they are usually dry, nutty, strongly vinous, and of deep purple colour.

They are grown in the Rhone valley, near Tain, and derive their name from an old hermitage on the summit of an adjacent hill.

Herrings.—Da. *Sild*; Du. *Haringen*; F. *Harengs*; G. *Haringe*; It. *Aringhae*; R. *Selyodki*; Port. and Sp. *Arenques*; Sw. *Sill*; W. *Ysgadan*.

The herring, species *Clupea harengus*, is the commonest and most important class of fish that visits our shores. The word herring is derived from the Dutch word *herr*, an army. It is essentially a northern fish, and is found in the highest latitudes, but not further south than the North of France, their great home and rich feeding trough being within the Arctic Ocean. Early each spring the mighty herring family begins to prepare for a southern outing to warmer climes for spawning purposes, and in April or May the advance columns are anxiously expected off the North of Scotland, to be followed in a month or so by an enormous army, often six or seven miles long by three or four wide, arriving at Wick in June or July, Peterhead and Aberdeen in July or August, and Yarmouth and the Kentish coast in August or September. The Shetland Islands seem to split the shoals in two, and they invest, more or less capriciously, nearly every bay and creek round the British Isles, as well as all other similar geographical positions of Asia and America.

The herring fishery is more valuable than any other save the cod, and the first arrivals of the fish once witnessed will never be forgotten.

The sea for miles round shines with a silvery lustre from their glittering scales, for the herring swims near the surface with its nose out of the water, as though enjoying the fresh air, and the effect is very peculiar. The myriads of little fish rushing along seems to affect the very sea itself, making a loud soughing noise, like a heavy fall of rain, the result of the rippling caused on the surface of the water. These great herring armies are also accompanied by various larger fish, gannets, hawks, gulls, and other sea birds, all of which feed on the herrings. Considering these and the raids made everywhere by fishermen, it is not easy to imagine how the brave little survivors—weakened, worn, and harassed—ever reach their icy home again; but each spring the herring shoals come afresh, plump and fat, and although the season may occasionally vary at different points, yet the supply never appears seriously to diminish, nor even to require cultivation. Grimsby is a great herring port, and the weight sent off per rail from that town often amounts to 1,000 to 1,500 tons a week. The prices fluctuate extremely. Sometimes they are sold as manure, but usually good hard fish sell at £6 to £8 per last; "mazy," or "full," and "oily" qualities rarely fetch more than £2 to £4. Much also depends on the weather being wild or fine, strong gales often preventing the fishing boats getting to sea at the best time. There are divers measures. An ordinary *cran* is 37½ inperial gallons, and contains about 800 mature or about 1,000 immature herrings; a *barrel* contains rather less.

On the east coast of Scotland from Shetland to Berwick, also at Castle Bay and Stornaway, they are sold by the cran of 26⅔ imperial gallons; but on the west coast, Isle of Man, and in Ireland by the maze, which contains five long hundreds of 123 each. On the east coast of England they are sold by the last, which contains 13,200 fish. They are counted by the warp, which is 4; 33 warps equal one long hundred, 132; ten hundred equal 1,000, 1,320; ten thousand equal one last, 13,200.

One of the principal herring fisheries of Ireland is at Ardglass, where a fleet of over 300 boats finds ample employment. As much as £4,000 of fish has been taken in one night.

Herrings never go up rivers to spawn. Each female appears to produce some 10,000 eggs in a season. A young herring grows at the rate of about one-third of an inch a month, and matures at two years old, but is not even then full grown. They are said to feed on crustacea and other small pelagic organisms.

"Full fish" is a trade term applied to the second class of herrings when the roes and milt are largely developed. After spawning they are termed "spent fish."

It has been calculated that a single pair of herrings, if allowed to reproduce undisturbed and multiply for twenty years, would not only supply the whole world with abundance of food, but would become inconveniently numerous.

Herrings are marketed and treated in a variety of forms. (See *Fresh Herrings*, *White or Pickled Herrings*, *Kippered Herrings*, *Red Herrings*, *Bloaters*, *Bloater Paste*, etc.)

Hickory-nuts.—The fruit of *Carya alba*, and chiefly imported from the United States.

High Caste Ceylon Tea, and Silver Packet Teas.—Agents wanted in districts where not yet represented. Show cards, etc., with first orders, bill heads, hand bills, memorandum forms, posters, and a variety of printed matter supplied at frequent intervals. Illustrated almanacs free of charge in December. Only one agent in each town.

Write for particulars to Spencer,

Turner, & Boldero, Limited, Lisson Grove, London, N.W.

Hipi. —"Hipi" is Maori for sheep, and is also the name given to a Mutton Extract manufactured in New Zealand from fine mutton.

Hippocras.—A spiced wine, based on ginger, cinnamon, and Grains of Paradise.

Hock or **Hochheimer.**—The name of *Hock* is now commonly applied to any white German or Rhine wines, but the true Hochheimer is grown to the eastward of Mentz (Mayence) between there and Frankfort, especially around Hochheim, and is mellowed best in large vessels such as the famous Heidelburg Tun, which will hold some 600 hogsheads.

It is a wine of exquisite flavour, with about 7 per cent. of absolute alcohol, and may be either "still" or sparkling.

Sparkling Hock is made in the same way as Champagne, and is often sold for it. Probably the finest brands are the Hochheimer "Domdechanei," but there are many commoner and lower-priced brands. Hochheimer wine is very popular in Germany as the working man's beverage, and the flavour is fancied to be improved by drinking it out of thin green glasses.

"Cape Hocks" are produced in the village of Paarl, Cape Colony, and are considered to be the best dry wines of Africa.

Hodge-Podge. — See *Hotch-Potch.*

Hoe-cake.—See *Maize Bread.*

Hog-nuts. —The fruit of *Carya porcina,* chiefly grown in Canada, but not often met with in trade.

Hokey-Pokey.—A flash name for a cheap sweetmeat, often sold in the streets, country fairs, etc. It is usually made from the common Neapolitan ice-creams, which, after being moulded into small brick-shaped squares, are re-frozen and wrapped in papers.

Sometimes hokey-pokey is made by boiling white sugar to a candy, colouring it pink or white, and then cutting it into squares about ¾ oz. or 1 oz. each.

Hollandaise.—A rich fat sauce used chiefly with hot boiled fish.

Holder's "Victorian" Raspings. —For Fish, Rissoles, Cutlets, etc. This special preparation is far superior to bread-crumbs, so generally used, and should be invaluable to chefs and housekeepers generally.

Agents wanted. Sole Manufacturers. —W. Holder & Co., Woodbridge, England.

Holland's Gin.—Du. *Genever;* F. *Genièvre;* G. *Gaud, Genever;* It. *Acqua di Ginepro;* Port. and Sp. *Ginebra.*

Also known as Schiedam, Geneva, or Dutch Gin. These are all rich, soft, oily, mellow, and aromatised varieties of gin. The best is made at Schiedam, in Holland, and exported to this country both in cask and in old-fashioned, dark-coloured square bottles, which are usually packed in cases with hemp husks. Hollands gin is generally made from two parts of the best unmalted rye, one part of malted bigg, ground to a coarse meal and highly flavoured during rectification with juniper berries. The distillers most noted for Hollands add a little pure Strasburg turpentine and a handful or two of hops to the spirit along with the juniper berries before rectification.

At Rotterdam sweet fennel seed is commonly added, while at Weesoppe, Strasburg turpentine and fennel seeds or essential oil of fennel, are often substituted for a large portion of the juniper berries.

To see Dutchmen absorb Genièvre visitors to Amsterdam should look in at the grand café "*Kratznapolski*" between 5 and 8 p.m. and see the long ranges of tables crowded with customers, smoking their cigars, and methodically and slowly sipping their "Schnaps" (strength 40 to 50°), adding a little white powdered sugar, but not water. The sight, the smoke

and the noise would never be forgotten.

But Schiedam is the metropolis of production, the Mecca of the Dutchman, and the birthplace of his beloved "Schnaps"!

The omniverous distilleries of that little town take with equal relish whole cargoes of rye and buckwheat from Russia, and damaged rice or any cereal from other countries, as well as potato spirit from Hamburg.

A manufactory for "Hollands" was started some years ago at Maidstone, in Kent, but it only languished a few years, and ended in bankruptcy.

Hollands gin when genuine is considered superior to English gin, and is said to owe much of its peculiar flavour to the different way in which it is made, the malt, juniper berries, sugar, and flavouring ingredients, all being mixed and fermented together before the distillation is effected—whereas this is not allowed in England.

Plymouth gin somewhat closely resembles "Hollands," but Schiedam Hollands, usually six overproof, are considered the best, then come those of Rotterdam, and after these, Weesoppe Hollands. Concentrated flavouring essences for making these gins are sold by wholesale druggists, etc.

Holloway's Ointment. — The original formula of *Albinolo's Ointment*, of which this pretends to be a reproduction, contained "serpent and viper grease" and other similar curiosities. The principal ingredients, however, in *Holloway's Ointment* of the present day are more homely substances, and a few years ago, in France, where the sale of such secret remedies is prohibited, it was analysed by the authorised Government chemist, and was found to contain "butter, lard, Venice turpentine, white wax, yellow wax, and nothing else." In a letter to *The Times*, Mr. Holloway afterwards stated that this French analysis was incorrect. It has, however, often been noticed that no two samples of the "ointment" are precisely of the same colour or consistence.

Holloway's Pills.— These have been examined, and said to consist of aloes, 4 parts; jalap, ginger, and myrrh, of each 2 parts; made into a mass with mucilage, and divided into 2-grain pills, of which about 4 dozen are put into a 1/1½ box. Another analyst says 144 pills contain 62 grains of aloes, 27 grains of rhubarb, 3 grains of saffron, 3 grains of Glauber's salts, and 7 grains of pepper.

It is said that these famous pills were the result of a recipe given by an old German woman to the late Mr. Thomas Holloway's mother. They were a failure at first, and their youthful manufacturer was thrown into prison for debt. When he got out he started a shop in the Strand, began advertising, and never looked back.

Holly.—(See page 232.)

Holy Oil. — Oil blessed for ritual use in the Primitive Church, and still used in the Roman Catholic and Greek churches. There are three kinds:—*Oil of Catechumens*, used to anoint candidates before baptism; *Oil of Chrism*, a compound of oil with balsam or with wine and aromatics, used at baptism, confirmation, coronation of sovereigns, etc.; *Oil of the Sick*, used at the unction of the sick, and which (in the Greek Church) has been in contact with a relic or other sacred object, or has been taken from a church lamp.

Hominy, Corn Grits, etc. — A popular American food made from white Indian corn or maize.

The name is from *Auhuminea*, the North American Indian word for *parched corn.*

The maize is hulled and split and more or less coarsely ground and sifted. It is afterwards prepared for the table by adding milk or water, and boiling, when it may be formed into excellent puddings, cakes, or a summer porridge, and is not so heating as oatmeal. It is a very cheap article and highly esteemed throughout the United States. In England it is

usually retailed in 5lb. linen bags at 9d. to 1/- each.

Homœopathic Cocoa. — A name originally obtained by Epps's Cocoa, simply because of Mr. Epps, the manufacturer, being a well-known homœopathist—in fact, the first Homœopathic Chemist established in this country.

The name has, however, since been appropriated by other manufacturers of cocoa, who, ridiculously enough, have not the remotest connection with homœopathy.

Hones, Rag, or **Whetstones** (see also *Oilstone*) are pieces of smooth-surfaced stones, used for sharpening implements, tools, cutlery, and instruments that require a delicate edge. There are several kinds, the finer of which are a sort of silicious slate, and when used are moistened with oil or water. The *Staffordshire Oilstone* is a popular whetstone, and to prevent it being broken it is usually set in a piece of wood and provided with a wooden lid to keep off dust and dirt.

Turkey-stone, or hone, imported from Turkey, is of a greenish colour and a coarse grain, and best adapted for carpenters' tools, common knives, etc. The finer varieties are often called Turkey slate.

The *German Hone* is a softish yellow stone of a finer grit, obtained from the slate mountains near Ratisbon, and used chiefly for razors, surgical instruments, etc. Both the latter kinds have a smaller grain and more compact texture than the British whetstone. Ragstone is a provincial word for any hard, coarse-textured rock.

Honey.—Da. *Honning;* Du. and G. *Honig;* F. and Sp. *Miel;* It. *Miele;* Per. *Shahud;* Port. and W. *Mel;* Rus. *Meod;* Sw. *Haning.*

Honey was doubtless the first sweet substance known to the human race, for the bees had learned how to store up the nectar of the flowers long before man devised means of gathering the maple sap, or of expressing the sweet juices of the sugar cane or beetroot, and reducing them by evaporation. Commercial honey is the well-known thick nectar or vegetable juice extracted from flowers, and consists principally of a mixture of two sugars, dextrose and lævulose, in slightly varying, but nearly equal proportions.

It is produced by plants, not by bees; these useful little insects only gather and store it. Ordinary commercial honey is collected and stored by only one particular species of bee, *Apis mellifica*, although several other insects produce syrups nearly similar. Honey belongs to the carbonaceous foods, that is, to the same group as sugars, starches, hydrogen, and oxygen, with a trifling amount of colouring matter, flavouring substance, and water; but the bulk of all honey is sugar. It differs materially in flavour and quality according to the flowers from which it is drawn, the state of the weather when made, and the age of the bees.

Recent statistics show that the production of honey in Europe is about 80,000 tons annually and in the United States 30,000. England, although often compared to a "*hive*"—so busy are most of those who live in it—does not gather half the honey she requires, but imports about 1,000 tons a year, chiefly from Chili, Peru, St. Domingo, Cuba, and California, but honey also comes from Australia, West Indies, Canada, France, Italy, and Germany.

The best is the *Virgin Comb Honey*, which flows spontaneously from the comb taken from a young hive which has not swarmed, its white cells being whiter and better than that of succeeding years, when the cells have grown brown or even black. *Clover Honey* is usually a clear liquid, of greenish white colour, and may be run out of the comb without destroying it. *Heather Honey* has a rich amber shade and is somewhat viscid. Very sweet flowers give honey a pleasant smell and taste; while others of a poisonous nature, such as the *azalea*, *rhododendron*, etc., impart their properties to the honey, which, while not injurious to the bees are very dangerous to human beings. The hemlock of the Levant, for instance (*Cocculus suberosus*), renders the honey of Asia Minor very sweet but dangerously poisonous. Trebizond honeys in Asia are

frequently of this nature. The elm, broom, euphorbium, arbutus, and box yield bad honey. Bees often fill their cells with molasses, the juices of fruits, and the honey dew or sticky liquid off the leaves of the lime and other trees, and the honey is then very inferior. As a rule, Mountain honey is the best and whitest. Bees are supposed to suck a million flowers to make a pound of honey, and they require 11lbs. of honey to enable them to secrete 1lb. of wax. An abundant supply of wild thyme is said to be essential in the production of the best honey. Honey is composed chiefly of uncrystallisable or grape sugar, wax, gum, pollen, manna, and other vegetable or odoriferous substances and juices; but as it acquires more age the crystallisable sugar augments, a tendency which is increased by exposure to light and air. The most popular sorts are the Minorca, the Narbonne, the Gâtinais, the Chamounix, the Cretian, and the English, while large quantities are imported from Chili and the large bee farms of California.

Statistics show that Germany has 1,910,000 hives, producing 45,000,000lbs. of honey every year; Spain has 1,690,000 hives, producing 42,000,000lbs. of honey; in Austria there are 1,555,000 hives, producing 40,000,000lbs. of honey; in France, 950,000 hives, producing 22,000,000lbs.; in Holland, 240,000 hives, producing 6,000,000lbs.; in Russia, 110,000 hives, producing 2,000,000lbs.; in Denmark, 90,000 hives, producing the same; in Belgium, 200,000 hives, producing 5,000,000lbs.; in Greece, 30,000 hives, producing 3,000,000lbs. The annual production of honey in Europe is calculated to reach 80,000 tons, valued at £4,200,000, and of wax, 15,000 tons of the value of £1,350,000. A hive of bees produces from 20 to 50lbs. of honey yearly, according to the size of the hive, and multiplies ten-fold in five years. M. Bertrand, the famous French bee-keeper, has large hives containing 26 frames in each. In order to obtain enough honey for a load, a bee requires to visit 6,000 different flowers, and makes on an average 20 trips daily.

The United States crop exceeds 60,000,000lbs. from 2,800,000 hives. The largest bee-keeper is Mr. Harbicon, in California, who has 6,000 hives yielding about 200,000lbs. annually; but one of the largest beehives in the world is probably that at Beer Rock, California. The rock is, in fact, itself the hive. It is a granite boulder, rising abruptly from the bed of a little affluent of the Arroyo Alcade, and it is seamed and scored with fissures of divers sizes, whose depths have never been sounded. They are all inhabited by a vast population of bees, and overflow with honey. It is impossible to estimate the quantity stored in the hidden recesses, and it is needless to say that nobody would be bold enough to explore them. It is not without considerable peril that honey hunters rifle the bees of that which appears at the edge of and outside the fissures, and that comes to many hundred pounds' weight every year; but perhaps the biggest bee hive in the world is a natural one in Kentucky, known as the "Mammoth Bee-hive." It is in reality a huge cave, the main compartment of which is 150 feet high, the floor covering 10 acres in extent. The hive also is of solid rock, the roof having been entirely honeycombed by bees.

Honey always takes its flavour from the flowers. Crete, Minorca, and Narbonne honeys derive their flavour from rosemary; that from Provence from lavender, and that from Naples, Valence, and Cuba from orange flowers.

Honey obtained from heath blossom is generally yellow, bitter, and syrupy. Corsican, being gathered chiefly from box-tree flowers, is also very bitter, and so is Sardinian honey. The latter is used largely in absinth manufacture.

In Brittany the honey got from buck wheat is generally very brown, and leaves a very disagreeable after-taste. The bees of Bourbon, or Réunion produce greenish honey, which retains the perfume of the flowers of the *Acacia heterophylla*.

The mountain honey of Chamounix, of greyish colour, is extracted from various Alpine plants, and justly celebrated for its exquisite flavour.

The bees of Mount Hybla, in Sicily, have only thyme to feed on. The white liquid honey of Mount Hymetta, in Greece, owes its exquisite flavour and transparency to the *Labiatæ*, which cover that mountain; that of Southern India to the *Strobilanthus*.

As already shown, Virgin Honey is the best; the second in quality is *White Honey*, got out of the combs first by slightly cutting or bruising the cells, and hanging them up, when the honey drips out and is drained through a coarse cloth, and soon assumes a thick, white, and almost solid substance. Subsequent pressure draws forth a third quality, and a fourth of darker colour is obtained by slightly warming the combs. Honey in a clear state sells best, and that which becomes crystallised and thick by long keeping should be warmed very slowly to about 80 to 90 degrees, but not higher, or the flavour will suffer. It is often rudely spoiled by being melted down rapidly and strained. It would clarify itself if stored in a warmer place and left alone a few days or weeks.

If wanted to "set" put it in a cooler place. If wanted to be kept in a liquid state, which is far the best, keep it in a warm, dry place.

As a food honey eaten in moderation is said to be nutritive and mildly laxative. It is used by tobacco manufacturers to add sweetness, flavour, and perhaps weight to certain kinds, and in medicine it is an important demulcent, a flavouring agent in syrups, gargles, pill-masses, and mixtures. Honey, both strained and comb, is commonly adulterated with starch syrup. This syrup is first made from potato starch and oil of vitriol. It is then mixed with a little genuine honey, but it lacks sweetness, and taste is the readiest test. It is often adulterated with glucose, sugar, syrups, treacle, and with starch flour; the latter may be discovered by mixing in a little warm water, which dissolves the honey but not the flour. Artificial honey has recently become an important by-product of the German beet-root sugar distilleries.

Imitation honey is often wholly made from corn-syrup or starch-sugar, a cheap, crude material obtained from potatoes and sulphuric acid, or from maize, or even from rags, and sulphuric acid. More frequently it is made of glucose and dextrine. A simple method of testing what is pure and what is artificial honey is to add a little pure alcohol to it, dissolved in an equal volume of water. This solution, on being shaken up with alcohol, remains nearly clear in the case of honey, but in the case of the imitation it at once becomes opaque like dirty milk, due to the deposition of dextrine from the starch-sugar.

A patent for making a Honey substitute from beet sugar glucose and water was actually taken out by Mr. Charles Lyle and his chemist, Mr. Eastick, in 1885, but such a product has really no right to the name of honey.

English honey is chiefly collected from furze and broom flowers, and is more waxy than that from the South of Europe. American or Californian and Swiss honeys are mostly adulterated with corn or starch syrup.

Clarified Honey, also called *Refined Honey* or *Strained Honey*, is less agreeable to the taste than raw honey, but it is less liable to ferment. How to clarify:—Mix 1 cwt. honey with 9 gallons water, add 7lbs. animal charcoal; simmer for 15 minutes (add a little chalk to saturate any free acid), strain well, and finally evaporate to consistency desired.

Honey when too dark in colour may also be decolourised by gently warming it with granular animal charcoal and filtering while hot through a layer of the same substance in a cylindrical percolator.

Vague titles, like *Swiss Honey*, *Honey-dew*, *Refined Honey*, *Table Honey* (*prepared for table use*), or *Finest Prepared Table Honey* are often applied to adulterated preparations. *Clarified Honey* is prepared by melting in a water bath and removing the scum and straining it while hot through flannel, and this is the kind generally used medicinally. *Sugar Honey* is an imitation of or a

substitute for natural honey. It is a kind of *syrup* composed of water and inverted sugar, a little mineral substance, and a little free acid. It has the taste and smell of the natural product, and, as far as known, is without any element not contained in genuine bees' honey.

Another imitation, known as sugar honey can be easily obtained by the two following operations:—(*a*) Inversion of normal sugar by *pure* sulphuric acid, which is most easy. Normal sugar is dissolved in five to six times its weight of water, previously made acid to $\frac{1}{2000}$ or $\frac{1}{1000}$ by sulphuric acid; the solution is boiled during five minutes and the inversion is produced. The sulphuric acid is eliminated by means of pure carbonate of baryta, of which a very slight excess is beneficial. It is filtered and evaporated either in the air, or, better still, in a vacuum. If the evaporation is made in the air an invert sugar is obtained exactly similar to that of the best natural honeys, but more or less brownish yellow in colour. But in a vacuum a colourless honey is obtained, or almost colourless, according to the quality of normal sugar employed. Refined sugars or candies give such, the refined at least as well as colourless candies.

Sugar honey thus prepared differs in nowise from the natural sugar gathered by the bees; but it differs from honey in this, that it has not got the special odour of the flowers; the chemist has not got the wings of bees, and does not go like them to gather the sugar and scent. He is compelled to *borrow* this perfume from them, of which he may manage to make an exact imitation, but not without great expense and methods not perhaps quite free from danger.

If 2lbs. of natural bees' honey be added to every 100lbs. of the above, a very fair article is undoubtedly produced.

For *Honey-Water*, see *Mead*.

The extreme suitability of climate and flora for bee-farming purposes in New South Wales is leading to a steady annual increase of honey production in that colony, with the result that efforts are being persistently made, and not unsuccessfully, to include honey among the more important articles of Australian export. The bee farms are to be found in many portions of the colony, several of the largest being in the Blue Mountain and Western districts. Among these latter is one near Orange, which affords an interesting example of the manner in which the Australian bee-farming industry is conducted. The country for some distance back from the farm is still a forest, in which a large portion of the trees are red gum, the others being principally box trees. The red gums are the main dependence of the bee-keeper, though the box gives a fair supply of honey. Recently increased attention has been given to the best methods of honey production, the bee farmers in New South Wales being sufficiently numerous to support a monthly paper, the *Australian Bee Bulletin*, and to hold occasional conferences for the purpose of discussing matters affecting the bee-farming industry. The experimental shipments of Australian honey to London have been watched with much interest. Some recently sent from Sydney arrived in excellent condition, not having suffered from the intense heat of the Red Sea. Should Australian honey find a good place in the British market, there is practically no limit to its production, the colony being capable of producing many millions of pounds annually.

Brazilian Honey is chiefly employed in medicines. In some districts of the River Plate, a kind of honey made by a very small bee is called *Alpamisqua*.

For *Ethiopian Honey*, see *Tazma*.

Honey is largely used in pharmacy, also in making gingerbread, as well as certain sweets and fermented liquors. It should be chosen light-coloured and new. If kept too long it crystallises and loses flavour, although "candying" is one of the best proofs of its purity.

Comb honey and how to handle it.—You must not drop it. Hold it only by the wood, and when removing it from the crate, or at any other time, do not break the delicate cappings covering the cell, otherwise the honey will run out. Where to keep it—in a warm, dry room, say, 80° or 90° F. No place too warm in

which a person can live. Never put it in a cellar, as honey will draw dampness and cause the cappings to break and the honey to leak and turn rancid. "Honey in the comb" has sometimes been artificially made—the comb from paraffin wax and the imitation cells filled with glucose.

Special Firms.—Kimpton Brothers, 36 and 37 Mincing Lane, London, E.C.; John Parkes & Co., Priory Works, Warwick; Geo. Rose (Finest English Honey), 50 Great Charlotte Street, Liverpool, and branches; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Honey Dew Tobacco.—The commercial name for a kind of chewing tobacco which has been moistened and prepared with molasses.

Honey Soap rarely has any honey in it, although strictly it should contain about 1 oz. of honey in each pound of soap. It is mostly made 3 parts of curd soap, 1 part palm oil soap, and 1 part olive oil soap, melted together and scented with oil of citronella, verbena, ginger-grass, or rosemary.

Some makes consist of 7lbs. finest yellow soap melted with ¼lb. olive oil and similarly perfumed. Many of the so-called Honey Soaps owe their texture to extensive pearl-ashing, and consequently contain an injurious amount of free alkali.

Honig Tea consists of the dried stalks and leaves of the shrub *Cyclopia genistoides*. It has a pleasant aroma and an agreeable astringent flavour. Used in Africa.

Hoola Kins.—See *Eulachon Fish* and *Oil*.

Hop Ale.—Hop Ale is made in a similar manner to ginger-beer. Dissolve 8lbs. of moist sugar in 8 gallons of water, to this add a mixture of tr. lupuli zij. and tr. chiratæ ziss., with 20 drops of essence of pineapple. Float a slice of toast upon the liquor, and pour upon it 4 ozs. of fresh yeast. Ferment at a temperature of 70° to 80° F. for a day, strain and bottle. The colour may be brought up with caramel, or a part of the sugar may be replaced by treacle.

Most Hop Ales are really fermented light ales, and are non-alcoholic in the Excise sense only, that is, they contain about 2 per cent. of proof spirit. Fermentation of the mash appears to be stopped at a certain point, then the clear ale is slightly carbonated, and salicylic acid or other preservative added. (See *Non-alcoholic Beers*.)

Hop Bitters.—Intended to be used as a tonic.

(1) Soak an ounce of hops in a pint of boiling water, leave them two hours, then strain. Dose: About a wine-glass of this filled up with water. For bottling to keep, add a small quantity of spirits. These bitters are sedative, but not narcotic, and are perfectly harmless, also considered more valuable than gentian, chamomiles, etc.

(2) Concentrated solution of chamomile, 3 ozs.; concentrated infusion of buchu, 2 ozs.; concentrated infusion of hops, 8 ozs.; concentrated infusion of gentian, 3 ozs.; glycerin, 3 ozs.; mix with water recently boiled and cooled, so as to make up to 48 fluid ozs.

Hopkos.—See *Temperance Drinks*.

Hops.—Da. and Sw. *Humle;* Du. *Hoppen;* F. *Houblon;* G. *Hopfen;* It. *Lupolo;* Port. and Sp. *Lupulo;* W. *Pensag*.

The ripened catkins, flowers, or seed cones of the hop-plant, of which there is only one species, *Humulus lupulus*, a perennial climbing vine, growing luxuriously three or four together up hop poles some 12 or 20 feet high, and yielding the bitter principle, known as *Lupulin*. Hops first came to England from Artois about 1524; but were in use 2000 B.C. in the dual capacity of an intoxicating beverage and as a medicine. This is attested by pictures of the plant on Egyptian monuments of that date. Although increasing in consumption, the area of hop cultivation in this country has latterly been declining. The annual consumption is at least 650,000 cwts., while the home crop yields little more than half that quantity, the remainder

being imported from the Continent and America. The present acreage in England is only about 58,000, viz., 35,000 in Kent, 7,000 in Sussex, 6,000 in Hereford, and 2,000 to 3,000 each in Worcester, Hants, and Surrey. The Kentish crop of course "makes the year," but the cultivation in that county has fallen off, while in Hampshire, Hereford, Shropshire, Worcester, and also in Sussex it has been increasing these last few years. The best varieties are known as *Hill Golding*, *East Kent Golding*, *Golden Hops*, *Jones's Hops*, *Grape Hops*, and *Farnham White Bine*.

HOPS.

The Goldings are very fine and rich. Jones's are of shorter growth and do not require such long poles. The *Colegates* and *Grape Hops* are hardy and prolific on even poor soils.

The best *White Bines* are grown at Farnham, in Surrey, and the next at Canterbury, in Kent, and yield 2 cwts. to 20 cwts per acre. The hops are ripe when the flowers turn a brown amber colour, and the plant is then severed near the root and removed with the pole, which is laid down on wooden frames, and the cones are then picked off by women and children. The lighter coloured and finest of these are picked, dried in a kiln, and packed in pockets of 1½ cwt. each for ale brewers; the darker and inferior qualities in bags of about double the weight of pockets for porter brewers. Mid-Kent and Sussex hops have an inferior colour and flavour. *Red Hops* used to be considered very fine and aromatic, but the *white* varieties are now more in favour both for flavour and general brewing qualities.

A variety known as the "Meopham" has during the last few years been somewhat largely cultivated in the Weald of Kent and Sussex, but although a hardy heavy cropper and early ripener, it is only poor in quality. The roughest bined hop of all is the *Colegate*, which can easily be distinguished by this, both in the hop garden and when cured and bagged.

The best hops may be known by the tight packing and perfect dryness of the unbroken cones, and the clammy feeling of the powder contained in them; also by their flavour, scent, thickness, and bright colour. As a rule they are also small and compact in the cone, while the coarser sorts are larger and loosely set on the string. The great hop market in England is the Hop Exchange, Southwark Street, London. The prices of hops depend both on the yield, whether 2 or 20 cwts. to the acre, and on the season, whether wet or dry, also on the extent of the ravages of the aphis blight, drought, red spider, and mould. They fluctuate from £2 to £20 per cwt.

If properly preserved the produce of a good season may be profitably held over for years of scarcity. When hops are older than of last season's growth they are termed "yearlings," when of second season's growth, "old," and when three years or older, "old odds."

There are no authentic documents to prove where hops were first grown, but eminent botanists like Linnæus and De Candolle entertain the opinion that the plant originated in Eastern Russia. Etymologists also affirm that all European languages have derived their designation for hops from the Slavic word

"*Chmel*," which means *hops*, and there exists evidence to prove that the Slavs were the first to add hops to their beer. As above stated they reached England from Germany about 1524, and are used for imparting to beers an aromatic bitterness, brightness, and clearness, and to prevent souring. (See *Ales*.)

They soon lose much of their strength and fine flavour if not kept properly, and no brewer who knows his business will buy slack dried or cold bagged hops, except for immediate use.

It has been ascertained that hops contain two kinds of resin which have certain preservative powers. The harder one is better than the soft or *oleo* resin, and Bavarian growths possess twice as much of this preservative power as the English, although the latter are far superior in flavour. Germany exports to this country large quantities of Bohemian and Bavarian hops, but some of them are occasionally found to be repacks of Russian growth. About 30,000 cwts of Russian hops come yearly to England, but most of them are much inferior to Bavarian. There is, however, one kind of Russian raised from the best Bohemian (Saaz) and Bavarian (Spalter) sets of plants, which is equal to the best known brands in the market, and at the same time very much cheaper. Bohemia cultivates some 26,000 acres—chiefly red hops—which yield about 9,000,000lbs. yearly, and the kind with greenish-yellow flowers, grown in the Saaz or Saaltz district, and known as *Stadt*, or City hops, are considered the best in the world. The flowers are long, closed at top, and contain 100 to 150 leaflets, very soft and velvety to the touch. When ripe they assume a red tint, but possess a very spicy aroma, and are very bitter. *Auscha* is another hop producing district in Bohemia; quality somewhat inferior, but large quantities are sent to England and to Scandinavia. *Bezirks* and *Kreis* are lower grades, especially the latter. *Daubo* hops are a green variety with round flowers of only 40 to 60 leaflets. *Raconitz* produces fine hops, almost equal to the Saaltz. In Persia hops grow wild in the jungle and thickets lining the main roads about Resht, but no use is even now made of them, and they are not collected. Alsace also produces hops. In the United States, California is the chief producing State.

In addition to their primary use in brewing, hops are sometimes used for making pillows to cure neuralgia and to induce sleep, but should first be carefully broken up by hand, and thoroughly dried before the fire. They are also occasionally employed in making poultices and hot fomentations for gout, rheumatic affections, bruises, etc., and considered an excellent remedy.

A new use is reported to have been discovered for hops—namely, the curing of bacon. It is found that a sprinkling of hops in the brine when bacon and hams are put in pickle adds greatly to the flavour of both, and enables them to be kept an indefinite period.

Horehound (sometimes spelt *Hoarhound*).—A small cottony herbaceous plant, *Marrubium vulgare*, largely grown in California, frequently cultivated, or perhaps tolerated, in English gardens, but more often growing wild on waysides, waste ground, old walls, etc.

HOREHOUND.

It usually grows 12 to 18 inches high, has several small branches and bushy

wrinkled leaves, while the flowers are white and crowded at the axils of the leaves, the whole being covered with a white cottony down. This herb, like many others, used to have in old times a host of virtues which might turn the patent medicine vendor of to-day green with envy!

Horehound has an aromatic, but not very pleasant smell, and is much used to flavour honey, as a reemdy for coughs and colds, as also is *Syrup of Horehound*, a mixture of horehound juice and sugar.

Hors d'Œuvres.—A French term used in bills of fare by caterers for small *side dishes*, or savoury "whets" for the appetite. In Russia called "*Zakuska.*"

Horse Chestnuts.—(See also *Chestnuts.*)—The nuts or fruit of the highly ornamental horse-chestnut tree, *Æsculus hippocastanum.* Removed from their three-lobed prickly capsule the seeds—one or two in number—resemble the ordinary edible chestnut, and although very coarse and bitter, a flour called *Polenta* is made from it on the Continent. The tree has a magnificent foliage and blossom. The bark is used as a febrifuge, but the timber is of little value.

The vessels of the leaf-stalk are arranged in the shape of a horse. The nuts are also supposed to be beneficial in some diseases of the horse.

Large and coarse things have often the prefix "horse" attached them.

Horse Flesh as Human Food.—The consumption of horse flesh is, perhaps, greatest in Germany, but it is also very common in France. In 1892, in Berlin, 8,182 horses were slaughtered for the butchers' shops; in Breslau, 3,431; in Hamburg, 1,727; Dresden, 1,428; Cologne, 1,415; Hanover, 1,400; Madgeburg, 1,193; Leipzig, 1,053; and in some of the smaller towns the proportions are greater. The greater part of it is consumed by the poorer classes, and in the "People's kitchens," which aim at supplying substantial soups, sausages, bouilli, etc., at lowest prices.

Horseflesh also appears to hold its own as an article of food with the poorer classes in France and Belgium. Recent statistics showed that in Antwerp alone nearly 4,000 horses were slaughtered in 1896 for human consumption, and the number of shops dealing exclusively in horseflesh in the Belgian port exceeds thirty. Over 10,000 horses were imported into that country during the year for conversion into meat, this number being largely in excess of the imports of cattle. Ghent alone received about 5,000 used-up animals from London.

This inexpensive article of diet is by no means despised by the labouring classes in that country. English-speaking people, on the contrary, nowhere exhibit any tendency to hippophagy.

Horse Mackerel.—See *Tunny Fish.*

Horse-radish.—Da. *Peberrod;* Du. *Rammenas;* F. *Rave, Raifort;* G. *Meer-rettig;* It. *Rafano;* Port. *Rabao;* R. *Khrèn;* Sp. *Rábano picante;* Sw. *Pepparrot;* W. *Rhuddygl y meirch.*

The pungent and stimulating root of the perennial herbaceous plant *Cochlearia armoracia*, a species of scurvy-grass.

It is mentioned in the Egyptian records as a medicine and condiment 2,000 years B.C. This root contains a volatile oil very similar to mustard oil, with about 30 per cent. of sulphur, and is one of the most effective anti-scorbutics known. Horse-radish provokes the appetite, and aids digestion; it is usually scraped raw and used as an accompaniment to roast beef, both as a condiment and garnish, the taste of it being warm and pungent like mustard. Considerable quantities of horse-radish are imported from Holland and Germany in large casks. The root is at its prime at one year's growth, but the Dutch, although very cheap, are often three years old, being grown from "jags" or "snags" (small thin rootlets), and, although large and plump, are tough and almost tasteless. They may be known by the forked

rootlets at the bottom of the stick and their dirty sandy colour, and they often show a little leaf, grown and bleached in the barrel.

The English growths are small and rugged, but far the best in pungency and flavour, and are cut straight off with the spade, also without roots at the end of the stick, but a small green tuft just beginning to grow on the crown.

The poisonous roots of Monkshood, or Wolfsbane (aconite root), are occasionally mistaken for horse-radish. These poisonous roots are short—only 1 to 3 inches long—and tapering to a point, seldom being thicker at the crown than a person's finger; they are also covered with a blackish or nut-brown skin, have a bitter, earthy taste, and disagreeable odour, producing on the tongue, if a minute portion be cautiously chewed, a prolonged tingling and a sensation of numbness; while the edible horse-radish roots have longer lengths, say 7 to 10 inches, and are of more even thickness from end to end; the skin also is cream coloured or yellowy-white. There are very few branches to the root, and it is marked with a few transverse scars. When bruised and wetted it gives off a pungent odour. Horse-radish is in season from October to June, but may be kept fresh a long time in sand and in a cool place.

Horse-radish Powder is usually prepared by taking up the roots in November or December, carefully drying with a gentle heat. After being reduced to powder it is corked in bottles, say 6 oz. size, to retail at 9d. to 1/- each.

Horseradish, as above observed, is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion; but it is also occasionally employed in medicine, particularly in dropsy attended with enfeebled digestion and general debility. It has, moreover, been recommnded in palsy and chronic rheumatism, both as an internal and an external remedy, and in scorbutic affections is highly esteemed.

A great number of horse-radish condiments have been put on the market from time to time, but *Bayle's Horse-radish Mustard*," prepared at St. Louis, is a general favourite throughout the United States, and is bound to become more widely known year after year, for, although not often seen in England, where there are older preparations, it is unquestionably superior to any in purity and dietetic excellence.

Horse-radish Sauce.—F. *Sauce Raifort à la Crême;* G. *Meerrettisch-Sauce.*

This is very cheaply made. Mix about four tablespoonfuls of finely-grated horse-radish with a teaspoonful of white sugar, 1 oz. of salt, half a teaspoonful of ground white pepper, and two teaspoonfuls of ground mustard. Then add sufficient vinegar to bring to the consistency of cream. Bottle, and cork well. It often consists of grated horse-radish and strong vinegar only. (See also *Sauces.*)

Horse-radish sauce is served with either hot roast beef or mutton, also made by scraping about 2 ozs. of horse-radish. Stir it into half a pint of cream made boiling hot, add 1 oz. of fine white bread crumbs, a little milk, a pinch of cayenne pepper, same of salt, and just before taking to table stir in the juice of half a fresh lemon.

Horse-radish Tree.—A common name for the *Moringa pterygosperma*, a tree common in many parts of India, and cultivated in several other tropical countries. The fruit may be eaten fresh as a vegetable or pickled. Its seeds furnish the *Oil of Ben*, used by watchmakers. The bark supplies a gum like *tragacanth*, and the leaves are used in *curries* and as sinapisms; and although the horse-radish tree is no relation to the familiar English horse-radish plant, yet its fresh roots

have a pungent odour and a warm taste.

Horse-radish Vinegar.—Pour a quart of best vinegar on 3 ozs. of scraped horse-radish, 1 oz. of minced shalot, and 1 drm. of cayenne; let it stand a week, and you will have an excellent relish for cold beef, salads, etc., costing scarcely anything. Horse-radish is in the highest perfection about November. (See also *Vinegar*.)

Hosika.—A name in Japan for dried sardines, which are used extensively for manure.

Hot Cross Buns.—See page 151.

Hotch-potch or **Hodge-Podge.**—This famous Scottish dish, formerly called "*Salmagundi*," is a kind of mutton broth or vegetarian soup, and usually consists of green peas (not pearl barley), cabbage, carrots, turnips, onions, parsley, and other herbs, all chopped or grated fine, and then boiled in water, with neck or back ribs of mutton, for about two hours; a little butter, salt, and pepper are added; and lettuce, celery, white cabbage sliced, asparagus points, etc., are often used. Sometimes the mutton is cut up in pieces and sometimes left in a lump to be sliced up at table as the soup is served. Some boil the empty hulls, swads, or shells of the peas in a little water, and add the strained liquor to the rest. Hotch-potch is considered the *chef d'œuvre* of Scotch cookery.

Hottentots' Tea.—This consists of the leaves of one or more species of Helichrysum, a large genus of composite plants cultivated in South Africa. The flowers are yellow, and commonly known as everlasting, or immortelles. The beverage has a very agreeable aroma, and is highly appreciated by the natives.

Hovis Bread.—The special peculiarity of this patent brown bread seems to be that the flour from which it is prepared is mixed wih the ground germ or embryo of the wheat grain. In making the bread, kneading or moulding must be avoided, and it must be baked rather longer than ordinary bread.

Huckleberries.—A general name in the United States for several species of heather berries. (See *Whortleberries*.)

Hugon's "Atora" Refined Beef Suet.—Made from fresh English beef suet only, by Hugon's process. Absolutely pure; saves trouble of chopping; used for puddings, pie-crust, cakes, frying, and cooking generally. Remains sweet an indefinite time; and being free from skin, tissues, and moisture, goes twice as far as raw suet.

Huile d'Enfer, Huile de Nice, Huile de Provence.—See *Olive Oil*.

Hulled Corn.—A preparation of whole grains of Indian corn, or maize, for food; made by maceration in a weak lye, to remove the hulls, or husks, and subsequently cleansing and thoroughly boiling in milk.

Humanised Milk.—(See also *Milk*, *Condensed Milk*, *Cream*, etc.)—To render cows' milk more like human milk for infants' use we have humanised condensed milks. In these preparations human milk is imitated by condensing cows' milk to one-third its bulk, and adding cream and a saturated solution of milk-sugar to bring the mixture to the required composition. For children some of the highest authorities say that the best substitute for mothers' milk is cows' milk, diluted with one-fifth of its weight of hot water, and with a little sugar and salt added. It is very essential for infants that their food should always be fresh.

Hungarian Wines.—The most commonly met with are:—Oedenburger, Samlauer, Neszmely, Carlowitz, and Erlauer. Carlowitz is the best known.

The *White Wines* comprise Miszla, Balaton, Füred, Hont, Pesth, Weissenburger; and the *Red Wines* Baranya, Presburger, Somogy, Vagh-Ujhelyer, Paulitsch, and Erdröd.

Gratz, in Styria, also produces champagnes, burgundies, hocks, and clarets.

Maszlac is of four different kinds. Meograd, Krasso, and Villany, produced in the West of Hungary, are good strong wines of the second class. The varieties known as Ausbrach and Maszlacs, as well as the Tokays, Rust Menes, etc., are considered the best. There is also a large number of inferior qualities.

Hung Beef.—(See p. 95, also *Corned Beef, Tasajo.*) — This is preserved by salting, and drying either with or without smoke. It is first hung three or four days till tender, then salted with brine, bay salt, brown sugar, saltpetre, and a little pepper and allspice. It is afterwards rolled tight in a cloth and hung in a warm dry place for two or three weeks till hard. If smoked at this stage it will keep a long time.

Scotch Beef-Ham is the flesh of bovine animals, and now generally limited to that of the ox, cow, or bullock. Before the days of fresh-meat markets and railways it was customary for families, especially in the country, to lay in stocks of salt beef in October or November to last till the following summer. Glasgow has long been famous for its boiled beef-hams, and considerable quantities are still prepared in Scotland, and sent ready cooked to retail provision dealers in most large towns. Cork also exports salt beef to the East and West Indies.

Hunyadi Janos. — A registered brand of natural mineral water produced in Hungary, from wells sunk by Mr. Andreas Saxlehner in 1864 at some springs near Buda Pesth. It is named after a Hungarian hero who flourished in the 13th century. It is very bitter, and possesses valuable aperient properties, and on analysis appears to be composed of:—

Calcic sulphate ...	0·41
Magnesic do.	16·05
Sodic do.	25·00
Magnesic chloride ...	1·20
Silica	0·12
Water	957·22
	1,000·00

Although some medical authorities, and of course the proprietors of the wells, are of opinion that natural waters cannot be reproduced by artificial means, yet if the salts and gases composing these spa waters be correctly known, there ought not to be much difficulty in our mineral water manufacturers producing them at home, and so rendering it unnecessary either to visit the distant spas or import these foreign waters. In fact, it is said that more of these bottled waters are really manufactured in this country than are imported.

Hurreah. — A spirit used at Chyebana, in the district of Barrackpore.

Hurtleberries or Hurts. — See *Whortleberries.*

Hydroleine, which has been much advertised in American and English papers, and claimed to be very strengthening, contains (according to the statements of the manufacturer) in two teaspoonfuls (120 drops) 30 drops of purest cod-liver oil, 35 drops of distilled water, 6 grains of soluble pancreatine, ⅓ grain of soda, ¼ grain of boracic acid, and 1·20 gr. of glycocholic acid.

Hydromel.— See *Mead.*

Hyson Tea. — (See also *Chinese Teas.*)—*Hyson,* or *Hichun* (literally meaning "blooming spring" or "fair spring"), is a name for certain kinds of green teas of the first crop, and were until lately highly esteemed in this country. The leaves are large and rolled up lengthways, heavy and very brittle, and of a silvery green colour. The infusion is limpid, amber-coloured, and, like all green teas, rather tart. It yields 48 to 50 per cent. of soluble matter; but owing to the artificial and injurious colouring matter with which the Chinese adulterated them, all green teas have gone much out of favour. They are packed in half-chests and boxes, averaging 58lbs. and 17lbs. each.

Young Hyson, or *Hyson Junior*—from Chinese *Yu Tsien* ("before the rains") or *Tu Chun* ("flourishing spring")—means hyson tea picked early, before the rains, while the leaves are small and delicate. This tea contains about 52 per cent. of soluble

matter, and is considered superior to ordinary hyson. Half-chests hold about 65lbs., and boxes 25lbs.

Hyson Skin, the badly rolled, small, or refuse hyson, with discoloured or yellow leaves. It yields only about 43 per cent. of soluble matter, the coarser or rougher being termed *tea-bones*.

Cowslip Hyson is a flavoured sort, made by mixing with it the berries of *Chloranthus*, or by alternate layers of tea and dried and sifted cowslip flowers.

I

Ice.—Da. *Iis;* Du. *Ijs;* F. *Glace;* G. *Eis;* It. *Ghiaccio;* Per. *Yach;* Port. *Gelo, Caramelo;* R. *Leodt;* Sp. *Hielo;* W. *Rhew.*

Ice is now used very extensively for a variety of purposes. In some parts of America there is more money spent in ice than in fuel. Two or three hundred thousand tons a year often come from Norway, and a vast quantity from Boston and other American ports. Its chief value consists in its antiseptic property, and its principal uses are the preservation of articles of food, cooling of liquors, etc., and for medical and other purposes. Large quantities are also regularly used in the larger bacon factories.

Meats and fish are preserved fresh by it more conveniently and efficiently than by any other means, and its largest consumption is in the great markets of our cities. Besides that used in shops, hotels, etc., most of the steam-ships leaving England take 6 or 10 tons aboard.

Vessels at sea need not now, as formerly, depend for fresh meat upon live animals taken on board at great inconvenience, but, by means of a small ice-house, they can preserve their supplies fresh for a considerable voyage and in all climates.

The handiest way of keeping ice for domestic use is by the refrigerator or portable ice-chest, which should be selected with care, for those badly made only assist in melting instead of preserving the ice. When the chest is properly made the temperature can be adjusted at pleasure, while the food, wines, water, and other articles placed in it are most enjoyable in hot, sultry seasons.

There is one precaution necessary to notice, that the use of ice, in any form, must not be pushed too far, so as to lower the temperature of the person unduly, or given when the temperature of the body is already low. Ice is well known to have a powerful effect in stopping inward bleeding, and the pulse in temporary derangements comes down very considerably under the free use of ice-cold milk.

A physician states that ice water does not quench thirst. The most efficient way to allay thirst is to thoroughly rinse the mouth with not more than a tablespoonful of water; this will quench the thirst as effectually as a quart of water hastily swallowed, and will not have any injurious effect. He adds that he believed fully one-third of the deaths during the heated season are, if the truth were known, directly or indirectly due to freely drinking of ice-water.

Iced Milk.—In acute inflammatory diseases, iced cold milk freely used is of the greatest advantage. A small piece of ice, about a square inch, put into a cup of milk, allowed to stand for a time, or stirred for a minute or two, will make a better drink for the patient than water, being nourishing, as well as quenching the thirst.

To break ice tap it with a sharp-pointed metal instrument, similar to a brad-awl but longer; the sharper the point the easier the ice is broken. It may be easily split with a strong needle better than with a hammer.

About 3lbs. of salt mixed with every dozen pounds of ice is very useful to generate a greater degree of cold.

Ice Cream.—F. *Glace à la Crème;* G. *Rahm-Eis;* Port. *Sorvete;* Sp. *Helado, Sorbet.*

Ice creams are made of various qualities, from cream, milk, and sweetened water. Sometimes instead

of cream the ingredients of a custard—egg, cornflour, etc.—are used. A fair quality is produced by whisking 4 eggs, ¼lb. sugar, and 1 oz. fresh butter in a quart of new milk; place the mixture in a pan on the fire and stir well till it nearly boils. Then empty it into "the freezer," adding a little essence (lemon, raspberry, strawberry, or vanilla), and "freeze" in the usual way in a freezing machine. (The handiest and most reliable freezers may be had from Parnall & Sons, Narrow Wine Street, Bristol, who are noted for their ice appliances.) As the mixture freezes, it should be worked down from the sides of the freezer with a wooden spoon or spatula, so as to make the mass of uniform consistence.

A good freezing mixture is also made by mixing one part by weight of powdered sal ammoniac with two parts of powdered nitre; common washing soda is next reduced to a powder, and both are then kept in well-corked bottles ready for use. When wanted, take an equal quantity of each, using sufficient water to dissolve them, and then freeze.

Another:—2 pints new milk, 6 eggs, ¼lb. white sugar; mix, strain, heat to near boiling point, and, when cooled, freeze. (See also *Neapolitan Cream.*)

The apparatus necessary for freezing are the pewter freezer, the ice pail, and wooden spatula.

In actual practice a mixture of 1lb. of rough salt to every 3lbs. of small ice will be found to give the best result.

Another good basis is: 3 pints of new milk, 1 tin best condensed milk, and yolks of 4 eggs.

Mix and heat gently with constant stirring to make a custard. Then cool and put into the freezer, which is packed round with ice and salt. Whirl the freezer round for 5 minutes. Then take off lid and scrape down the frozen ice off the sides. Again whirl and scrape, repeating the process until a uniform butter-like mass results.

The above basis can be flavoured with vanilla, orange, lemon, almond, or any other flavouring.

To make a specially rich ice, substitute raw cream sweetened with sugar for the quantity of milk given above.

Fruit Ices are made by using fruit jams with the above, adding the juice of a lemon to each pound of jam, and then pulping the whole through a sieve before mixing with the custard and freezing (say one part of pulp with two of custard). Tinned pine-apples, cut into small pieces and bruised in a mortar, are often used in this way.

The first mention of *ice cream* found in history is in the account of the festivities in New York following Washington's first inauguration as President of the United States, in 1789, when ice creams were prepared under the direct supervision of Dolly Adams, wife of John Adams, the second president.

Ice Creams.—Mr. John May, of 114 Church Street, Croydon, Surrey, supplies a Desiccated Ice Cream Powder, in various flavours, which simply require the addition of boiling milk, and is specially packed for the grocery and allied trades. Full particulars upon application, including Dr. Goodfellow's report upon the article. Freezing Machines and Wafer Biscuit Moulds also supplied.

Iceland Moss, or **Lichen Islandicus.** — F. *Lichen d'Islande:* G. *Islandische Flechte.*

This is not really a moss, but a true lichen, distinguished as *Cetraria islandica,* which grows two to four feet high on several Icelandic mountain tracks which are otherwise desert. It is largely used in that country for feeding cattle, pigs, etc., and has long been used in England either alone or in conjunction with other ingredients as human food. It is said to be native of Britain, and large quantities are collected on the barren hills of Sweden, which is, indeed, the only country now exporting the article. It is much darker in colour than Irish moss and presents a more drooping and shrivelled appearance, but is quite soluble in hot water, and forms a jelly when cold.

Its natural bitterness is removed by soaking for about 15 minutes each time in several hot waters and finally boiling, or it may also be removed by digesting, say, 1lb. of it in 1½ gals. of cold water, containing 1 oz. pearlash, then draining

the lichen, edulcorating with cold water, and boiling it in a gallon of water till one-third of the liquid be evaporated. The resulting jelly if very dark may be dried, dissolved, and done over again.

It contains about 30 per cent. of lichen starch, but not a particle of gelatine. It is often boiled with milk and made into a very agreeable jelly-like food for invalids, etc. If made with water only, half its weight of liquorice-root added to the dry moss makes a great improvement.

In some Northern countries it is often pounded into bread.

Icing for Cakes, Biscuits, etc.—This should be made of white sugar and albumen. Beat the white of eggs to a full froth with a little rose or orange flower water, then add gradually as much finely powdered sugar as will make it thick enough, beating it well all the time. In applying it the cakes are first dusted over with flour, gently rubbed, and then the icing is applied either with a flat knife or with an icing tube. The ornaments are stuck on and all embellishments made while it is wet, and then the cake is set in the oven for a few minutes to harden, but not long enough to discolour the icing. Piping a bride's-cake is one of the most artistic operations of the expert confectioner, instructions for doing which cannot be satisfactorily conveyed in words. It requires a good deal of practice.

Icing Sugar. — See *Confectioners' Icing* and *Caster Sugars.*

Imitation Cheese.—See *Margarine-cheese.*

Immortelles, or Everlasting Flowers.—See *Flowers* and *Nosegays.*

Imperial Tea. —F. *Gros perlé.* (See also *Green Teas.*)

This does not constitute any particular species, but is a name given to any superior selection from the best green teas, such as Hyson, Gunpowder, Twankay, etc., and consists of the larger leaves of these varieties. In China "Imperial" tea means the choice tea used only by the Emperor and other self-styled "sons of heaven."

Imphec, or African Sugar Cane.—An African species of the common sorghum, and identified as *Sorghum caffrorum.* It is cultivated by the Zulus, both for sugar and for its starchy seeds. (See *Sorghum.*)

Incense. — F. *Encens.* (See also *Frankincense, Thus,* etc.)

A mixture of fragrant gums and spices which exhales perfume when set on fire. There does not appear to be any regular formula, every maker having his own favourite recipe.

Generally, it contains gum *olibanum* (which see), benzoin, styrax, and powdered cascarilla bark well mingled together. In use the powder is so placed that as the censer is swung round it drops little by little on to a hot plate, and the smoke escapes through little holes in the censer.

In ancient times the use of incense was general at all places of worship. It was burnt by most of the oriental natives in honour of their divinities. The Hebrews possessed in their temples the altar of perfumes, on which they burned incense in honour of Jehovah; but some say it was really to sweeten the air, the common people not being very cleanly in their habits.

Arabia has for ages been celebrated for its incense, but Persia and India now furnish considerable quantities, and much is also manufactured in our pharmaceutical laboratories.

India Pale Ale. — See *Ale.*

Indian Chutney.—See *Chutneys.*

Indian Condiments.—These comprise a long list of seasonings and delicacies.

Apply to J. A. Sharwood & Co., Ltd., St. George's House, London, E.C. The largest dealers in the world.

Indian Corn.—See pp. 177, 299, 300, 474, also *Maize, Oswego, Popcorn,* etc.

Indian Figs.— See *Prickly Pears.*

Indian Meal. — Ground maize or Indian corn. An excellent feeding stuff for cattle, but on account of its peculiarly coarse flavour it is not ordinarily relished as food by human beings.

Mixed with oatmeal, however, it is highly recommended by some persons, and especially in periods of famine. (See also *Maize Bread.*)

Indian Sorrel.—A species of mallow (*Hibiscus sabdariffa*) from the flower bracts of which a jelly is made, which forms an excellent substitute for red currant jelly.

Indian Teas. — (See also *Teas, Blended Teas*, etc.)—These comprise teas grown in the British East Indies, not in the West Indies, although the latter region has been tried for tea cultivation. The total land in India under tea is over 600,000 acres, and the crop in 1894 was about 126 million pounds. The Indian tea districts comprise Assam proper (or the Brahmaputra Valley), Sylhet and Cachar in the Surma Valley, Chittagong, East and West Dooars, Terai, and Darjeeling, also Chota-Nagpur and the districts of Kangra Valley, Kumaon, and Dehra Doon. In the Madras Presidency there are also about a hundred tea gardens, chiefly in the Nilgiri (or Neilgherry) and Travancore districts.

About 96 per cent. of the tea grown in India comes to the United Kingdom, and nine-tenths of it is grown in Assam and Bengal, or about 350,000 acres in the former, and 150,000 in the latter province.

The plants cultivated are of three principal classes, viz. :—

1. The indigenous Assam (*Thea assamensis*), thought by some botanists to be the original species whence all other varieties of tea have been derived.

2. The Chinese shrub as introduced by the Government in 1834, and before the superior value of the Assam plant was recognised.

3. A hybrid between the above two.

Indian tea-planting was only started in 1835, when the Government, at immense expense, began importing into India plants from China, and which were in time spread over many districts. Only fifty years ago the province of Assam was a vast wilderness covered with jungle and swamps, the abode of tigers and other wild beasts of all kinds, but now it has become the home of an industrious peasantry. The acreage under tea cultivation, divided into some 800 gardens, exceeds 350,000 acres, and increases at the rate of some 800 acres yearly. In 1820 it had been accidentally noticed that there was a species of native tree growing in the jungle, but for years this was thought unfit for use, and it was not till 1841, when an enterprising Englishman had manufactured some tea from the wild leaves and sent it to London, that its great value was discovered. In Mincing Lane it was pronounced the finest tea ever seen in this country.

The Assam plant in growth and form of leaf resembles the myrtle. Its blossoms are nearly white, similar to our wild rose, and very fragrant. The seeds of the berries yield an aromatic oil, and instead of the plant growing only 3 to 5 ft. high, as the tea shrub in China, it attains a height of 5 to 20 ft. in the jungle, with leaves 6 to 12 inches long. These are dotted with pellucid stems, containing essential oil, the number of cells being a guide to the quality and value of the tea it will yield. It fact, the native Assam growth has ever since been considered far superior to the Chinese, richer in *theine*, and yielding a far larger quantity of leaf per acre. It is, however, more tender and difficult of cultivation than the sturdy Chinese shrub, doing best in close jungles which are, unfortunately, very prejudicial to the health of Europeans. Hence the custom began of cultivating *hybrids* from Chinese and Assam plants, and this has gone on to a great extent; but it has been found to be a great mistake, and for the last twenty-five years many planters have been trying to eradicate the Chinese variety which were imported at such great expense. This is not easily done, the hybridising being difficult to prevent. By much crossing and intermixture the gradations from one extreme to another are almost imperceptible.

About 3,000 shrubs are planted on an acre of ground, or on a slope about 6,000 of the Chinese variety. The

plant in India grows very rapidly, a new "flush" of leaves springing forth every fortnight during seven or eight months of the year, and if not gathered at the proper time they become almost valueless—the delay of even a single day may be fatal.

Within limits, the harder a bush is picked the more it will struggle to put forth new leaves. The leaves are not slipped off close to the stalk, but broken or pinched off a little above the stem, thus leaving a small portion to protect the delicate bud which grows at the angle of the leaf and the stalk, and from which future crops are expected. Unlike the slow method still adopted in China with its hand labour, Indian teas are all rapidly rolled, twisted, or sifted, cured and dried by machinery, and scarcely handled at all after being gathered. Tea-making has practically become a factory industry in both India and Ceylon.

Rolled Tea.—There appears to be an erroneous impression abroad among grocers and others acquainted with the *raison d'etre* of the different processes connected with tea manufacture, regarding the purpose for which the green tea leaf is rolled. The operation of rolling the green leaf, after it has been withered, is to give it the necessary twist or curl, and also for the purpose of breaking or rather bruising the numerous diminutive cells of which the leaves are constructed, in order to induce chemical action to take place, the result of which is the product called tea. Placing the rolled leaf in regulated layers or heaps, or making it into balls, is to promote more rapid fermentation, not to set up fermentation which would take place in any case. "Balling" is resorted to for fixing the twist of the leaf; but as the general custom is now to give a second roll to the leaf after it has fermented to a certain point, it is seldom made up into balls, being simply piled up in trays or baskets as it comes from the rolling machine. We have used the common or garden term fermentation, the more correct expression would be oxidation or colouring, for the fermentation stage is just that which has to be avoided in the manufacture of good teas.

Gola, or *Ball tea*, in Ladakh (Cashmere), is a mixture of green and black tea bound with rice-water.

Rather extensive plant of machinery is required for tea manufacture, but the whole of the operations are completed within eight or ten hours, and the cost has thus been considerably reduced.

Of course, the bulk of both Indian and Ceylon teas come to England, but increasing quantities are going elsewhere.

An advance from 14,001,132lbs. taken by outside countries in 1890 to 68,430,528lbs. in 1899 indicates the zeal of the British tea planters, and always is the best evidence that British grown teas have merits that are fast being recognised by countries accustomed to depend upon China and Japan for their supply.

The crops of India and Ceylon produced in 1899 were 305,000,000lbs., exceeding the crops of 1898 by 28,000,000lbs.

Large areas of land in India were placed under tea cultivation a few years ago, when exchange was very low. This

land is now commencing to bear leaf, and further increases of these teas may be expected for a few years.

It has, however, been complained that Indian teas are apt to contain small pieces of foreign earthy matter about half the size of peas, frequently spoiling the flavour by imparting a peculiar opium smell or bitter taste when liquored; tufts of woolly hair, finger or toe parings, high dried beetles, spiders, frogs, etc., also occasionally find their way into both Indian and Ceylon teas of the cheaper grades. (See "*Packet Teas.*") A "cheesiness" of flavour is sometimes noticeable from green or imperfectly dried wood having been used for boxes. Other chests have a cedary or drug-like odour, which soon permeates the tea and gives it an objectionable smell. As a rule, Indian teas are nearly double the strength of Chinese, but there is much difference in the former. The Sylhet teas, for instance, differ from those of Assam proper, and these again from the teas of Darjeeling, which latter are of a particularly fine character. Much of that grown in the higher latitudes of India also lacks the aroma so highly prized by connoisseurs, but being much stronger they all contain considerably more tannin (pound for pound) than Chinese and Japanese teas, producing much darker beverages. "Tannin" is held to be an objectionable property in all teas, and the higher the grade of Indian tea the higher percentage of tannin there is in it; but notwithstanding the medical outcries that have been made, it has been shown (see *Teas*) to be actually less in Indian than in Chinese, when compared with the richness of their other extractive matters generally, and the amount of leaf required for a given quantity of water.

It is keeping the tea leaves infused too long, "drawing," stewing, and boiling, that produces the excess of tannin. Three minutes is quite long enough for Ceylon and Indian teas to "draw," and five or six minutes for Chinese. Housewives and workmen should therefore be warned against these evils, also, when using Indian and Ceylon teas, to remember a less quantity of the leaf suffices. It is also important to bear in mind that Indian and Ceylon teas should be bought and sold *fresh* as possible, or that they should not be exposed long to the light and air, or they will rapidly lose both strength and flavour. On the other hand, it is said they improve very much with two or three years age if kept dry and air-tight. The rasping coarseness will be dispelled. Assam and Indian chests average about 96lbs. and half-chests 45lbs. each.

"*Java-Assam*" means tea grown in Java from Assam seed, and should not be sold as *Assam.*

Special Firms.—Indian Tea Planters' Co-operative Tea Supply Association, 6 Lombard Court, London (see advt. page 8); Jackson Bros. & Co., 14 St. Dunstan's Hill, London, E.C.; Morris and Jones, 13 to 19 Sir Thomas Street, Liverpool.

Indian Tobacco or **Gagroot.**—A common American herb, *Lobelia inflata,* growing 6 inches to 2 feet high, with numerous leaves and racemes of pale blue flowers. It is said to have been long used medicinally by the Indians and is now the officinal lobelia, with properties similar to tobacco.

Indigo. — Ar. *Med,* Da., Du., F., G., Sw. *Indigo;* It. *Indaco;* Port. *Anhil;* Sp. *Anil;* Rus. *Krutick.*

An important and valuable blue colouring matter, mostly used by dyers, artists, and laundry-blue manufacturers, but also sparingly by confectioners, etc. It is obtained from the leaves of several kinds of leguminous plants in the East Indies and China, and is a light friable substance of a deep blue colour. Nine-tenths of it comes from India, and is very powerful. The kind cultivated in Behar, Bengal, and known as *Indigofera tinctoria* is considered the best, and next to it are the *I. anil* of the West Indies, and the *I. guatemali* of Central America.

Some kinds of "indigo" are now produced by chemical synthesis, but the leguminous plant is the best source.

The *Yoruba indigo* is largely employed as a dye by the natives of Africa, but it is not yet so used in England.

The plant in Behar, which occupies about 700 Europeans, in addition to hundreds of thousands of natives, is nearly like that of tares, and the pods of similar shape. The seed, which much resembles gunpowder in size and shape, is sown in the spring in rows about a foot apart, and if kept free from weeds it grows very rapidly. In about nine weeks after sowing, and just as it is beginning to flower, the leafy stems, then 3 to 4 feet high, are all cut off with a pruning knife to within a couple of inches of the ground, another crop of leaves is ready in about six weeks, and even a third crop will grow in favourable seasons. The plant itself will last two years, but after that it is too weak, and is then pulled up and fresh seed is sown.

The leaves, similar in shape to those of the ash, are gathered into bundles, put at once into masonry vats, pressed down with wood, and covered with water, where in fifteen to twenty hours they begin to ferment, turning the water thick and green and evolving bubbles of carbonic acid gas, with traces of ammonia, and which float on the surface. The light green liquor is then drawn off into an empty vat, a little lime water is added to it, and well beaten up—this causes the green water to turn *blue* and settle to the bottom of the vat. The clearer water is next drawn off, and the pastey residuum is formed into small lumps or cakes, dried by the sun, and finally marketed. Its value in this condition is from 4/- to 6/- per lb.

The best is known by the lightness of its specific gravity and absence of earthy matter; by its assuming a fine copper-red polish when rubbed by a hard body; by its *not readily* imparting its blue colour when drawn across a white substance; and, above all, by the purity and intensity of its colour when deoxydised and made into a solution. Besides blue indigo, there are several other varieties and colours of indigo—brown, green, red, white, etc.

Artificial Indigotin.—Though the artificial synthesis of indigo was accomplished by Baeyer, of Munich, eighteen years ago, the product has only recently been available in large quantities by the Badische Anilin and Soda Fabrik for manufactuirng purposes, and it still lacks the indigo-red (indirubin, indipurpurin) so important in fixing indigo-blue on thick fibrous materials.

A quantity of indigo is grown in the Straits Settlements, especially about Singapore, by the Chinese and Malays, but lime is used in precipitating it, and this kind is generally very impure from lime and the dirty water employed.

Indigo is also extensively grown in Kwangsi, in China, and the prepared thick paste is there sold in jars containing 90¾lbs. each.

Three varieties are now being cultivated in Mexico—*I. tinctora, I. disperma,* and *I. anil.* They are made up into blocks, stamped with the plantation mark, and packed in heavy boxes, each holding 25lbs.

Infants' Foods. — See *Prepared Foods* and *Breakfast Cereals.*

Infusorial Earth.—See *Kieselguhr.*

Inga Seed or **Pois Sucrin.**—This consists of small black and bright oblong grains of flat shape, about same size as carraways, but straight and smooth, not rough or curved.

They are found in the long pods of the Inga tree, which is cultivated in certain parts of Asia and Central America, and this fruit is largely consumed by the creoles of the Antilles and Guiana, who call it "*pois sucrin.*"

Ink.—Da. *Blaek;* Du. *Inkt;* F. *Encre;* G. *Tinte;* It. *Inchiostro;* Rus. *Tschernilo;* Per. *Shai;* Port. and Sp. *Tinta;* Sw. *Blak;* W. *Inc.*

Of inks there are numerous colours and kinds; Indian Inks, Printers' Inks, Writing Inks, Copying Inks, Marking Inks, Stencilling Inks, Rubber Stamp Inks, Ticket Writers' Inks, Ink Powders, etc.

The blue-black inks of the present day consist of an extract of gall-nuts or other tannic matter in combination with an iron salt, suspended in water, containing gum, and mixed with indigo or some similar colouring matter.

The coloured inks are frequently simple solutions of aniline dyes; but logwood and other vegetable dyes are still used to a considerable extent.

Printers' Ink is usually a black paint, very smooth and uniform in its composition, and possesses a singular aptitude to adhere to paper which has been thoroughly impregnated with moisture.

Indian Ink is mostly made in China, and there are several factories at Shanghai. It is largely used as a writing ink in China, Japan, and other Asiatic countries, a small brush taking the place of a pen. Its mode of manufacture is kept a close secret, but is supposed to be merely a mixture of carbon and gum, with the addition of a small quantity of musk or Borneo camphor to give it the characteristic peculiar odour; but the manufacture is by no means easy. After the carbon and gum have been mixed, the product has to be slowly and carefully dried.

The moulding of the sticks is effected in moulds engraved on the inside with Chinese characters, such as the well-known dragon, etc., and the gilding is performed with gold-leaf. The high polish of the sticks is said to be produced by brushing them with a hard brush impregnated with tree-wax.

The fine soot produced by holding a plate over a lamp or candle mixed with clean size of parchment or glove leather is said to make an ink equal to that imported. The other inks mentioned are more fully described under their respective names.

Special Firms.—Punch Polish Co., Hick Street, Birmingham—F. Cooke (proprietor).

Insect Powders, Insecticides, etc. —There are several kinds in the market, the *Dalmatian*, *Persian*, *Buhach*, etc. Most of them are made from Pyrethrum flowers, which, in 1853, were discovered by M. Vicat, a Frenchman, to be fatal to insect life, and it was he gave them their name of Insecticides. The Dalmatian are now the most popular. They consist of the powdered flower-buds of two species of Chrysanthemum, namely, the *Pyrethrum cinerariæfolium*, a white chrysanthemum as grown in Dalmatia, and *Pyrethrum roseum*, a red chrysanthemum, native of the Caucasus.

The Asiatics south of the Caucasus kept the drug secret until early this century, when an Armenian merchant found it out, viz., that it was a certain species of Pyrethrum, growing in the mountain region of what is now known as the Russian province of Transcaucasia.

The history of the Dalmatian species still remains a mystery.

There is reason to believe that the Caucasian species is not cultivated, while the Dalmatian probably is, though no definite information can be obtained owing to the jealous watch kept over the industry.

The flower-heads should be gathered in dry weather, when they are about to open, or when fertilisation takes place. When the blossoming has ceased, the stalks are cut within four inches of the ground and utilised by grinding and mixing them with the flowers in the proportion of one-third of their weight.

Neither flowers nor powder should be exposed to moisture, air, heat, or sunlight. They should be dried under cover, and ground *fine as possible*.

The powder should be kept in perfectly tight glass vessels or tin boxes. This kind of insect powder is a specific poison to aphides, house flies, and mosquitoes (or gnats), and if used with bellows is effectual in killing the common insects that infest plants in houses.

The powder may be burnt in the treatment of rooms, wardrobes, and greenhouses.

The disadvantages of the powder are chiefly its transient effect and the necessity for actual contact with the insects when used in the open air. It has no effect on insects' eggs or hard chrysalises, on beetles with hard elytra, and on the vast class of bugs. Cater-

pillars and spiders of all kinds are also proof against it.

Persian Insect Powder used also to be made from the Caucasian flowers, locally known as "Guirila," but during the last few years many adulterated and worthless preparations have been sold as Persian Insect Powders, and the preference now is for the flowers from Dalmatia. It is probable that both kinds are equally effective, if unsophisticated, but the Caucasian and Persian growths are no longer of commercial importance. Some authorities say that the plants were all of Persian origin and only introduced afterwards into Dalmatia and the adjoining States of Herzegovena and Montenegro.

The toxic or valuable properties of the flowers are said to be mainly due to a soft, acid, resinous body (say, 4·5 per cent.) and partly to a volatile oil (say, 0·5 per cent.), both of which are present in rather higher degree (say, 5 per cent. together) in the closed or *unopened* flowers.

Trieste is the greatest trade centre for the Dalmatian flowers, which are classified and marketed as:—Small closed flowers, 60/- to 100/-; large half-closed, 50/- to 95/-; open flowers, 45/- to 75/-; wild, 40/- to 50/- per cwt. They arrive from Trieste in bales of 4 cwts. and kegs of 1½ cwts., and are sold at gross for nett weights, packages free.

The third and fourth qualities possess very little insecticidal virtue. Extreme tenuity being an important necessity, the flowers are ground into the finest powder, either abroad (in Austria) or in England. The latter is considered the more reliable, but is seldom free from adulteration. The foreign ground powders are mostly heavily adulterated, and the terms "closed," "half-open," "open," "wild," or "cultivated" flowers are quite unreliable, unless as degrees of badness.

Buhach is the name of powder made in California from the flowers of *Pyrethrum cinerariæfolium*, now cultivated near Atwater, Merced County, and ground at mills at Stockton, near San Francisco.

The plant grows about 30 inches high, and is set out in rows 4 feet apart and from 15 to 24 inches apart in the rows. When harvested, the stalks are cut just above the roots, and the flowers stripped off them by passing the plants through a kind of comb. The detached flowers fall into a box below, and are carried to the drying ground, where they are spread on sheets and exposed to the rays of the sun during the day, being repeatedly turned over in the meanwhile. They are covered during the night to prevent their absorbing moisture, as the perfect drying of the flowers is most important, in order to retain the volatile oil which gives the powder its insecticide properties. It is also very necessary that this operation should be done quickly, and that the flowers during the drying process should be protected from moisture. A slight dew falling upon the flowers at this time will injure both colour and strength. As already observed, all these insect powders are very liable to adulteration, and especially with the Hungarian daisy, Euphorbium and quillaia bark, also with the stems and leaves of the pyrethrum plant, fustic, turmeric, chrome-yellow, and other colouring matter. They may have a very pungent odour and make a person sneeze, but have no effect on insects. There is also much difficulty in distinguishing the Persian from the Dalmatian product. The unground flowers are, however, much preferred by large dealers.

How to judge Insect Powders.—Place 100 grains of the powder in the cylinder of a glass syringe (say, 1 oz. size). The powder should be pressed down compactly on to a piece of absorbent cotton to act as a filter. Then moisten the powder with ether ·735, close the top of the syringe, and macerate for 30 minutes; percolation may then proceed; the powder being re-percolated with the same fluid four times, and finally washed through with sufficient ether to make up one fluid ounce. The resulting percolate should be of a rich yellow colour; if *greenish*, it proves adulteration.

A perfect sample of insect powder should pass through a sieve having at least 80 meshes to the linear inch.

Grinding into powder costs about 3d. per lb. It should be kept close as possible and not exposed to the air, or it soon loses its virtue.

A good remedy for insects is made as follows: — Take of powdered resin 2 ozs.; caustic soda, ½ oz.; fish oil, ¼ oz. Mix in a kettle, pour 10 ozs. of cold water over the mixture, and boil for at least one hour, replacing the evaporated water occasionally.

A good way to remove fleas from dogs, etc., is to rub well with oil of aniseed. If dogs are allowed to sleep on deal shavings they will never be troubled with fleas.

Special Importers of Insect Powders.— Kimpton Brothers, 36 and 37 Mincing Lane, London, E.C.; F. Newbery & Sons, 27 and 28 Charterhouse Square, London, E.C.; C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Gardner's patent "Rapid" Sifter and Mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Insect Wax. — See *Chinese* and *Japanese White Wax*, *Shea Butter*, *Lac*, *Vegetable Wax*, etc.

Inulin.—See *Yams*.

Invert Sugar. — Ordinary sugar melted or changed back into syrup form. One kind consists of cane sugar which has been converted by acids into a mixture of dextrose and lævulose, and is called "invert" sugar because it rotates the ray of polarised light to the left instead of to the right, as does normal cane sugar. The other sort of "invert" sugar, as used by brewers, etc., is ordinary glucose.

Iodine.—F. *Iod*; G. *Jod*.

Discovered in 1812 by *Courtois*, and was first employed in a hospital in London in 1825. Large amount now made at Stavanger from Kelp or burnt sea-weed.

Irish Butter. — (See also *Butter*, *Margarine*, etc.) — There are three systems of butter-making in Ireland— first, the creamery system; then the factory system, and also the old-fashioned dairy system, where the farmer makes the butter himself.

Through the praiseworthy exertions of dairy societies, the production of butter in Ireland is gradually and satisfactorily augmenting. There are about 40,000 milch cows in Ireland and about 350,000 statute acres of pasture land, so that butter might be the staple industry. One pound of excellent butter can be produced from 2·44 gallons of milk. In past times this valuable industry received far less attention than it deserved. Cork was, and to some extent still is, the great market centre, and the merchants there were able to do so good a business that they were apparently content to let the farmers continue in the old grooves. But they were at length stimulated by the competition of Denmark and some other places abroad, where more care was given to dairy work and to the preparation of the consignments for market. This opposition has had a salutary effect, for blending mills and creameries are to be found scattered over Ireland now, to receive and deal with the produce of the surrounding farms. (See *Blended Butter*.) As to whether the Creamery or Blending system is the best for the Irish farmers, there appears to be divided opinion, but in Cherbourg, France, where both have been tried, the preponderance is in favour of butter properly made by small farmers being collected at the weekly market towns, and afterwards blended by the exporters. In Ireland the larger farmers appear to be sending their milk to the creameries, while the small cottiers find it best to sell their butter to the *Blending factories*.

The introduction of the creamery and hand separating system, as well as the adoption of the factory system and improved methods of dairying as taught at the Glasnevin and Munster dairy schools, under the able supervision of Professors Carroll and Smith, have brought Irish butter to a much higher state of excellence and uniformity. Upwards of 200 steam dairies and numerous blending mills are already at work in that country, and, with its equable and moist climate, the ancient prestige of Ireland for finest

butters should soon be recovered. Four-fifths of the farmers in Munster rely mainly upon their butter for meeting their rent and other important obligations.

The Irish grass butter season begins usually in April, and closes in November, and during that period the cows are fed in the open, and the best butter obtained. It used to be mostly packed in firkins, but is now largely exported to England in small packages of fresh prints and rolls, or preserved in tins for hot climates, for which it is found very suitable, and retains its good qualities unimpaired for a long period. Assuming that Irish butter can hold its own against all other imported kinds—and this is not impossible to a country whose humidity gives rich pastures—every firkin available for export would find a purchaser on this side of the Channel; and we need not point out the effect of a material increase of the supply upon the prosperity of Irish producers.

In the three southern provinces of Ireland the cream is churned as in England, but in Ulster, from time immemorial, the habit of churning the whole milk has prevailed. The chief drawbacks to Irish butter are careless and unattractive packing, lack of uniformity in the qualities, smokiness of flavour, arising from the peat fires in Irish cabins and farm-houses, and *excess* of *water*. Since the introduction of special machinery by butter merchants for mixing butter and breaking up the globules at the blending factories, it has been found easy to incorporate 20 to 30 per cent. of water, and a class of persons, known as "butter slachers," are thus doing the trade serious injury. Butter which seems to weep most does not always contain the most water. It is all a matter of temperatures during the churning and machinery, and it is possible to produce butter with 30 to 35 per cent. of moisture, that, when cut, will not show a thimbleful; whilst others with only about 12 per cent. will give off water at every cut.

A report of an investigation carried out for the Munster Dairy and Agricultural School, Cork, in order to ascertain the proportions of water contained in Irish salt butter, was issued in 1896. The butter examined was that of the Munster School, an estate on which it is well made, a co-operative dairy, and a number of tenant-farmers' dairies. The dry-salting and pickling processes were separately examined, and the examiners reported in favour of the former, as equally effectual in preserving butter, while much less liable to introduce an excess of water. Out of 164 samples of dry-salted butter only three contained 19 per cent. of water or more, while only five contained over 17 and under 18 per cent., and 120 ranged from under 10 to under 15 per cent. The average was only 11·95 per cent. The average proportion of water contained in a number of samples brined at seven different temperatures was 26·44 per cent., and the range was 17·03 to 42·62 per cent. The latter extreme was that of one lot of butter salted in brine at a temperature of 105 degrees. It is therefore evident that when dry-salted butter is worth 1/- per lb., pickled butter would be worth only 10¼d. per lb., supposing the proportions of water shown above to be representative.

The Cork butter marks are / for Firsts, X for Seconds, H for Thirds, and -H- for Fourths.

There is only one standard but no less than seven grades, viz., *three* in slightly salted butter, and *four* in the heavily salted.

In 1896 the trustees of the Cork Butter Market raised the qualification for all grades, also introduced new brands, known as "Choicest Mild Cure," "Primest Salt," "Choice Mild Cure," and "Prime Salt."

These brands bear the daily date of inspection, and are now arriving in the market in best condition, and in increased supplies.

The "Choicest" and "Choice" Mild Cure are packed in either firkins or pyramid boxes, weighing not less than 55lbs., or more than 57lbs. of butter, and in smaller boxes of not less than 27lbs., or more than 29lbs. of butter.

The "Primest" and "Prime Salt" butters are packed in firkins of white

oak, white hooped, and fully bound, weight of which is not to be less than 55lbs., or more than 57lbs.

Cleanliness is assured by having all branded butters leaving this market wrapped in parchment paper, and every package covered with canvas.

Irish Moss.—See *Carrageen.*

Irish Whisky.—See *Whiskies.*

Isinglass. — Da. *Hunsblas;* Du. *Huisblad, Vischlijm;* F. *Colle de Poisson, Carlock;* G. *Fischleim, Hausenblase;* It. *Colla di Pesce;* Lat. *Colla piscium;* Port. *Colla de peixe;* Rus. *Ichthyocolle, Klei Rubüi, Karluk;* Sp. *Cola de pescado;* Sw. *Husblas.*

A whitish dry leathery semi-transparent substance twisted into several shapes, but often cut into fine shreds. It is often prepared from the air-bladders and sounds of various species of *Acipenser*, or other large fish.

But true isinglass is made from the air-bladders of sturgeons only, and is a tissue dried and cured, but which has *never been dissolved.*

In removing the eggs from the sturgeon for caviare in Russia, the swimming bladders situated above the dorsal spikes of the fish are plunged in water and separated from their external skin, cut lengthways, covered with cloth, softened by the action of the hands, made up into tablets or small rolls, and these constitute the true isinglass as imported.

It used to all come from Russia, but is now imported from several points—East India, North and South America, etc.—although the Russian is still considered to be the best.

Brazilian Isinglass from Para, is made from the air bladder of the *Sudis gigus*, common in the river Amazon, and is of a reddish brown colour.

Isinglass dissolves readily in hot water, and is used for a great number of purposes, such as clarifying beer, wines, liqueurs, etc., preparing creams, jellies, blancmange, etc. With silk it is made into "court sticking plaster," and with gum is used for stiffening and adding lustre to gauzes, linens, and silks, varnishing, and glueing delicate objects.

Probably there is nothing that is more extensively adulterated than Isinglass, which is not gelatine, but a natural product, viz., the air-bladder of the sturgeon cut into very fine shreds; whereas gelatine is obtained by boiling animal matter, and costs considerably less than Isinglass—hence the adulterations.

The following simple test will enable those who feel an interest in ascertaining the purity of their purchases to do so, viz. :—Cold water being the natural element of Isinglass, it is insoluble in it, and retains its thread-like form without materially swelling; while fine-cut gelatine and other preparations sold as Isinglass, if subjected to the same process, will swell and partially dissolve.

The result is reversed by using vinegar and water, for then the gelatine and imitation Isinglass will be practically insoluble, while the genuine Isinglass will swell and readily dissolve into a jelly-like mass, leaving no traces of its original form.

To detect the difference between Russian and Brazilian, pour boiling water on each of these kinds, and this result will be produced, viz. :—Russian will become a comparatively clear liquid, and Brazilian a very opaque milky solution.

Good Isinglass is also unchangeable in the air; the clearest is best. It is sometimes adulterated with gelatine, and should always be tested before purchase. Over 100 tons of Isinglass are imported every year.

Isinglassine is a pure, nutritious, and economical substitute for real Isinglass, which article is rather expensive.

Isinglassine is manufactured only by the patentees, Messrs. Gridley & Co., the well-known Isinglass merchants, of Bishopsgate Avenue, London. The retail price is 6d. per packet, sufficient to make a quart of brilliant jelly.

Islay Malt (pr. *iss-lay*).—A celebrated kind of whisky distilled in the island of Islay, on the west of Scotland.

Italian Butters.—In Italy butter is only produced in four districts—in the plains between the Alps and the Po, in the Tyrol, in the districts of Reggio, Emilia, and Sorrento,

The best qualities come from Lombardy, and the prices are regulated by the Milan market. The butters of Reggio and the Tyrol are used mostly for mixtures, and the Sorrento products are disposed of on the Naples exchange. In the other Italian provinces oil is generally used instead of butter.

Italian Cheese.—The best known of these is the "Grana" (or Parmesan cheese), so-called from its granulated texture. Next come the "Gorgonzola," "Emmenthal," and "Stracchino" of Lombardy, the "Fontina" of the valley of Aosta, and the "Cacio Cavallo" of Rome and Southern Italy. The latter is, however, produced on a small scale also in Lombardy. In shape grana cheeses are round, have an average depth of 8 inches, and a diameter of 2 feet. Those produced at Parma, Reggio Emilia, and Modena weigh from 44lbs. to 132lbs., with an average of 80lbs. In Lombardy the cheeses weigh from 110lbs. to 156lbs. and even 200lbs. One hectolitre of milk yields from 5·50 to 5·85 of butter. Grana cheese cannot be exkilos. of cheese, or 2·25 to 2·50 kilos. posed to an elevated temperature without injury, yet it stands long journeys if properly packed. The principal centres of production are the provinces of Milan (Milan, Lodi, Codogno), Como (Lecco), Pavia, Reggio Emilia, Parma, Belluno, Modena, in the north of Italy where abundant pastures for the feeding of cattle are always available. Generally, no preservative is employed but the common salt, which is added to butter when exported. Many of them are preserved in brine, and are exceedingly salt. Some large exporters of Venetia and Lombardy, however, employ a special salt obtained from the mines of Lungro (Calabria Citeriore), which, although more adapted than common salt, is said to be still inferior to the salts of Egestorff, Lüneburg, Stade, and Linden, employed abroad for foreign cheeses of a superior quality. Its chemical composition is the following:—Chloride of sodium, 97·69 per cent.; sulphate of calcium, 0·06; chloride of magnesia, 0·05; chloride of calcium, 0·15; sulphate of sodium, 1·40; water, 0·21; insoluble matter, 0·44. This salt is found in blocks and ground for use.

From Sicily a limited quantity of a mediocre quality, but of a peculiar flavour, is exported to satisfy especial tastes of Italian residents in Trieste, Constantinople, England, and France. In Piedmont, Romagna, and Tuscany also, some good cheeses are made.

The whey that remains after the cheese is made is generally utilised in Italy to make the "ricotta," which is produced in the following manner: The whey is heated up to 80° C (176° Fahr.) and worked up with the "follatoio," a long stick, to the end of which a round wooden disc is affixed. In less than an hour the "ricotta" appears on the surface of the liquid, and is collected and placed in baskets to dry. The ricotta is either eaten fresh or else is salted and dried in the oven, when it is used by the peasantry as cheese.

To make a "*firma*" per diem, which is a large cheese weighing from 1 to 2 cwt., not less than 50 cows are required, and on some farms as many as 120 to 150 head are kept. When the cows on the farm are few in number, the owners either join together for the purpose, or sell their milk to the professional cheesemaker. The "Casaro" or cheesemaker among the peasantry stands in a better position than other workers. The "Casari," indeed, may be said to form a species of caste, and they surround their craft with as much mystery as possible.

Their wages in money and kind equal from 2 to 3 lire a day. They are fully conscious of their importance as the arbiters of the most valuable product of the country, and are held in great consideration by the farmers, with whom they treat as equals.

Italian Paste.—F. *Pâtes alimentaires;* Port. and Sp. *Pasta Italiana.* (Also known as *Genoa, Neapolitan,* or *Naples Paste,* etc.)

A peculiar preparation of wheaten flour, produced only in South Italy and Sicily until recent years.

Similar pastes are now made from Taganrock, African, Auvergne, and

ordinary wheats in France, especially around Lyons, Marseilles, and Auvergne, also in Trieste and some other countries, from semolina or ordinary flour, which latter is, however, much less suitable, but it is made in greatest quantity on the coast of Genoa and in the Neapolitan Provinces. About half the Italian export goes to America and the rest to France, England, Austria, Turkey, and Egypt.

In Sicily and Naples it is made in great perfection, and forms the staple food of the people. The best is made in Genoa, where it is prepared from the hard red and most glutinous sort of Italian or Russian wheat. The kind is known as *grano duro* (hard wheat), and was originally imported into Italy, from Taganrock, the neighbourhood of the Black Sea, about four centuries ago.

This hard and highly nitrogenous wheat is first washed and then ground up into a coarse meal, or *semolina*, which, when dressed, the husk or bran and coarser parts of the grain being removed, is pure wheat flour. It is then mixed with water and well kneaded, either by hand or in heavy wooden blocks worked by powerful levers, till it forms a very tenacious paste. This is put into a cast-iron barrel or cylinder, somewhat like a cullender, which has a perforation of small crescent-shaped holes at the bottom. Pressure is applied at the top of the paste by means of a plate of iron and a screw piston, forced slowly through the holes at the bottom in continuous streaks, the pressure employed in some factories being over 3,000 pounds to the square inch.

As they descend, the crescent-shaped streaks shrink and come together, and being moist they unite and adhere, thus forming long, slender, hollow tubes or pipes.

These tubes also dry as they descend, and are then received by the work girls, nipped off, and twisted into the desired shape. Some kinds are put through wire gauges with or without mandrels, as in wire and pipe drawing, and a fire under the cylinder dries or partly bakes the paste as it descends. (See *Macaroni*.) This kind of paste is, in fact, made into a variety of sticks, lozenges, disks, ribbons of several sizes and forms. After being cut or twisted into the desired shape, the product is then further dried on wooden rods till quite hard and crisp. It is sometimes made into flat ribbons or fillets by being pressed through flat holes.

Italian Paste is thus the generic term for a great number of forms which it assumes, such as *Macaroni*, *Vermicelli*, *Fedelini*, *Sparghetti*, *Mostachiola*, *Reginette*, *Ditalini*, *Zita*, etc. (See also *Lazagnes*, *Cagliari*, *Glutinata*, *Pastina*, *Strichetti*, *Tortellini*, etc.)

They are all made from the same kind of paste, as above described, and merely take their form from the size and shape of the holes at the bottom of the metal cask or cylinder employed.

The dough is sometimes rolled into thin sheets and stamped out into little stars, rings, letters, figures, and other curious, elegant, and fancy forms (see *Pâtes Alphabétiques*); but the most approved method of making these now is to pass the paste through a cylinder with a piston working horizontally. The apertures then have the shape of the star, cross, etc., and revolving knives working just outside the cylinder cut the slices as the mass emerges.

The lightest coloured pastes are usually preferred, although that is a mistake. White pastes should, in fact, be avoided, as they are not the product of honest manufacture. The red colour of the proper grain imparts a brownish tinge to the genuine paste.

Genoa paste is occasionally coloured with a little saffron, but picric acid—a very injurious substance—has been detected in some imitations.

Naples paste is usually made in straight pipes, thicker than Genoa, and is about a penny per pound cheaper.

The use of these pastes, or *pâtes*, is rapidly and deservedly extending throughout the world. Care must be taken to procure them new and fresh as possible, and not to keep them on hand too long, or they are apt to turn rancid, mitey, or weavilly. Sometimes by

absorbing moisture they go mouldy or musty. They are best judged by the smell, and should be kept in a cool, dry place, and it should be remembered that the best qualities, being richest in gluten, are the most easily fermented and spoilt. The finer qualities arrive in square chip boxes of about 4lbs. each, but while Vermicelli boxes often contain a few ounces *over*, Macaroni boxes are usually *under* this weight. It is, however, a custom of the wholesale houses to buy them all at actual weights, and sell them to retailers at nominal weights.

Italians say this paste is as a rule disgracefully served in England. The pipes should *not* be broken up small, but boiled to a nicety and without being burst. Time is wanted more than heat.

Thousands of small factories (many of them very dirty) are scattered throughout Italy, which are operated entirely by hand, but the larger establishments are carried on by steam power.

Importers.—Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Italian Wines. — These are very numerous, but principally made for home consumption. The sparkling kinds differ from those of other countries, being less effervescing. There are some boiled varieties, but they are not much known. Tuscany is deemed better as a wine district than any other part of Italy, and the best sorts are *Chianti* (a red wine grown on the estate of Baron Ricasoli, and rather popular in England) and *Monte pulciano*, which latter is made from a mixture of ¾ black with ¼ white grapes.

The mode of bottling in Florence has given rise to the term "flask of wine," these wine flasks being almost identical with those in which oil is exported, but of larger size. Sometimes a little oil is placed on the top of the wine in bottle, and then stoppered with only a little plug of cotton-wool instead of a cork, in the old Roman fashion.

The layer of oil is to keep the wine free from the air. When, however, the wine has to be used the oil must be got off, and the usual method of removing it must be seen to be appreciated.

However carefully done, enough oil is left behind to flavour the whole and make it objectionable to those who do not like oil.

The annual wine yield in Italy is about 450 million gallons; in 1895 it amounted to 21,343,000 hectolitres, as against 25,816,588 in 1894.

The falling off is attributed to the rains falling at a moment favourable to the incursion of cryptogamic disease.

The largest quantity is produced in the Southern Adriatic provinces. Sicily comes next, then follow the Mediterranean provinces, Tuscany, Emilia, Piedmont, Lombardy, Venice, The Marches, and Sardinia.

The chief kinds are:—*Sparkling:* Asti (red and white), Nebiola, Logrimo, and Passeretta. *White:* Malvasia or Vino Santo, and Vermuth.

Other kinds are:—Monte Fiascone or Est Est, Montelcino, Santo Stefano, Rimaneze, Vino Greco, and Chaumont.

Monte Pulciano, a sweet and somewhat astringent wine of purple hue, is considered one of the best.

Antella, Artimino, Carmignano, and Poncino are also very fair kinds.

Verdea, of greenish colour, is made in Arcetri, near Florence.

Trebbiano is a syrupy kind, of golden colour.

Lachryma Christi is a rich red wine of Naples, and both Albano and Orvieto resemble it very closely.

Capri Binuro is a fish or oyster wine, and has a bouquet entirely its own.

Valtellina resembles Medoc, but has a much fuller body of wine.

Barbera, Barola, Inferno, Lambrusco, and Braccheto are great favourites with Italians.

Muscadenes and dry wines are mostly made at Reggio.

Asprimo is white and foamy, with sharp taste.

Carigliano has a flavour of fennel.

Aleatico, Giro, Malvasia, Vino Santo, Bosa, Ogliastro, and Sassari are all produced in Sardinia.

In Italy the vines are allowed to follow their natural mode of growth, and are simply trained picturesquely

amongst trees and on trellis-work. In other countries, where the culture of the grape has been scientifically treated, the varieties have been astonishingly multiplied; but it is surprising how small is the change that the lapse of time has brought into the culture of the vine in Italy. On reading the usages of the ancients, it appears the plant is still grafted and managed there as it was in the time of Varro, author of *De Re Rustica*, who died 28 B.C.

Ivory Black.—See *Charcoal*.

Izal.—The registered name of a disinfectant. It seems to consist of tar acids made into an emulsion by means of gelatine.

J

Jaffa, or Joppa Oranges.—From Jaffa, or Joppé, an ancient seaport on the Syrian coast, near Jerusalem.

Eighty per cent. of the crop, from 200,000 to 350,000 boxes, holding 80 to 160 fruits each, and weighing about 84lbs., is shipped to Liverpool, and nearly all the rest goes to London and Glasgow, through the agency of British subjects on the spot.

The superiority of the Jaffa oranges for both size, sweetness, and flavour is world-renowned, and the consumption in England yearly increases.

Their colour is paler than the Spanish fruit, but a special feature of them is that they will keep thirty to forty days, and, if properly packed, for two and even three months.

Their cultivation has been carried on many centuries about Jerusalem, in Palestine, but until about 1875 the fruit was known only in Beyrout, Alexandria, and Constantinople. The industry now finds employment for a very large number of men and boys, and is regarded as one of the chief sources of income for Jerusalem and Jaffa. The area at present devoted to the orange culture is only about 3,000 acres, and cannot well be much increased, but the Jewish settlers in the colony of Petah-Tikva are planting a large part of their grounds with orange trees. There are in the plains around Jaffa some 500 gardens, containing about 800,000 trees. In Palestine (both about Jaffa and Gaza) the orange trees never suffer from any noxious insects, fungus growth, or disease of any kind, and both climate and soil are admirably adapted for producing healthy trees; but the groves require to be artificially watered from May to November, and the system of irrigation is one of great antiquity. There was a time when Jaffa oranges, as an article of commerce, used to be exported to Russia, Austria, France, and to various parts of Turkey. Later on small quantities were sent to Liverpool and London, and had to be transhipped at Port Said and Alexandria; but in consequence of injuries received whilst being transferred from ship to ship, and the long time it was on the way, the fruit suffered much, and was in a bad condition by the time it reached its destination. Since, however, the steamers of the Prince Line have begun plying directly and regularly between Jaffa and Liverpool, and English merchants have empowered their agents to advance money to the shippers, the orange trade with England has so developed that what is now sent to Liverpool alone amounts to 80 per cent. of the crop, the freight to that port being but 1/6 per box. By this arrangement the natives find themselves in the satisfactory position of being able to dispose of their fruit at a good price, and the English merchants also make fairly good profits, and the trade cannot help thriving.

Oranges and lemons are also exported in large quantities from Sidon, North Palestine. This fruit is usually packed in boxes containing from 200 to 300.

Jaffna Moss.—See *Ceylon Moss*.

Jaggery Sugar.—A rough coarse kind of brown sugar, resembling crude

Maple sugar, and obtained in Ceylon and India by boiling and evaporating the juices or saps of certain palms, such as the gommutti, cocoa-nut, kittool (*Caryota urens*), palmyra, and especially the date palm (*Phœnix sylvestris*) which often yields as much as 180 pints of sap, or over 100lbs. of sugar. The caste who prepare this sugar in Ceylon are known as Jaggeros. The kittool palm also yields a bastard sago, and a fibre called Elephant fibre or Indian "gut," commonly used in making fishing lines, brushes, etc., and is the nearest approach to bristles.

Jaggery is frequently formed into small round cakes, and exported in mats. It is very like cane sugar, and often sold as such; indeed, after refining it is almost impossible to distinguish it from West India cane sugar.

Children should be warned against eating it, especially in our seaport towns, where it is often exposed on the quays and wagons on its way to the refineries, for it is generally full of beetle-like animalculæ, invisible to the naked eye, but which have been known to eat the stomach and intestines so as to cause death from *peritonitis*, by inflaming the bowels.

Jalap. — A popular purgative, taking its name from Xalapa, in Mexico, and obtained from the roots or tubers of an Indian plant known as *Ipomœa purga*. As cultivated in Madras, Ootacamund, Jamaica, etc., the tubers are planted in rows on ridges a few inches high to prevent water from becoming stagnant around them. The plants, being of a climbing nature, require stakes or trellis, like peas. The stems die down annually, and the tubers remain dormant for two or three months. One acre of land will yield at the expiration of three years about 5,000lbs. of green tubers, which, when thoroughly dried, give 1,000lbs. of jalap powder. The consumption in the United Kingdom is about 200,000lbs. annually, chiefly imported from Mexico, *viâ* Vera Cruz.

Jam. — F. *Confiture*; G. *Conserve*; Port. *Doce*; Sp. *Dulce*. (See also *Preserves*.)

The manufacture of jam has undergone a great change these last few years, and England is now, thanks to cheap sugar, the greatest jam-making country in the world. It used to be a common practice to bruise or pulp the fruit and pass it through a small sieve before boiling it; but now the cheapness of sugar, coupled with the fancy for "whole fruit" jam of bright and fresh colour, has quite revolutionised the old style.

Instead of pulping the fruit, using very little sugar, and boiling a long time, thereby spoiling the colour, form, and flavour, it is now the rule to use more sugar—good loaf or crystal—bring the jam to boiling point as quickly as possible, and then boil rapidly and only for a very short time. Cane sugar is by far the best. No manufacturer who knows his business will use *beet*, no matter how beautiful or cheap it may seem. In most of the modern factories it is boiled by steam at a pressure of, say, 30lbs. to the inch. By this process the watery portion of the fruit is evaporated in some seven to ten minutes, and the steam-jacketed pans being very large, one or two hundredweight of jam is perfectly boiled in a single pan in a marvellously short space of time. The steam being turned on and regulated by a tap, boiling commences quickly, and is continued slow or fast as desired. It has also been found that there is no profit in using cheap "pieces," or raw sugars, as they lose considerably in weight in boiling, taint the flavour, and deaden the colour of the jam. The superior sugar, moreover, congeals much better, forming with the juice an excellent thick jelly.

As already stated, the results aimed at nowadays are the preservation of the natural colour and form of the fruit and the thick jelly-like syrup; but every jam firm has, of course, some process of its own by which it professes to obtain better and more showy jams than its competitors. Some prefer

"real jam," with the fruit in a pulpy mass. This is effected by passing the fruit—currants, raspberries, strawberries, etc.—down a hopper into a wire-woven cylinder, inside which brushes revolve, pressing against the wires, the pulp being squeezed from the fruit, and the stalks turned out as clean as if washed. Boiling pans should be made of copper or bell metal, and be kept bright. Silver has been tried, but the inherent acid of the fruit is apt to form a chemical compound with the ore, and does not answer well. Iron, zinc, or tinned pans or utensils should never be used; they discolour the product and impart a metallic taste.

The fruit should be neither too ripe nor too green; if the former it boils tough, the colour is also dull, and the juice remains syrupy instead of changing into a bright jelly; if too green it boils sloppy and tastes of the tree. (See *Green Fruit*.)

If the fruit is to be pulped and stored in bulk the casks or stone jars in which it is filled should be thoroughly cleansed and "sulphured." Break up a little bar sulphur, put the pieces in an iron pot (similar to one in which tar is melted), stand the pot on the top of a hot furnace plate, and let it remain until the whole of the contents become liquid. Have ready a few strips of unbleached calico; then take a strip and dip half its length in the sulphur, light it, and let it down into the vessel, and bung loosely (not too tight), leaving the undipped end of the strip outside.

In a few minutes, according to the size of the cask or jar, the burning sulphur will exhaust all the air, and the rag may be withdrawn. The bung must then be replaced tightly until the vessel is wanted for use. The sooner the hot pulp is put into it and the bung driven fast in the better.

The principal fruits imported from foreign countries are red currants, black currants, plums, cherries, greengages, and French apricots. Very few strawberries or raspberries come from abroad, and these jams are consequently nearly all made from British fruits. Some raspberries are, however, imported from Canada. In the Clydesdale district, Scotland, there are about 250 growers, occupying 3,000 acres of land, about half being laid out in strawberries. Black currants are mostly grown in England, very few in Scotland.

Manufacturers have been charged with using almost all kinds of abominations to adulterate jam; some critics are quite sure that turnips, carrots, and other vegetables are commonly used; but the idea is quite absurd, and if those illogical libellers would just try to produce or cheapen jam with such substitutes many of these fine old crusted delusions would the sooner be eradicated from their minds.

Some manufacturers, however, do frequently use cheap damaged fruit, also fruit pulp which has been deprived of most of its juice, for making syrups, jellies, and fruit essences; the bad colour of the damaged fruit being artificially coloured with aniline or coal-tar dye, while the exhausted pulp, rich in seeds but defective in juice and flavour, is generally boiled with a special kind of grape sugar, or *liquid glucose*, this thick factitious syrup partially supplying the place of the natural juice extracted.

A little glucose, say 5 per cent., is undoubtedly an improvement, but when manufacturers put in 20 to 50 per cent. it amounts to a fraud on the consumer, for the glucose and water is only worth about a halfpenny per pound.

It cannot be denied, also, that in several of the low-priced mixed jams, fruit preserves, etc., sesame or gingelly seeds are introduced to represent the seeds of raspberries and strawberries, while apple pulp of even vegetable marrow is actually the predominating ingredient, although two or three raspberries, strawberries, or gooseberries may appear near the surface of the jar. It is, moreover, undeniable that old figs, and other dried fruits which have become unsaleable as such, have been frequently used in the manufacture of

jam. Boiled sago, rice, and similar farina, heavily coloured with logwood chip or other dyes to represent fruit, are largely employed by the makers of 'arts for poor children in low neighbourhoods; but this cruel deception is generally the work of certain unscrupulous pastry manufacturers to be found in most of our large towns, and who make it their special business to supply the smaller general shops.

Almost every housewife prides herself on her jams, jellies, and preserved fruits, but it is very rare that these come up to trade standards of excellency. Old kitchen processes may do for home use, but are far too slow and costly and uncertain for supplying the wants of the world to-day.

With the exception of raspberries it is often difficult or impossible to tell at sight what fruit home-made jams have been made of; the colour is lost, and as a rule the jam is sadly over-sugared and over-boiled. The prevalent notion is that the more sugar it contains and the longer it is boiled the longer and sounder it will keep, but, as shown under "*Fruit Jellies*," the *pectine* is thus ruined and lost. Then, as to the proportion of cane sugar to be added to the fruit. No set rule can be fixed. Much depends on the state of ripeness, and certain fruits—such as grapes, mirabelles, plums, apricots—when fully ripe, contain quite sufficient sugar in themselves, without any further addition.

If jam be boiled over a fire the pan should never be placed flat on the fire, but on a trivet, or hot plate, or the contents are liable to burn. Precaution should always be taken never to add fresh fuel to the fire to finish boiling a panful, or the heat will be checked, smoke caused, and over an open grate the flavour of the jam probably spoilt. A clear fire and good sharp heat is best when steam cannot be employed. The long time required for boiling jam over the fire is one reason why such jam is often noticed to be covered with sugar that has become granulated and has caked on the surface.

Another frequent cause of this granulation is the use of too much sugar, or sugar in large ungainly granules; besides, there are in fruit as well as in sugars active nitrogenous substances which at a temperature considerably below boiling point rapidly convert the sugar into lævulose, etc., which, if the jam be kept, soon crystallise, and give it the appearance of fermentation.

To prevent candying or incrustation most manufacturers add grape sugar, or *glucose*, after boiling, and some a small quantity of gelatine, which gives firmness and coherency to the mass; or, when the jam is potted and set, slightly oil the surface with a little olive oil. Some people use spirits, others rely on making the pots air-tight, but neither of these latter precautions are necessary.

To prevent mould forming at the top of preserves soak the thin paper circles and parchment covers in a solution of salicylic acid and borax, say 60 grains of each dissolved in a pint of hot water, or a solution composed of 1¼ ozs. of formalin to 1 gallon of water will answer the same purpose.

Fermentation mostly arises from insufficient boiling, unsound fruit, or careless and defective covering, by which air is admitted.

Under the name of each kind of fruit may be found further details on the jams and jellies made from them (see page 111). It must be evident to all that steam boiling, honestly done, with cane sugar, makes better and brighter jam than can be produced over the open fire, and that manufacturers dealing with large quantities can thus produce finer and cheaper jam than is ordinarily possible on a small scale by housewives, who generally use beet sugar.

An increasing number of retailers now boil their own jams. The necessary plant is not large or expensive, the quality of the home product can be guaranteed, and it is one of those articles that can be sold at a better profit.

Mixed Jams.—To avoid fines these require cautious labelling, either as (1) "Mixed Jam," (2) Fruit Preserves, (3)

Pure Jam, Raspberry flavour, or else (4) each kind of the fruit used must be clearly named.

Care and good taste is necessary in mixing fruits—red currant and raspberry, raspberry and gooseberry, gooseberry and strawberry, dates and peaches, fig and rhubarb, go well together; also certain combinations with apple, but pears with gooseberries would be horrid.

Apply to Morris & Jones, Sir Thomas Street, Liverpool; and for articles for jams, C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Jamaica Coffee.—A rather large yellow berry, tinged with green. The best is a little stronger than Java and milder than Rio. Inferior samples are of mixed colours, often pale, and the berry flat, liquor thin, but generally possessing a delicate flavour.

Jamaica coffee, like that of Haiti, is mostly of fair quality, and about 25,000 acres are devoted to its culture. The best is raised in the parishes of St. Andrew and St. Thomas. Jamaica exports altogether about 1,000,000lbs. of coffee yearly. Half of it—and that of the better qualities—comes to England; and the other half, mostly cheap and inferior growths, goes to the United States.

In the larger plantations the trees are planted only about 6 feet apart, and by cropping and thinning are not allowed to grow over some 4 feet high.

Jamaica Ginger.—This is the finest ginger known in the market, and realises the highest prices, the best being known as *Plant Ginger*.

The cultivation of ginger in Jamaica, the largest of the British West India Islands, has long received special attention, and it has been found that the production of the best depends largely upon the ground in which it is grown, the deep black soil of the virgin forest being most favourable to it. When the soil has become too poor to grow yellow, or "Plant" ginger, then blue, or ratoon, ginger, an inferior variety, is cultivated. Locally the root is classed as "blue" or "yellow," depending upon the colour of the flowers of the plant from which it is derived. The two plants are botanically identical, but the "yellow" root is said to be better in quality.

Each of these classes is, as stated, divided into "plant" and "ratoon" ginger, the former being the rhizome from plants of the same season's growth, and the latter the rhizomes of plants left in the ground from the harvest of the previous year.

The drying, however, is of more vital importance than the growing, and in wet seasons an evaporator has to be employed to drive off the moisture.

The ginger is harvested just after the stem of the plant has begun to wither, the roots being dug out of the soil and then freed from earth by washing with water.

They are then soaked in water for some time as a preliminary to "peeling," which operation requires great care, as only the outer rind must be removed, or a loss of the pungent volatile oil will ensue. The peeling is mostly done by experts with a simple knife. Peeling machinery have proved a failure. It is customary to have "peeling matches," in which the planter gets all his friends to join, and there is much merrymaking in the sable community. After "peeling" the root is once more washed and then dried in the sun.

No artificial bleaching agent, such as sulphurous acid or chlorine, is at present made use of in Jamaica.

It should have a pale buff hue, a striated and fibrous surface; should break easily, exhibiting a short farinaceous fracture with numerous bristle-like fibres.

The average yield of dried and cured ginger, fit for the market, in Jamaica, is from 1,000 to 1,500lbs. per acre. A good crop may yield even 2,000lbs. As long as the ginger, when dug up, is kept from the sun, it need not be peeled for two or three days. After peeling for the day the roots should be put to soak in plenty of water over night; in the morning washed, cleaned,

and weighed; then put on mats and turned over carefully at midday, and taken in at nights for six or eight days until cured. It takes 3lbs. of green ginger to make 1lb. of dry root. The purer the water the whiter is the product. Sometimes lime-juice is used in the wash-water, which gives a whiter root; but as the lime-juice contains saccharine matter and pectose it prevents drying, and mildew may follow.

When the crop is fully dried it is caried, mostly by women, to the place of sale, which may be from five to forty miles distant. Here it is sold by the "heap," not by measure or weight. A "heap" of ginger varies considerably, according to the law of supply and demand. If the "hands" are finely shaped and large there are fewer in the heap; if small, dark, and snarly, the pile is made larger. Should the price of ginger in London or New York advance it is because the heaps in Jamaica have been diminished, and should the price go down the heaps have become larger. The exporters of ginger assort the produce into four or five grades, the highest being the large-sized hands of light and uniform colour, the lowest being the ratoon finger sorts, which are small, soft, and lacking flavour. Some of the hands weigh as much as 8 ozs.

The following figures represent the exports of ginger from Jamaica for four years:—In 1893, 1,526,884lbs.; in 1894, 1,672,384; in 1895, 1,736,460; in 1896, 1,960,609lbs.

Special Importers of Jamaica Produce.—The Pure Cane Sugar Co. (J. Philip & Co., agents), 4 Fenchurch Buildings, London, E.C.

Jamaica Pepper, or **Allspice.**—Old-fashioned names for *Amomi*, or *Pimento*, which see.

James's Powder. — A patented medicine, consisting of one part of oxide of antimony and two parts of phosphate of lime, mixed and given in doses of 3 to 10 grains

This is one of the commonest and safest forms in which antimony is used.

James's Tea. — Prepared in North America from a species of Erica, *Ledum latifolium.*

Japan Black.—Used for japanning leather goods, etc.; one kind is flexible, the other inflexible.

(1) 4 ozs. burnt umber, 2 ozs. asphaltum, and 2 quarts boiled oil. Dissolve the asphaltum in a little of the oil, add the burnt umber, ground in oil, then mix with remainder of the oil, cool, and thin with turpentine.

(2) 1 part shellac, 4 parts wood naphtha; dissolve and colour with lampblack.

Speciality.—Paton, Calvert, & Co.'s "*Komo*" Black Enamel for grates, etc., Leeds Street, Liverpool. (See "*Komo.*")

Japanese Cement.—A kind of *Rice Glue*, made by mixing rice flour with cold soft water, and then boiling until thick. It dries nearly transparent.

Japanese Date Plums.—See *Kaki.*

Japanese Isinglass (*Agar-Agar*).—A name given to several species of edible seaweed, of which *Gelidium spinosum* is the chief. It contains about 50 per cent. of gelose, and will gelatinise a larger quantity of water than any other known alga.

It requires rather a higher temperature to melt it, and is not therefore very readily soluble in the mouth, but it is often used in the preparation of the cheap jellies made for sale in the shops. It is not nitrogenous, and contains of carbon 42·8 per cent., hydrogen 5·8, oxygen 51·4 per cent.

It differs from animal gelatine in being but slightly prone to undergo change, and other seaweeds mixed with a little of this and made into jelly, sweetened and flavoured ready for use, have long been imported from distant Singapore, and will keep for years. It was first imported into France from China about 1856.

Importer.—M. E. Holdsworth, 3 Norfolk Street, Bradford.

Japanese Chillies.—These seem to correspond with orange-red form of capsicum annuum, var. *conoides.*

Japanese Pepper.—The fruit of the *Xanthoxylum piperitum*, which is esteemed as a condiment in China and Japan, the fruit capsules being agreeably pungent and aromatic when bruised.

Japanese Plums, or Medlars.—See *Loquats*.

Japanese Rice.—The annual crop is from 180 to 200 million bushels, and England imports between five and six hundred thousand piculs a year (133⅓lbs. equals one picul), which is about twice as much as any other country takes.

It is most extensively raised in the valleys of Nippon. The harvest is in November, and the new rice reaches England from February to May.

Japan nets a large profit annually by exporting native rice of superior quality and importing nearly as much of inferior foreign sorts at about half the price from Corea, East Indies, and China.

Japanese Soy.—See *Soy*.

Japanese Teas.—(See also *Teas* and "*Tea of Heaven.*")—Tea is not indigenous to Japan, but is thought to have been introduced there from China about the eighth century. It has only been cultivated in Japan about five hundred years, and it was not until about 1857 that the Chinese method of curing was adopted. The tea grown in Japan is generally of an inferior quality, possessing only an infinitesimal quantity of that comforting but volatile property known as theine. A considerable quantity of green is now prepared, and much of it goes to the United States.

America has always been the largest consumer, and of some 40,000,000lbs. exported yearly from Japan, 30,000,000 goes to the United States and three parts of the remainder to Canada. It should, however, be remembered that no impure or adulterated tea is now allowed to be exported. Every package is inspected by the Japanese Government, who are thus successfully raising the reputation of the article, and severely punishing all offenders.

Japan teas may be roughly divided into three classes: Yokohama leaf, Kobe leaf, and Nagasakis; but the latter forms only a very small part of the whole.

The chief district in the Yokohama teas is the Hacheoji district. These teas are of very fine quality, and little or none of them ever reach this market, being practically all shipped to the United States and Canada. They are of small leaf, very similar to Kobe teas. The balance of the Yokohama leaf teas are generally of flat leaf. The finest teas from all Japan come from the Hacheoji district.

The chief district in Kobe teas is the Yamashiro district. Kobe teas, as a class, are of better style than Yokohama teas, but the latter are, on the other hand, superior in cup quality, grade for grade.

Nagasaki teas are of very indifferent cup quality, dark liquor, and usually highly fired. Teas from this district are generally curly in the dry leaf, and about half the crop is made into Japan Gunpowders.

In Japan teas, as a whole, the earlier the leaf is picked in the season, the better the quality, and the early pickings are paler and more flavoury in the liquor than second-crop teas. Second-crop teas have darker liquor, and are also thicker and have more body in the cup. They are usually of better style, the firers being able to produce better style from the second crop.

Amongst Japan teas may sometimes be found a spurious leaf, usually called "cabbage," not discernible in the dry leaf, but giving a rank and offensive flavour to the liquor whenever it occurs. This so-called "cabbage" is really the leaf of a convolvulus, which climbs over and about the tea plants, and occasionally a leaf of it is accidentally picked and cured with the tea leaves proper. It occurs more frequently in some districts than in others.

The preparation of Japans differs

from that practised in China, in so far that the Japanese farmers pick the leaf and only partially fire it, packing it in large china vases, in which it is brought down and sold, in its half-fired state, to the large tea-firing and shipping houses at the coast, where the firing is completed by the European, American, and Japanese shippers in their own premises, with Japanese labour.

The Japanese generally reduce the tea leaves to powder before brewing with boiling water, and this plan is sometimes adopted in China.

It is stated that the best results are obtained when the powdered tea is infused for about five minutes in moderately hard water the moment it comes to the boil. The flavour is then exquisite, the theine is completely extracted, and very little tannin, whilst no loss of body or strength is perceptible.

The *Yushin Nippo*, in a recent article on the necessity of cleanliness in the manufacture of foods, draws attention to the dirty habits of the men and women employed in the tea-firing godowns. The class employed is generally poor and badly clothed, and the adoption of strict measures of cleanliness may lead to a decrease in their numbers, with the compensating advantage, however, of an advance in wages to those that remain. Anyone who witnesses, continues the *Yushin*, the filthy ragged people, the women with dirty babies on their backs, going in to the tea-firing godowns, must surely feel some disgust, and if such a state of affairs is allowed to continue it will certainly have a bad effect on the tea trade of Japan.

Japan packages average about 65lbs. each.

Japanese Waxes.—(See also *Vegetable Wax.*) — Japan wax—sometimes called Sumach wax—is obtained from the tree *Rhus vernicifera*, or *R. succedanea*, which is found in China, Japan, and throughout the East Indies generally.

Japan wax has only been on foreign markets for about thirty-five years, but has rapidly become an important article of trade. It is extracted from at least four plants—*Rhus succedanea*, *R. vernicifera*, *R. sylvestris*, and *Ligistrum ibota*.

The trunks of the second of these species, called *Wrushi* in Japanese, furnish the famous Japanese lacquer, and, as it cannot be made to furnish that as well as wax, it is usual to call upon it only to supply lacquer, which it alone can do, and to rely upon the three other species for wax. *R. sylvestris* (*yamahaze*) and *Ligistrum* (*ibota*) are common enough, but they are not made much use of, as their yield of wax is small. Practically, then, *R. succedanea* is depended upon for wax almost entirely. It is principally cultivated in the islands of Kiousiou and Thikshou, in the centre of Nippon, and it grows well both on plain and mountain, and especially in sandy, gravelly soils. The young plants are raised from seed, and become productive at the age of seven years, giving at first from 7 to 15lbs. of fruit per foot in height, but later from 55 to 80, and sometimes even as much as 200lbs. At the age of forty the yield of the tree begins to lessen, and it is cut down at about a yard from the ground and the stump is grafted. The flowers appear in April and the fruits ripen in November. The fruits yield about 2 per cent. of their weight in wax. The fruits are never treated for the extraction of the wax until the April following the harvest. The wax improves as the fruit gets older. They are first thrashed and winnowed, to free them from stalks. They are then ground to the finest possible flour, with repeated sifting and regrinding of the coarser particles till everything passes through the sifter. To get the best wax the seeds must be removed from the fruits before they are ground. To extract the wax the flour is steamed on a hempen cloth stretched over boiling water, and then compressed in a special apparatus. This consists in the main of a metal cylinder

with square wooden rods arranged vertically round its internal surface, and having a hole in its bottom for the wax to run out at. The flour is placed inside the rods in a hempen bag, and then the pressure is applied. The oil cake can be broken up and again pressed, but the second lot of wax is inferior to that first squeezed out. The second residue forms an engrais, or is burnt to furnish the lye required for the bleaching process. The wax is bleached by melting the dark yellow raw product, and adding to it one-fifteenth part of its weight of water. After decantation a lye is added, and the molten wax is poured in a thin stream into cold water. It is then dried in the sun on screens. There it is stirred every day with a rake, and completely turned over twice a week. It is sometimes necessary to sprinkle the screens with water to prevent the solar heat from melting the wax. After two or three weeks the wax is ready for the second fusion (*nakain*), which only differs from the first (*aodashi*) in the fact that no lye is used. At the end of two or three weeks more the wax is fused for the third time, after a last insolation, and cast into rectangular moulds and allowed to cool very slowly. At that stage it is sometimes mixed with a little oil to make it less brittle. It is now ready for the market.

In making candles of this wax, which the Japanese still do in spite of the necessity for snuffing them constantly and of their evil smell, the crude wax is almost exclusively used; but as European candles replace these native ones the Japan wax will be more and more largely exported. A large number of foreign middlemen already exist, but the Japanese are forming syndicates to export directly themselves. It is difficult to obtain reliable statistics as to what the production of this wax used to be in Japan. In 1876 it probably did not exceed 4,000 tons, but in 1887 reliable figures give it as 11,000 tons, about half of which came from the department of Fukuoka. As to the value of the exportation, it has fluctuated fairly regularly, up to 1891 between £40,000 and £60,000. It is now much more. It takes place principally to Hong Kong, the English having secured the middleman's place.

It has often been found adulterated with starchy materials to the extent of 20 to 25 per cent.; but this adulterated compound is free from the peculiar network of minute cracks which as a rule characterise the surface of the pure wax, and has a higher specific gravity.

Its preparation is one of the principal industries of Kinsin, the best coming from the province of Hizan.

A white wax, secreted by the insects *Ericeris-pela*, is also obtained in Japan. (See *Chinese White Wax*.)

Kaga wax is obtained from *Cinnamomum pedunculatum*, and is softer than ordinary Japan wax, but is not exported.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Jardinieres.—A French name for small bunches of vegetables and herbs made up by greengrocers from young turnips, carrots, spring onions, French beans, leeks, etc., etc., all fresh, clean, and tender, ready for use in making soups, broths, garnishes, etc.

Jatropha Manihot.—One of the names for the plant from which Cassava meal is obtained. The juice also furnishes Cassava starch and tapioca. (See *Mandioca*.)

Java Coffee. — An East Indian variety of coffee, cultivated under the Dutch Trade Association, which is in turn controlled by the Government of Holland, and obliged to ship all that is raised of the first quality to Holland, where it is graded and sold at Amsterdam or Rotterdam by Government auctioneers to the highest bidders, whether German, French, or Swiss, all of which are large consumers and will pay big prices for it.

Europeans are indebted to the Dutch for their first acquaintance with the coffee plant. This was brought about

in the following manner: Some berries which had been procured were carried to the Island of Java and there planted. A specimen plant was sent home to Amsterdam in 1690 by Governor Wilson. This plant bore fruit, from which many young trees were propagated, and from this original most of the gardens of Europe and the East Indies are supposed to have been furnished.

Very little of the best Java coffee comes to England. The quality depends very much upon the districts in which it is grown, as with wines, tobacco, etc., and in a very great degree upon the curing the berry receives, some of the Government qualities being turned and browned in the sun for three or four years before being shipped for market. This treatment gives them age, colour, strength, and richness of flavour, which qualities give this brand of coffee its peculiar character and value.

The Dutch Government allows about 25/- per picul (133⅓lbs.) to the natives for cultivating the coffee, and the natives generally do this in lieu of paying taxes.

Java coffee berries are of a large oblong form, varying in colour from whitish to pale yellow and greenish. It is considered a very fine species, producing a strong and clean liquor, and second only to genuine Mochá.

Java Sugar. — Annual production about 600,000 tons. There are about 190 manufactories, viz.:—
106 in East Java, making 350,000 tons.
53 in Central Java, making 180,000 tons.
30 in West Java, making 70,000 tons.
The area occupied by the sugar cane culture is about 70,000 hectares.

Java Tea. — The cultivation of tea in Java was begun in 1826 from Japanese seeds and plants; but Indian seed and the Indian method now prevail, and the business is increasing rapidly, especially in the Preanger district. The trees are never allowed to exceed 2½ feet in height, but they are very prolific, an acre yielding about double as much as in India. They are grown 3,000 to 4,000 feet above sea level. Java teas yield a substantial liquor, and the taste of some of them is attracting the attention of many dealers. The export in 1898 was about 70,000 chests, and the average price about 6d. per lb. Much of it is really sold as genuine Assam. The finer kinds are often marked "Japan Pekoe" and the lower kinds as "Japan Congou."

Jellies. — F. *Jelées;* G. *Klare Sulzen;* Port. *Gelêas;* Sp. *Jaleas.*

This term is generally applied to substances, either vegetable or animal, which are liquid or semi-liquid while warm, and become stiff or gelatinous on cooling. There are so many kinds of jellies that they have been divided into several headings, and will be found under *Aspic, Black Currant, Calf's Foot, Fruit, Guava, Red Currant,* and *Table Jellies.* All vegetable jellies have pectine as their base, while animal jellies have gelatine.

A few years ago nurses, and even doctors, thought that jelly was the most strengthening of foods, but other opinions now prevail, and jellies (though still prized as valuable articles of food) have had to abate many pretensions. (See *Gelatine.*)

"*Jelly Squares.*"—The base for these is in many cases tengusa seaweed. The seaweed is carefully washed and boiled to a gluey decoction, which is strained off and put into square boxes. When cool it forms a stiff jelly, which can easily be divided into squares a foot in length. The manner in which the surplus water is removed is very ingenious. The jelly prisms are exposed in the open air during a cold night and allowed to freeze; during the day the sun melts the water, which runs off, leaving behind what one might term the skeleton of white, horny substance, which is extremely light and easily dissolved in hot water. When cold it again forms a stiff jelly.

This article is applied to many purposes—for culinary preparations, for making bonbons and jellies, for clarifying liquids, as a substitute for animal isinglass, for making the moulds used by plaster of Paris workers, etc., etc. With the addition of sugar, colouring matter, and flavouring essence all kinds of jelly squares are thus easily made.

Cheap Jellies are also made as follows:—Take 20lbs. of sugar, 65lbs. of glucose, 12lbs. of starch, and 12 gallons of water; use a sufficient amount of the water to dissolve the starch thinly; add the balance of the water to the sugar and glucose, set it on the fire or in a steam pan. When it arrives at the boiling point add the dissolved starch and about three-fourths of an ounce of tartaric acid, this dissolved in a little water; also add the colours and flavours desired; evaporate to a good body or until the goods will leave the finger in cold water. This will be a stiff jelly, and should be poured out into trays and spread to even thickness, then set aside until cold. Oil the trays well and then sprinkle well with pulverised or granulated sugar before pouring the goods into them. When cold turn the trays upside down on a slab and the goods will drop out; then with a sharp knife cut the batch into squares, diamonds, or sticks, and while moist throw them into granulated sugar, cover them well, then sift them carefully and set away to dry. If you desire to run this same jelly into starch prints, do not evaporate so high.

But the bulk of the jellies made—the article which is bought by the masses—is a fraudulent product, and is a great money-maker for the firms that put it on the market. No matter what kind of jelly is asked for, or what flavour is wanted, it is all made from the same basis, and doctored to suit the requirements. The proportions used in making the general "basis" for all kinds of jellies are as follows:—Glucose, 50 per cent.; sugar, 10 per cent.; and apple juice, 40 per cent. Some acids are used in the manufacture of jellies, but it is not for the purpose of giving tartness to the taste. The only object the acid accomplishes is to make the substance jellify more quickly.

Apply to the Pure Cane Sugar Co. (J. Philip & Co., agents), importers of West Indian Products, 4 Fenchurch Buildings, London, E.C.

And for Materials for jellies.—C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Jeraad.—A food consisting of preserved locusts. In certain parts of the world where these insects frequently abound (as in Morocco) they are collected, filled into sacks, and sold for food, like prawns or shrimps in England. They are first boiled in salt and water, then fried and parched, and in this form are considered "clean" by the native Jews and Mahomedans, and esteemed as a convenient form of food for travellers to take with them on the road.

Jersey Tea.—See *New Jersey Tea.*

Jerked Beef.—Beef cut into thin slices and dried in the sun. (See *Tassajo*, also *Pemmican.*)

Jerupigia.—See *Geropiga.*

Jerusalem Artichokes.—F. *Topinambours*; Ger. *Erdartischocken.* (See also *Artichokes, Chinese Artichokes*, etc.)

These are not really artichokes at all, do not take their name from the city of Jerusalem, nor have they any connection with it, but are simply the tubers of a species of sunflower (*Helianthus tuberosus*), long known in Italy as *Girasole* (turnsole), or turner to the sun. They are often used as a substitute for potatoes, and when cooked have a peculiar sweet watery taste, very like that of genuine artichokes, and hence the name.

The plant—a composite one—is a native of Canada and the upper

Mississippi river, but has become a well-known and prolific garden vegetable in England, although much more extensively grown in Belgium and Holland. In cultivation, the tubers are first planted in rich ground well exposed to the sun, in rows 3 feet apart, and 18 inches apart in the row. When young they contain a considerable amount of phosphoric acid and potassa.

It is a perennial plant, and the stems, which grow to a height of 4 to 6 feet, are, with the leaves, generally used as fodder for cattle.

Cultivators should remember that the white-tubered variety has the nicest shape, is a good cropper, keeps well, and will grow anywhere.

Perhaps the best kind is "Sutton's White," with whiter skin, shallower eyes, and better shape than most of the other varieties.

In some parts of France Jerusalem artichokes have been used for the distillation of alcohol. They contain no starch, so do not become floury on boiling, but yield a soluble substance resembling starch, and known as *Inulin*. They contain a large proportion of sugar, and are cheaper than potatoes. It is to be hoped that the alcohol thus made will be applied to legitimate purposes, such as the manufacture of varnishes, methylated spirits, and transparent soap. In France its distillation is carried on somewhat considerably, the plant being grown very easily, and in places where potatoes would rot. The Cape farmers find them an excellent root-fodder for cows in milk, also for pig-feeding.

Jesuits' Powder.—See *Quinine*.

Jesuits' Tea.—Obtained in Chili from the leguminous plant *Psoralea glandulosa*. (See also *Maté*.)

Jewellers' Cement.—Dissolve over the water bath fifty parts of fish glue in a little strong spirits of wine. Add four parts of gum ammoniac. Separately dissolve two parts of mastic in ten parts of spirits of wine. Mix the two solutions and keep them in well-stoppered bottles. In order to use this it must be warmed over the water bath.

Jewellers' Rouge.—(See also *Toilet Rouge*.) — A scarlet and impalpable polishing powder.

The genuine kinds are prepared from peroxide of iron by heating the yellow oxalate of iron till it decomposes. The carbonic acid escaping, only this fine red powder is left. (See *Red Crocus Powder*.) Jewellers' rouge may be recommended to polish silver or gold ornaments, plate, and specula without injuring them. A very good plate rouge may be made by mixing equal parts of precipitated subcarbonate of iron and prepared chalk.

Occasionally some injurious compounds have been sold under the name of jewellers' rouge.

For materials, apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Jewellers' Sawdust.—This is the sawdust of boxwood, and is used for brightening and drying gold chains, etc., which when placed in it are well shaken, and afterwards brushed. This sawdust is much improved by drying it well in the oven before use.

Jew's Apple.—An American name for the *Egg Apple* or *Egg Plant*. (See latter.)

Joar.—See *Millet Seed*.

Johannisberg, or *Schloss Johannisberg* (as the highest grade is termed), is a rare white "cabinet wine" produced in the environs of a village of that name on the banks of the Rhine, in Germany. It has been famous for centuries.

The grapes are grown in the Rheingau district, under the walls of the old abbey of Johannisberg, the vines yielding this "crême de la crême" actually growing close to and over the cellars where the wine is stored. The much-envied estate belongs to Prince Metternich, and consists of 62 acres, which are cultivated with scrupulous care.

Johnny-Cake, or Tortilla.—(See also *Maize Bread*.)—A simple kind of

bread, very popular in the United States, Central America, and Mexico. It is made by soaking three cups of yellow corn-meal (Indian meal) in four cups of sour milk, or butter-milk, overnight, or for six or eight hours. In the morning add half a teaspoonful of salt, a tablespoonful of brown sugar or good molasses, one egg, and a large teaspoonful of carbonate of soda. Beat the batter well, and it will be quite thin. Pour it into two shallow biscuit pans and bake from half to three-quarters of an hour in a hot oven, and serve at once with butter, treacle, or other savoury food. In Mexico and Central America it is called Tortilla, and often made into sandwiches with meat or a sauce of tomatoes and Chili pepper.

Johore Teas. — The Sultanate of Johore is the only independent Malay kingdom on the peninsula, and the tea grown there, a hybrid Assam, is considered fully equal to any produced either in Ceylon or elsewhere.

'Jonathan."—An adulterant sometimes added to barley meal, Indian meal, etc. It consists of calcined and ground oat-chaff, and whether eaten either by man or animal is very indigestible and liable to irritate the intestines so as to bring on inflammation.

Jordan Almonds. — (See also *Almonds.*)—The most esteemed variety of sweet almonds. They take their name not from the River Jordan, but from a corruption of *jardin*, or garden, to distinguish them from uncultivated almonds, and are grown in the Malaga district of Spain. There are two sorts, one large, flat, and oblong in form, while the other is remarkable for its brittleness. They are more plump, less pointed at one end and less rounded at the other. If split open there will be observed on one edge of the seed, near the narrow end, the remains of the funiculus, or seed-stalk, which extends half way down the seed to the point of attachment to the shell or ovary. Jordan almonds have also thicker and harder shells and somewhat paler skins than other sorts, and are more delicate in flavour. The shells containing the sweet kernels are all cracked by hand, giving employment to large numbers of girls. Imported, without the shell or endocarp, from Malaga in 25lb. boxes.

Jordan almonds appear to be getting smaller in size every year, and this is explained by the British Consul at Malaga to arise from the fact that the medium and lower grades only are now cultivated, the production of *firsts* and *seconds* being almost *nil.*

Jowarree.—See *Millet Seed.*

Jugged Hare. — F. *Lièvre à la Daube.*

This is sold in tins as a breakfast delicacy. The hare is usually cut up into small neat joints, dredged with flour and fried brown. It is afterwards simmered for about two hours with beef gravy, onion, lemon, cloves, pepper, salt, and cayenne. Sometimes small forcemeat balls and a little port wine are added.

Juice.—See *Liquorice Juice.*

Jujubes.—(See also *Gelatine Sweets, Gum Drops,* etc.)—The word jujube has *three* separate meanings. Firstly, it is a name given to several species of plants of the genus *Zizyphus*, which grow in Syria and Southern Europe. Secondly, to the fruit of these plants. A well-known one is that common jujube shrub, *Z. vulgaris*, an olive-shaped fruit about the size of a small plum, red or yellow when ripe, and used as a sweetmeat, and from the juice of the fruit a lozenge is prepared by confectioners. Thirdly, and chiefly, the word jujube is applied to a confection, sweetmeat, or medicated lozenge, round, oblong, or square in shape.

The low-priced are supposed to be made of gluten or gelatine, water, and sugar, and flavoured with various fruit essences or similar mucilage; the *best* from fine gums, such as gum Arabic or gum Senegal, flavoured and sweetened, perfumed, medicated, or otherwise treated with a decoction of the jujube fruit, when they form valuable

remedies, or preventives, for sore throats, chests, etc. They are also used for coughs, fevers, etc.

How to make ordinary quality:—Dissolve 4lbs. good powdered gum (Turkey or East India) in three pints of water, well stirred in a gentle heat, remove scum, and after cooling slightly, strain it through a fine hair sieve. Next boil 4lbs. loaf sugar (with a little cream of tartar) to the "crack," then add the dissolved gum; keep stirring it and let the whole mass evaporate gently to the small pearl, or 30°, by the saccharometer, for half-an-hour, skim again and add the colour, jujube decoction, or flavour required. Then pour ½ inch deep into oiled shallow tins, dry for two days; afterwards cut into long strips and finally into regular squares with scissors or knife.

Special Manufacturers.—J. Epps & Co., Ltd. (glycerine jujubes), 48 Threadneedle Street, London, E.C.

Julienne (pr. *Zhool-yen*).—A celebrated French mixture of dried vegetables and herbs. The name is from that of Mme. Deschamps, a Paris market woman, who died in 1897 at the age of 94. She supplied vegetables to the Tuileries during the reign of Charles X. and Napoleon III., and her mixture of herbs became popularly known as "Julienne." The notion was improved upon by Chollet & Co., in 1848, according to a selection of vegetables and herbs suggested by the renowned *chef* Soyer, Chief Inspector of Cookery to H.M. Forces in the Crimea.

It consists of carrots, turnips, onions, cabbage, parsnips, leeks, lettuce, celery, etc., with a little sorrel and parsley. Sometimes asparagus tops, green peas and French beans are added. The vegetables are cut while fresh into thin strips, not unlike matches, and the lettuce, sorrel, and leaves of chervil into larger pieces. Each kind of vegetable is dried separately, and the whole afterwards mixed together in the proper proportions which constitute the secret of manufacture.

It must be admitted that, notwithstanding the fame of our English gardens, and the keen enterprise of manufacturers, both British and foreign, the appetising fragrance and delicacy of Chollet's French Julienne has never yet been equalled. It is made at Meaux, in France, and still remains pre-eminent in the first hotels and in all aristocratic *cuisines*, owing to its superiority over all imitations.

Messrs. Ch. Prevet & Co., the successors of Chollet & Co., have had for many years past a depôt in London (134 Fenchurch Street, E.C.), and seem determined not only to uphold but to extend the prestige of their well-known brand.

There are some cheaper sorts in the market, but most of them are incongruous mixtures of the commoner and coarser vegetables, which no retailer who values his business should risk sending to a high-class cook.

Julienne is sold, wholesale, in 1lb. packets, in bags of 28lbs., and in sacks of 1 cwt. The sacks are chiefly bought by soup manufacturers, hospitals, workhouses, soup kitchens, and schools, the bags by hotels, restaurants and clubs, but the *1lb. packet*, which bears plain "Directions for Use," is in the form in which the public ask for it from the grocer. It also keeps better in this form, and free from dust or waste.

Julienne is also sold, for export, in a compressed form. (See *Compressed Vegetables.*)

Caution.—Julienne must be kept in a *very dry* place.

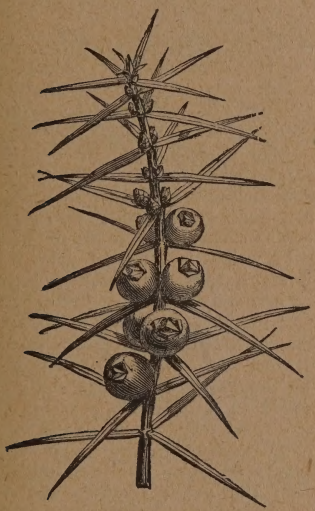
Juniper Berries. — Du. *Genèvre Bessen;* F. *Baies de Genièvre;* Ger. *Wachholder-beeren;* Ind. *Abhul;* It. *Cocole de ginepro;* Sp. *Granos de Enebro;* Sw. *Enbuske.*

The fruit of the low fine-leaved resinous shrub or tree, *Juniperus communis.* It is related to the cypress, and grows wild over many of the hills and heaths throughout Europe.

There are at least a dozen species from which these berries are gathered, but the most remarkable is the above, which is found in many parts of this

country upon dry barren commons or on chalky sandy lands. In cold situations this bushy evergreen may grow 15 to 20 feet high, but seldom attains more than 3 to 6.

The berries require two years to grow and ripen, are of dark purple colour, about the size of currants, and contain three small stones.



JUNIPER.

Considerable quantities of juniper berries are imported from France, Italy, Holland, and Germany. They have a strong, but not disagreeable, smell, and warm pungent sweet taste. The pungency seems to reside in the skin, the sweet in the juice, the bitter in the seeds, and the oil in the pulp. Juniper berries should be chosen fresh, round in form, and not much shrivelled, also free from mould. Prices, 7/- to 10/- per cwt.

Juniper Oil. — A volatile essential oil, very subtle and pungent, distilled with water from juniper berries, also from the tender tops or *shoots* of the plant itself, but this must not be confounded with *Cade Oil*, made from juniper *wood*. Oil of juniper wood is commonly prepared by distilling turpentine over juniper wood.

Juniper oil is composed of terpenes and a solid camphor-like body.

The berries for distillation are gathered while green, but full grown.

The unripe berries probably yield the most oil, but this oil is very inferior to that obtained from the ripe fruit.

The oil is of a pale greenish colour, and a warm aromatic taste, with a strong flavour of turpentine, and, in fact, juniper oil is often adulterated with the latter.

When the oil is freshly distilled, it will dissolve in four times its volume of 95 per cent. alcohol, but when a few weeks old it is less soluble.

An evaporated cold infusion of juniper berries is sold by the druggists under the name of *German treacle*. The principal use made of juniper oil is in manufacturing or flavouring gin, Hollands or Schiedam.

Junk.—The outer covering of the coco or coker-nut reduced to a mass of threads, a rough kind of oakum, used for caulking the seams of a ship and making mats, etc.

Jur Nuts.— See *Ground Nuts*.

Jute.—Fibre of the jute-plant, largely imported from Bengal, and made into bags, ropes, etc.

K

Kaffir Corn.—See *Millet*.

Kaffir Tea. — An African product obtained from the leaves of *Helichrysum nudiflorum*. It is demulcent, and considered good for pulmonary complaints.

Kaiffa, or Oriental Fecula. — An alimentary preparation used largely throughout the East in making potages. It is usually a mixture of potato flour, sago, saleep, rice-flour, cocoa, sugar, and

either lichens or gelatine. The whole is generally flavoured with vanilla or other aromatic. Different manufacturers have their special brands and names for analagous compounds.

Kail. — See *Cabbages.*

Kaiserlautern Beer.—See *Beers.*

Kaki, or Japanese Date Plum.—This fig-like fruit (*Diospyros costata*), of which there are a great number of varieties, is nearly allied to the persimmon (*Diospyros virginiana*), but much superior.

It is very common both fresh and dried in China, where it is called "Tsze" or "Sze," and is fairly abundant about Florence, in Italy. The word *Kaki* is from *Chaki*, the Japanese name for the fruit. The best known varieties are *Tame*, *Nashi Yemon* (seedless), *Hyakume*, *Yedo*, *Ichi*, and *Kurokumo*, and these are now cultivated extensively in Florida and other parts of America, also in Adelaide. The plant sprouts very freely from the seed, and is afterwards grafted upon the seedlings of the wild persimmon. They are gathered some time before they begin to soften if intended to go distances, but like other fruit they are much better flavoured when fully ripe.

Kalamboki. — A Grecian name for *sorghum*, or Chinese sugar cane. (See *Sorghum.*)

Kalydor.—A fancy name given to several nostrums widely advertised, and pretending to possess extraordinary powers of beautifying the skin. (See *Rowland's.*)

Kapok Oil. — A vegetable fat expressed from the seeds of the *Bombax pendundrun*, a plant belonging to the *Malvaceæ*. It is related to the cotton tree, and the seeds are very similar. It flourishes throughout the East and West Indies, where the oil or fat is used for culinary purposes. Kapok Oil is, however, chiefly used for soap making in this country, and is brought into the European markets by the Dutch.

Kari. — A Continental mixture of ground pepper, pimento, and turmeric, flavoured with clove and cinnamon. This powder is commonly steeped in vinegar and used as a sauce.

Karita, or Karite. — See *Shea Butter.*

Kava Kava, or Yava Pepper. —The root of *Piper methysticum.* (See *Ava.*)

Kauri, or Kourie Gum. — Also known as Dammar, or Australian copal. This is the gum resin which exudes from the *Dammaris australis*, or Kauri pine, the finest and most useful kind of tree found in Australia and New Zealand.

These magnificent trees grow 120 to 180 feet high, and the dull amber gum or resin is often found in lumps of 50 to 100lbs. weight in the ground far from any present trend, but where forests of these large coniferous trees, have formerly grown and died.

Although a true resin, this is usually called *gum.* It is the solidified turpentine of the kauri, and occurs in great abundance in a fossil condition in the northern part of the Auckland Provincial District, from the North Cape to Middle Waikato, and is dug up alike on the driest fernhills and the deepest swamps. The purest samples are found on the Cape Conville Peninsula. A large amount of an inferior quality is also obtained from the forks of living trees. The fossil resin occurs in lumps from the size of a walnut to that of a man's head, but three specimens weighing over 300lbs. have been exhibited.

When scraped the best is of rich brown colour; sometimes it is transparent or mixed with leaves, seeds, or insects enclosed. The dark resin found in swamps is almost black, and only fetches a very low price. The most transparent is the highest priced, and often used instead of amber for the mouthpieces of pipes, cigar holders, etc.

The digger's equipment is a gum

spear or pointed iron rod fixed in a handle to test the ground; the gum is then dug out with a spade, and carried home in a sack. Some dig over an entire area. An old knife is used to scrape the gum, and the scrapings are used in making fire-kindlers. Wages about 27/- a week, living 10/-, savings 17/-.

It is invaluable in varnish making, dressing glazed calicoes, and the great bulk is exported from Auckland for these purposes. Its specific gravity is 1·080, and its melting point about 400° F.

Fifty years ago its value was unknown, and the first cargo (some 800,000lbs.) exported to New Bedford, Mass., in 1849, laid there for three years before 100,000lbs. could be sold at 2½ cents a pound; four more years elapsed before the last 8,000lbs. were sold at 35 cents a pound. In 1860 it only brought £9 a ton, but the price in 1893 had run up to £61 a ton.

When its value was first discovered Kauri was collected by the Maoris, but "whites" now do a large portion of the digging.

Kay's Compound Essence of Linseed.—This medicine was patented in 1873 by Mr. Kay, a Stockport chemist, but three years afterwards the patent lapsed. Under the Act then in force a fee of £50 was necessary, and this was not paid. It therefore is no longer a patent medicine. Each bottle contains about one-seventh of a grain of morphia, and as that is the chief active principle it must only be sold by registered chemists.

Kazan Soap.—A Russian toilet soap, made largely from the less pure and very yellow qualities of egg oil. This soap is very high priced, and is only used by the wealthy classes as a luxury. It is regarded chiefly in the light of a cosmetic, and is a much valued addition to a Russian lady's toilet necessaries.

Keating's Cough Lozenges.—These are said to consist of lactucarium, 2 dr.; ipecacuanha, 1dr.; squills, ¾ dr.; extract of liquorice, 2 ozs.; and sugar, 6 ozs.; made into a mass with mucilage of tragacanth, and divided into 20-grain lozenges.

Keg, or Cag. — F. *Fût, Caque;* Port. and Sp. *Barica.*

A general name for any small cask, dry or wet, holding less than 10 or 12 gallons.

A keg of spirits means abou 5 gallons.

Kei Apples, or *Dingaan Apricots.*—The berries of *Aberia Caffra,* imported from Africa. In their fresh state they are very acid and often used alone as pickles, but when preserved with sugar form a most agreeable jam.

Kelp. — Ashes of seaweed, or, in other words, a collection of marine plants, cut from the rocks off Ireland and Scotland, with a hook, gathered and dried on the beach, and afterwards put into kilns, where they are melted by the heat. They are then agitated with iron rakes, and, when cooled, condensed into a dark blue or greenish mass, hard and compact. It yields about 5 per cent. of its weight of soda, and used to be very valuable, but is little used for that purpose now.

Kerosene, or Astral Oil. — An American name for petroleum which has been extra-refined for illuminating purposes.—This name is also the popular one in India, China, Japan, and other regions where the hydrocarbon kind of oil has been introduced for domestic uses. The best should be almost colourless, and its flashing point 149° F.

Kerosene, also, is highly recommended as a hair restorer, preventing it falling off and often renewing the growth over bare patches.

In certain districts of China—Chefoo, for instance—the farmers in sowing seeds allow a few drops of kerosene to fall on the seed as it lies in the drill to protect it against insects apt to feed on the seed or tender plants.

Ketchup or **Catsup** (from the Japanese word *kitjap*).—Names gene-

rally applied, in conjunction with the fruit or vegetable substance forming their base, to a variety of sauces or condiments.

When an article is merely labelled or described as "Ketchup" or "Catsup," without fuller definition, it may ordinarily be considered to be made up artificially, and should be carefully tested.

The kinds usually sold are:—Camp, cucumber, marine, mushroom, oyster, pontac, tomato, walnut, wine, etc. Most of them are described under their respective titles.

Apply to Charles Cocks & Co., Reading, Berks.

Kid Revivers. —The following is an outline of their manufacture:—

Dissolve 9lbs. of Marseilles soap in a gallon of water, then add 1½ gallons of a clear solution of chloride of lime and a pound of sal ammoniac. Mix thoroughly.

Kiel Butter.—Kiel is a fortified seaport town in Schleswig-Holstein, Prussia, and situated on a fine bay of the Baltic, about 53 miles N.N.E. of Hamburg.

It has long been celebrated as an export centre for superior butters, but the term "Kiel" butter has gradually been widened till it seems to include any or all butters shipped on the North Sea and the Baltic, especially Hamburg factory butters. Indeed, it is also often applied to Irish or other sorts, which are merely sold in those peculiar sort of casks called "kiels" or "keels." Hence we have "kiels of butter" as well as "kiel butters." The word has now really lost its value as a descriptive title.

Importer.—R. Rutherford, 112 Whitechapel, Liverpool.

Kieselguhr, Diatomite, etc. — Kieselgühr, from *Kiesel* (silica or flint) and *guhr* (fermentation), is the German name for an infusorial earth, very light and porous, found in several parts of the world, but the largest quantity at Naterleuss, between Hamburg and Hanover. At Bilin, in Bohemia, there is a bed of it 14 feet thick; another at Richmond, U.S.A., 30 feet thick. Vast beds also occur at the bottom of the South Pacific. Similar deposits, known as *diatomite*, are found near Aberdeen in Scotland, South Mourne in North Wales, also at Randan in France, where it is called *Randanite*, and in Norway, where it is called *Bergmehl*. Its porous structure makes it look as if it had been "raised" by yeast, like bread. It consists entirely of the silicious skeletons of very small plants called diatoms, many of which are too small to be perceived by the naked eye. The deposit at Naterleuss reaches from the surface to a depth of 150 feet, and is in three distinct parts. The best Kieselgühr is found on the top mixed with sand and a little organic matter, which are separated by levigation. The middle layer is grey, with less of sand and more of organic matter, but the lowest and main deposit is of greenish colour, and varies from 50 to 100 feet in thickness. These are burnt in furnaces like peat, and raked out at the bottom. It assumes a ruddy brown colour, interspersed with atoms of white silica. Kieselgühr, being thus purified, has many uses. Being an excellent non-conductor of heat, and incombustible, it is used for stuffing the linings of fireproof safes, wine cellars, ice boxes, and refrigerators; also as a packing for boilers, steam-pipes, and retorts, filters for water, and sugar refining. It has been found to be a good absorbent of carbolic acid, and is consequently largely used in the manufacture of disinfecting powders.

Much is also used in the manufacture of dynamite, water-glass, metal polishes, and numerous other purposes.

Sold wholesale by C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Kilo. — An abbreviation of the French word *Kilogramme*, equal to 2lbs. 3 ozs. English; 50 kilos equals 110lbs.; 12½ gallons water, wine, vinegar, etc., weigh about 50 kilos.

Kino. —An astringent extract in the form of shining grains of a deep brownish red colour, obtained from various Australian and Indian trees. It really consists of tannin and other extractives, and in India is used for dyeing cotton a nankeen colour; also employed in medicine.

Kippered Herrings. —F. *Harengs Saurés.* (See also *Herrings.*)

A name for herrings which are first split and flattened out like finnon haddocks, and then slightly salted, dried, and smoked.

They are sold by the score or dozen in boxes, or else packed in flat tins to retail at about 8d. each.

Kips. —See *Chamois Leathers.*

Kirschbranntwein or **Kirschen.** —German names for *Cherry Brandy*, which see.

Kirsch or **Kirschenwasser.**— F. *Kirsche.*

A sort of Cherry Brandy, a thick white spirituous extract, very pure and sparkling, with excellent and wholesome qualities.

It is made at Griesbach and Petersthal, in the Reuch Valley, Strasbourg, and in other parts of Germany, but chiefly in the Black Forest, from small black wild cherries, a kind of Morello cherry, the fruit of the *Prunus avium* (a Machaleb variety).

When the cherries—ripe and unripe, sound and rotten—have been crushed and begun to ferment in a wooden vessel, they are stirred, two or three times daily, for a short period; the stones are also broken and the kernels crushed, and it is from this pulpy mass the famed and powerful spirit called Kirsch is distilled and rectified.

It owes its peculiar flavour to cyanic acid, a poisonous element present in the kernels of most stone fruits; but it is sufficiently diluted with distilled water, and very slightly sweetened with liquid glucose. It has the reputation of assisting digestion, and has the curious property of decomposed fruit when added to it in bottle.

The best qualities contain about 0·15 grm. prussic acid per litre, but inferior makes often contain three or four times as much.

It is a very common and favourite liqueur with the Swiss, and large quantities are made at Montreux, but the principal distilleries in Switzerland are in the cantons that produce the best cherries—viz., Basle, Lucerne, Schwytz, and Zug, where many of the farmers also make it. Both black and red cherries are used, but the former are best. They are first very carefully cleansed and the stems removed, then packed in very thick wooden casks and left to ferment five to eight weeks, according to the weather, after which distillation is effected. The larger distilleries hasten the fermentation by steam, while others employ naked fires of peat or cherry refuse. The Kirschenwasser is marketed in litre (1·76 pints) bottles, in carboys of 10 to 60 litres, and in casks, and the wholesale prices vary, according to the cherry season, from 1/6 to 3/- per litre, but is generally adulterated with 5 to 75 per cent. of German potato spirit, and is exported largely to America, India, and France.

Factitious kirschwassers are also made in France of dilute alcohol, sweetened and flavoured with peach blossoms, cherry-laurel leaves, oil of bitter almonds, or even nitro-benzine, but very fair qualities are made at Fougerolles and in Brittany.

Some sorts are rather hot, but for "cleansing the palate" Kirschwasser, if genuine, is more suitable and more agreeable than *Maraschino*, which is also made from cherries. It improves with age.

Kirsebœr Liqueur. — Danish for the celebrated *Cherry Brandy* manufactured by Peter F. Heering, Copenhagen, established 1818. Purveyor by special appointments to the Imperial Russian and Royal Danish Courts, and to H.R.H. the Prince of Wales.

Sold by the leading wine merchants. Original cases of 12 bottles or 24 half bottles.

Kissmisses.—A variety of small grapes grown in Persia, from which the *Shiraz Wine* is made. Large quantities also are dried and sent to India.

Kitchen Fee. — A cheap cooking fat of hard and waxy appearance, made of the fat and grease from the kitchen, with 20 to 30 per cent. of cottonseed oil added in order to soften it and make it spoon or cut like butter or lard. It is cheaper than dripping, and largely used by the lower classes in large towns.

Kittool Sugar.—See *Palm Sugars, Toddy*, etc.

Knife Polish.—A powder for cleaning table-knives, fire-irons, and all kinds of bright steel goods.

A good one may be made by grinding furnace clinkers or slag to a fine powder, but a small disintegrating machine will be almost indispensable.

Knots.—A sort of crystallised fruit. The fruits are cut into long strips and then, while pliable, tied into the shape of knots. They are afterwards crystallised in ordinary way. Knots are made in different colours, and are sold either separate or assorted. Used chiefly for decorating cakes, etc., but also esteemed as a dessert fruit.

Kohl.— The German name for cabbage.

Kohl-Rabi (said to be a corruption of *caulorapa*).—A singular variety of cabbage (*Brassica caulo-rapa*), in which the base of the stem is enlarged into a green turnip-like mass, bearing the sheathing bases of the leaves. The plant is now considered by De Candolle to be a variety of *B. Campestris*. Both sheep and cattle are very fond of it.

Koker Nuts.—See *Coker Nuts*.

Kokwyn. —An African wine resembling Malaga. Made in Cape Colony from muscat grapes.

Kokum Butter.—A substance obtained from the seeds of *Garcinia indica*. It mainly consists of stearin, and is often used to adulterate *Ghee*.

Kola, Kolla, or **Colah Nuts.**—F. *Noix de Kola*; G. *Kolanüsse*; It. *Noci de Kola*; Sp. *Nueces de Kola*.

Also known in the Western Soudan as *Guru* or *Gourou Nuts* and in Congo as *Makasso*. These are the brown bitter seeds of a native West African tree, which resembles a chestnut tree, and grows 30 to 60 feet high, and is identified as *Cola* or *Sterculia acuminata*.

The pods grow in clusters of 10 or 12 together, each pod 4 to 6 inches long, containing 5 to 15 nuts or seeds, somewhat resembling chestnuts, of both red and white colours. The nuts are collected by females, then shelled and examined with great care, and some are reduced to powder before export.

The great centres in Africa of the kola nut trade are in Goree and Gambia. The tree grows freely everywhere in the tropics, thrives wherever planted, but prefers low moist lands near sea level. It yields its first crop at five years and is in full bearing in ten years, yielding some 120lbs. seed annually. The flowering is continuous. In Western Africa the nuts for transplanting are each packed within wet leaves. The Germans are growing large quantities in Togoland.

Fresh kolas are greatly fancied by the natives for their bitter flavour and tonic properties. They are also commonly used in a powdered state to purify stagnant water that has become muddy and putrid. In the Soudan the natives chew the nut, suck the juice, and spit out the fibrous matter. It enables them temporarily to withstand the pangs of hunger, thirst, fatigue, sleep, and other exhaustion. Mr. C. F. Scott Elliott, in his report on the botany of Sierra Leone, says half a kola nut will enable a man to go without food and do hard work for 24 hours or more. It is also said to counteract quickly the effects of intoxication.

Stanley, in several of his works on Africa, mentions kola as possessing

much greater sustaining power than either tea, coffee, or cocoa; the natives, he says, carry the beans in their pockets, and eat them during long marches.

The leaves also are reputed to possess similar qualities, and these are used both fresh and reduced to powder. Powdered kola certainly has a very disagreeable earthy flavour, but to cover this it is generally mixed with cocoa, coffee, or wine, although the earthy flavour may to some extent be dissipated by boiling for five minutes.

During the last twenty years the kola plant has attracted considerable attention in Europe, and in view of its probably becoming an important article a number of plants were propagated at Kew in 1880 and distributed to Calcutta, Ceylon, Demerara, Dominica, Sydney, Mauritius, Zanzibar, Java, Singapore, and Toronto, so that at the present time the nuts are produced in other countries than Western Africa. Jamaica supplies a considerable quantity.

Unfortunately, the supposed virtues both of the nut and the leaves are, in a great measure, lost in drying for exportation, so that their value in this country is very doubtful, and medical men are now averse to their use except in drugs.

The virtues of tea, coffee, cocoa, tobacco, and some other products are enhanced by drying or roasting, but this is very uncertain as regards kola. However, the prices charged for kola preparations in England are exorbitant, and altogether beyond their value as food adjuncts.

Some of the dry and rotten-looking nuts and leaves which are put on the market are quite worthless, and impart no value to the foods or beverages made up with them.

On the Liverpool and London produce markets the nuts themselves sell at 2d. to 5d. per lb. Spurious kola nuts have been met with in the English markets, particularly "Mora Nuts," often 7 to 8 inches long and 3 broad, one seed nearly filling the pod, and the seeds of *Dimorphanda mora*, a leguminous tree of British Guiana and a division of Cæsalpiniœ; but these false kolas are only used in the West Indies for feeding cattle, and have really nothing to do with the kola, neither do they contain caffeine.

Kola Cafe or Kolatina.— An extract of *kola-nut*, coffee, and chicory. It may also be prepared as follows:— Take one teaspoonful of kola powder for each cupful of water used, mix the powder evenly with a little cold water, and then add the remainder of the water, hot or cold. Boil this for five or six minutes in an open pan, and finally pour into a jug or pot, allow it to settle for a few minutes, and use as required. The addition of a little fresh roasted coffee gives it a suitable flavour.

Kola Tea. — An African beverage prepared by infusing the fruit or seeds of the kola tree. An analysis made by Professor Attfield shows it to bear a close resemblance in composition to ordinary tea and coffee, except in containing much starchy matter.

The following fluid extract has been recommended:—2 drs. of the fluid extract of kola, with a half drachm of sal volatile, and flavoured with saccharine elixir.

It undoubtedly wards off the pangs of hunger, enables a person to walk a long time without food, and increases the power of resisting fatigue from any prolonged labour, but the after effects are bad.

"Komo" Black Enamel, for grates, etc.—A quick-drying enamel, for imparting a rich and lasting glossy black surface to stoves, fire-irons, grates, and any kind of wood or iron-work, bicycles, etc.

It is much superior to Brunswick or Japan black, and is sold in 2d., 4d., and 6d. tins (self-opening).

Sole Manufacturers.—Paton, Calvert, & Co., Leeds Street, Liverpool.

Korarima (also spelt *Kurarima*).— The fruit of the *Amomum augusti-*

folium, a larger variety of Abyssinian cardamum. It seems to have the flavour of both the ordinary cardamum and the caraway.

Kosher or **Cosher Food.**— This is the marked food or meat of any kind which has been killed or prepared by the Jews after their own manner, according to the Talmudic ordinances as to the knife to be used, its shape, etc., and for the consumption of the members of that community.

In the Talmud "Kosher" means pure, clean, lawful; and *Trep*, *Trifa*, or *Traifeh*, unlawful or unclean.

People are often puzzled at seeing small parcels containing a few pounds of fresh meat going by passenger train to small seaside stations "to be left till called for," considering that at the meanest resort there is always a shop where good meat can be obtained, and, if somewhat dear, it would still be less than the cost in town, plus carriage charges. The explanation, however, is very simple. The parcels are from Jewish butchers, there being no local butcher of that faith. The very orthodox take with them saucepans, plates, dishes, etc., and so obtain the meats in the only way by which both letter and spirit of their law can be obeyed.

Koskossoo or **Couscoussou.**— A dry food of coarse meal, or semolina, prepared from sorghum and various cereals, and mixed with fish, flesh, or fowl.

It seems to form the national dish of the Arabs in North Africa, Senegal, Gambia, Guinea, etc., who invariably offer it to important guests. It was a great treat to partake of "Couscous" at the "Arabian Village" in the Paris Exhibition (1889).

In times of famine the tubers of *Arum arisarum*, called "*irene*" in Morocco, are dug up, washed, sun-dried, and ground between handmill-stones; the meal is then cooked by steam, like Koskossoo.

Koumiss (sometimes spelt *Kumiss*, *Kumyss*, etc.).—There are three or four kinds of Koumiss, made by the Tartars, Kalmucks, and other tribes of Northern Asia.

1. The chief is a vinous and intoxicating liquor consisting of mare's milk beaten up and fermented, nearly like clear butter milk. It is very sour, but free from grease.

2. A strong spirit which is distilled from the above by the Kirghis and other nomads. This sort is also called *Rack*, or *Racky*. About 6 ozs. are distilled from 20lbs. of milk, but the flavour is not pleasant.

3. Other kinds of Koumiss are made from the milk of camels, asses, cows, etc., and all are considered good for sufferers from consumption.

The real Koumiss from mare's milk is a really valuable remedy, and this kind of caseine seems to lie on the irritable stomach when nothing else will.

Ten parts of the fresh warm milk, with a little sugar, are added to one part of sour milk, and the whole is allowed to rest for two or three hours, with repeated stirrings.

The chemical results are a partial decomposition of the sugar into lactic acid, the development of carbon dioxide and alcohol, and the partial changing of the albuminoids into peptones.

It is very difficult to prepare properly, and is extremely liable to vary, either from the yeast often employed in fermenting it, or from the temperature. Doctors say it is best when about six days old. Special hospitals have lately been opened in Russia for treating consumption cases exclusively with Koumiss.

An artificial dry sort is made from ordinary milk, cocoa-butter, bi-carbonate of soda, citric acid, etc., in the form of tablets, from which, by solution in water, an effervescent Koumiss beverage is produced.

Leban in Arabia, and *Yaoust* in Turkey, are similar fermented drinks made from milk. *Galazyne* is an imitation Koumiss prepared from cow's milk.

Kovno Honey.—A celebrated kind of honey produced in the great *linden* or lime-tree forests near Kovno, in

Lithuania. It is much valued for its medicinal properties, and for making liqueurs.

Kumerah or **Kumari.**—See *Sweet Potatoes.*

Kummel or **Doppel Cummel.**—A sweet cordial or liqueur, chiefly made at Riga and in the Baltic Provinces of Russia, by distilling cummin, fennel, and caraway seeds in spirit—the strong flavour of caraway overpowering the others. It is the favourite liqueur of Russia, and very popular in Germany, also in Java and throughout the Eastern Archipelago. It has a pleasant, stimulating taste. The best quality is known as *Allasch*, and made at Weissenstein, in Esthonia, and is of the kind known as "Crystallised," the crystals forming at the bottom of the bottle from excess of sugar. Another class is known as non-crystallisable. Imitations of Kummel are also made in France by all the liqueur distillers.

Inferior sorts are made, both at Riga and elsewhere, with weakened spirits (usually brandy), and flavoured with coriander, caraways, etc.

Kumquats.—See *Cumquats.*

Kuromoji Perfume.—A new essential oil, obtained from the young shoots and leaves of the plant *Lindera sericea*, a Laurineous shrub growing 4 to 6 feet high in the mountainous districts of Japan.

The wood of the tree is much used for making toothpicks, and the oil, which has a pleasant, aromatic, balsamic odour, is becoming very popular in perfumery, especially for soap-making.

This oil is not produced on a large scale by any extensive distillers, but by small farmers in Japan, each of whom distils the yield from his own shrubs. These small stocks are then bought up by dealers in various centres and mixed together, hence it is rather difficult to find two parcels of the oil alike in odour.

L

Labels, Plain or **Coloured.**—Many articles are more or less sold by the label attached to the box, package, or bottle in which they are presented to the public eye. John E. Southall, Colour Printer, Dock Street, Newport, Mon., has had many years' experience in the preparation of commercial labels and wrappers, and issues specimen sheets (coloured), containing some of the patterns he is prepared to execute. Don't put up with an inferior article for the sake of saving a few shillings and perhaps losing pounds, but write to J. E. Southall, as above. Cost of sketches allowed on order being given. Labels suitable for grocers, confectioners, bottlers, drysalters, chemists, etc.

Labels and Paste.—See *Paste.*

Labrador Tea.—A common name given to the narcotic leaves of the *Ledum palustre*, a kind of Erica which are collected in North America, and used in brewing or rectifying ales and spirits.

Lac.—The lacs commonly sold are known as *Button Lac*, *Gum Lac*, *Lac Dye*, *Lump Lac*, *Seed Lac*, *Shellac*, *Short Lac*, *Stick Lac*, *White Shellac*, *French Varnish*, etc.

The lacs are produced in Asia by the insects *Tachardia lacca;* but in the South-Western States of America by the congeneric species *Tachardia larreæ* (Comstock).

Shellac, used largely in hat manufacture, also in preparing varnish, etc., is the purified resin obtained from *gum lac*, a resinous exudation caused by the puncture of an insect, the female *Coccus lacca*, which thus deposits its eggs upon the branches of certain kinds of trees in several hot countries, particularly in the jungles of Central and North-Western India, known as *bibar trees*, *pepel trees*, etc.

Twice a year (in March and October) the resinous substance forms as a crust, often half an inch thick, upon the twigs, and these, cut into lengths of two or three inches, are called *stick lac*. *Lump*

lac is the same thing formed into cakes.

The *stick lac* is carefully watched on the tree, and at the exact period when it is clearest and freest from colour it is gathered, then broken into small pieces about the size of rice, winnowed to free it from seeds, pieces of bark, etc., and is now called *seed-lac*.

It is next freed from colouring matter by washing in water and lime; and this colouring matter, when pressed into cakes, becomes the *lac dye* of commerce; but lac dyes have recently been almost wholly superseded by coal-tar dyes.

The gum is now dried and sifted, and put into long sausage-shaped cloth bags, heated over a fire, and the gum strained at will—either in the form of *shellac*, *button-lac*, or *short lac*.

The centre of lac production in India is about Chota Nagpore, Rewah, Mirzapore, and Assam. The well-known brand "D. C." is a product of the pioneer European factory in India, originated by one David Campbell, now carried on by Kardine Skinner & Co., and is of the highest quality. The "T. N." brand is made by anybody, and is of varying quality, a committee of brokers fixing the standard every year in London.

Shellac makes the most economical and best drying varnish known. It dries on the surface of the work without sinking in, while its tenacity to the under surface is extraordinary, and at the same time it presents a special affinity for the oil varnish usually placed over it. The most valuable is that of a bright orange colour.

White Shellac—dissolved in alcohol, with sometimes a little gum sandaric added—is well known under the name of *French Varnish*.

The chief adulterants are rosin and fusel oil.

Lachryma Christi. — F. *Larme de Christ;* Port. and Sp. *Lagrima de Christo.*

The name of a highly perfumed and expensive Naples wine, produced from red or white muscat grapes grown at Mount Somma, an extinct volcano, on a slope of Mount Vesuvius.

The skin of these grapes is so thin that the juice exudes in large drops like tears, hence the name. The annual yield is only about 100 hectolitres, and the white wine is preferred, but both red and white are extensively counterfeited by other wines of inferior quality, such as the wines of Pouzzoles, Nola, Istria, etc.

Lacquer. — A varnish composed of seed lac, shellac, or other lac resin, dissolved in alcohol, and used (with a little turpentine and sometimes colouring matter) for coating and protecting from rust various articles of polished brass, iron, or tin—such as chandeliers, gas fittings, and ornamental instruments—which are required to retain their brilliancy without daily rubbing. It is applied with a brush while the metal is warm, or it will not spread evenly.

Lacquers are known as red lacquers, black lacquers, brass lacquers, etc.

The Japanese, who first learnt the art from the Chinese, now excel all others in the manufacture of their lacquer-ware, the finest being made in Tokio and Kioto, while the cheaper kinds are manufactured in the interior. The lacquer is the product of the tree *Rhus vernicifera*, which flourishes throughout the main island of Japan, the lacquer exuding from horizontal cuts made in the bark.

Lactose. — See *Sugar of Milk.*

Ladled Butter. — Ladle-packed butter is professedly genuine butter, washed and salted in different small dairies, and then collected by dealers for the butter merchants, who mix it and beat it together in ladlefuls, so as to produce a larger quantity of uniform quality.

Sometimes this is made up in a very slovenly manner. Inferior and damaged butters, bad as they can be, from Nebraska, Dakota, and other new States, found unsaleable in their original condition, are dumped into all sorts of packages, flour barrels, starch boxes, shoe boxes, soap boxes, or anything that will not leak, so as to be a nuisance, and sent to factories in Minnesota and Iowa, where they are washed, re-worked, and salted, so as to appear in merchantable

form when they are put on other markets, such as Chicago. There the best are sold as "Imitation Creamery," and the other as "Ladled goods."

Lafite or **Chateau Lafite.** — A renowned Bordeaux wine, considered one of the best of red wines.

It is produced in the Medoc district from small black grapes, which look like over-ripe black currants.

Lager Beer (literally, Store Beer). —A light and but slenderly intoxicating German product largely brewed about Berlin, Munich, Dortmund, and especially at Furth, in Bavaria. It is also now largely made in the United States on the system of the "*Pfaudler Vacuum Fermentation* (or F.F.) *Company*," of New York, and there are also a few breweries in the U.K. (Wrexham, Burton-on-Trent, etc.)

The best is made from water, barley, malt, hops, and yeast only.

It is fermented in a different way to English ale, the yeast being added to the beer after the latter has been put in cask, and the fermentation taking place slowly while stored in a cool cellar. It is rich in dextrine and carbonic acid, and, owing to the small quantity of hops used, contains less of their narcotic principles.

Light, brilliant, and sparkling beers are produced in many districts of Germany from various materials.

In East Prussia the moderate local barley is used, but in most districts only the best barley malt, though usually with the addition of raw rice or cane sugar.

All these beers are "*lager*" beers, and the leading principles underlying their preparation are: Short time of boiling both the mash and the wort, and protracted fermentation at low temperatures. It is also found advantageous to harden the mashing water with gypsum. In using maize there is great danger of producing a raw taste, unless the grain be carefully de-germed. Thin barley and a very slightly grown barley are also used; these raw grains being conveniently added in the mash copper.

Bavarian Beer.—The superiority of this beer is attributed to the Bavarian waters with which it is brewed.

Almost every one in Bavaria is a good judge of beer, and the brewer who used poor materials would soon lose his business. The laws also are very stringent against adulteration. Hence only pure malt, superior hops, yeast, and water are used in Munich; but in Wurtemburg the German gets more for his money, rice, maize, maize meal, caramel, chicory, syrups, starch, sugar malt, and raw sugar being largely used.

Brewing Systems.—For simplicity in operation, smooth working, easy control, and perfect cleanliness, no other process can be compared to the Pfaudler vacuum, or F.F. system. By this system the principal and secondary fermentations are combined and completed in one operation, and the beer comes direct from the machine, matured, perfected, aged, and ready for the market.

There are many notable features in the system. Not the least important of these is the collection and storage of the gas made during fermentation, which may be used again as a natural agent for recharging the beer. Another thing worthy of note is that the wort is cooled only to 7½ Reaumur, and the whole process from the beginning of fermentation to the completion of the brew is carried on in closed vessels. The fermentation vats or tanks, of which there are forty, each of 90 barrel capacity—are glass enamelled internally, and can always with the greatest ease be kept spotlessly clean. Once the liquor enters these tanks no hand ever touches it till the process is complete; even the atmosphere does not come in contact with it; only sterilised air under absolute control is allowed to enter during fermentation, which fact, owing to the vacuum and the continuous removal of carbonic acid gas as it is generated, causes an incessant and, of course, beneficial rousing of the beer. The fermentation is finished in about seven days under the Pfaudler system, while on the old lines it used to take three months. Even when vacuum beer is finished on

chips, and is chip casked the same as other beer, the average time from kettle to market is only 21 or 23 days. Another important feature is the arrangement by which only filtered air is used, and the fermentation rooms kept cool and at an uniform temperature all the year round.

Munich stands at the head of the Bavarian beer production, export and consumption. The brewers there produce about 100 million gallons a year, and only obtain 2·1 hectolitres of brown beer from each hectolitre of malt; the consumption of beer in that city is about 130 gallons per head per annum, while in London it is only about 56, Berlin 52, Vienna 65, Paris 3.

White beer is also brewed 2 to 3 million gallons a year; but it is only drunk by the lower classes, Memmingen being its chief centre of production.

The imported lager beers sold in England often contain more or less of salicylic acid, which is added to help to keep the beer longer, but the use of this acid in articles of food or drink is prohibited in France and Germany as injurious to the human system.

Being a very fine and delicate beer, lager is considerably spoilt by travel, changes of temperature, Customs sampling, etc., and is at its best when consumed fresh drawn in the vicinity of the brewery in an almost freezing state.

In Germany carbonic acid gas is used for raising the beer from the cellars to the taps. It seems that the gas exerts pressure on the top of the beer, and forces it upwards through a syphon. Thus the beer does not come in contact with the air at all, and as its own carbonic gas is preserved it is drawn in a fresh condition, and never becomes flat or stale. It is reckoned that over 200,000 German restaurants use compressed carbonic acid gas for this purpose.

Laichees or Le Pilsener Lagers are a light coloured class brewed from the Bohemian hops of Austria, while Bavarian lagers are made from the darker growths of Bavaria.

They rarely contain over 2 per cent. of alcohol, and are scarcely bitter, but have a fine aroma and a special flavour derived from the resinous substance used to caulk the casks.

The offensive taste of pitch (resulting from undue storage in export casks) and the highly objectionable *garlicky* flavour noticeable in some inferior importations, are professedly admired by some persons, but it is only by those who have a limited knowledge of what genuine Lager or Pilsener beers ought to be.

Lagrimas.—A Spanish word, signifying the richest and finest of the sweet wines of Malaga—the droppings from the grapes. (See *Lachryma Christi.*)

Lampblack.— Da. *Könrög;* Du. *Zwartzel;* F. *Noir de Fumée;* G. *Kienruss;* It. *Nero-fumo;* Sp. *Negro de Humo;* Sw. *Kinrök.*

This fine black pigment used to be made from the smoke of lamps, hence its name, but now from the soot or carbon arising from the slow burning of resin, coal tar, pitch, petroleum, tar, etc. A large quantity comes from Sweden, where it is thus reduced from the refuse of resin-making. The above materials, burnt slowly, throw off a dense black smoke, and a fine gauze or a coarse woollen cloth being fixed in the chimney, the lampblack forms a thick coating which is removed from time to time, and packed in casks for use in house paint, blacking, leather work, and other common purposes.

By heating this kind of soot to redness, in an iron furnace, finer quality results. This and another superior sort made from coal-tar are used for making oil pigments, or, along with boiled linseed oil, for making printers' ink. It is also used in Indian ink, carbonic paper, etc. In America lampblack is mostly made from the imperfect combustion of natural gas. Its quality depends on its lightness and good colour. The best lampblack is that procured from burning the wood of the pine and other resinous trees; the in-

ferior kind is the heavy black prepared from bones, and called Bone-black.

Lamps, Oils, Wicks, and Glasses.—Candles have been generally superseded by lamps, and some variety of petroleum oil is usually burnt in them, though the primitive lamp at one time in use consisted of a bowl of rancid olive oil, the wick being kept afloat by passing through a cork or some other buoyant substance. Colza oil is still used in many districts, but paraffin is by far the most popular. The quality of lamp used is very important to everyone burning oil, and no conscientious tradesman will assist in the distribution of lamps which he knows to be dangerous. Cheapness is a great temptation to poor and thoughtless people to choose faulty lamps or those badly made from inferior materials. These are always the lowest priced, but the wicks and the burners seldom fit properly, the screw does not act firmly on the nozzle, and the other fittings are soon loose or out of order. Thus they are often used until a terrible disaster occurs. The glass reservoir is often of very thin glass, and the flame is so near to the oil that the latter is apt to become quite hot and burst the reservoir. An ill-constructed burner or an ill-fitting wick is a constant source of danger by allowing oil to escape every time it is moved or upset. People need to be told that a well-made lamp is always the cheapest; not only is it by far the safest, but it gives the best light, looks well, and will last longer than many of the rubbishy sort. The oil reservoir should be of metal, and not of china, glass, or other fragile material. It should have no other opening than the one into which the burner is screwed. Every lamp also requires frequent attention in trimming the wick, and keeping it perfectly clean. All oil and charred wick should be wiped off before lighting. When new wick requires buying, the purchaser should take the burner to the shopkeeper, so as to get the correct size. The wick should be soft, and not tightly plaited, and should fill the wick-holder without having to be squeezed into it. Most people know that the wick should be well dried by the fire before soaking it in the oil, but an additional means of preventing a lamp from smoking, and of ensuring a brilliant light, is to soak the wick two or three hours in vinegar, and then dry it well before using. When first lit, the wick should be turned down a little, to be slowly raised afterwards. Wicks in carriage lamps or lanterns that are not in daily use are apt to attract moisture from the atmosphere, and should often be trimmed in this way. The proper way to extinguish an ordinary lamp is to turn the wick down until there is only a small flickering flame, and a puff of breath should then be sent *across the top* of the chimney, but *not down it*. An obliging tradesman will occasionally advise his customers on these points, also on how to prevent lamp chimneys from breaking so often. He may tell them to place the lamp chimney in a pot filled with cold water, and add a little cooking salt; allow it to boil well, then cool slowly. Chimneys become very durable by this process, which may be extended to crockery, stoneware, porcelain, china, etc. The process is simply one of annealing, and the slower the process, especially of cooling, the more effectual will be the work. If the glass chimney of a lamp be cut with a diamond on the convex side it will never crack, as the incision affords room for the expansion afforded by the heat. Another essential thing to be observed is to obtain good oil, and here is a hint in economy which the retailer may also give to his customers. Make a strong solution of either alum and water or salt and water, and if the lamp will hold a pint, use half a pint of paraffin and half a pint of one of the above solutions; it will be found that the oil will last considerably longer, with little or no smoke, and give a better light. The oil seems clarified by the presence of the other solution. The lamp is safer to use, for, in the event of any ordinary lamp being knocked over, the denser fluid runs along the wick, and will put the lamp out. The alum and water are the most effectual for

this idea; but the light produced by the use of salt and water is preferable. It is necessary to steep the wick in the paraffin before allowing it to come in contact with either of the other solutions. Of course, this is obvious, but still it is necessary to point it out to some people. This will be found to answer in any kind of lamp, either for heating or for light—and if the salt solution is used in a powerful centre draught lamp, it is surprising how much of the water is consumed. In an ordinary lamp holding, say, a pint, a quarter of a pint of oil to three-quarters of a pint of either salt and water or alum and water will use the oil and give a good light to the last drop, so that, it does not matter how short the wick may be, a little water added will bring the oil up to it. At the National Museum in Washington, U.S.A., there is a very interesting collection of lamps of all ages, from the time of the Pompeian and Roman lamps up to this day. Some of them are very curious, as, for instance, the fire-fly lamp from the West Indies, with living fire-flies. The Japanese lanterns, suspended from sticks, are of many types.

Lampreys. — F. *Lamproies;* G. *Neunaugen;* Port. and Sp. *Lamprea.*

The lamprey is an eel-like cartilaginous fish, having a funnel-shaped mouth, surrounded by a circular suctorial lip, by means of which it adheres to stones, boats, timbers, etc., and to the bodies on which it feeds. There are several kinds in both fresh and salt water. They are from one to three feet long, and they are usually caught in traps or baskets.

Lampreys used to be very popular in England, both as a delicacy for pies and for potting. They are a very heavy and indigestible food, and Henry I. is said to have died through eating them too freely.

They still abound in the North Sea, the Baltic, and German rivers, and reach this country packed in jars, with vinegar, spices, and bay leaves, although not much in demand.

In Germany they are caught, fried, packed in layers, pickled with vinegar, and exported in barrels.

Lancashire Cheese. — The peculiarity and distinctive mark of Lancashire, as distinct from Cheshire and Cheddar, is that it is a softer cheese, a particularly good toaster, mellower, and very palatable when ripe.

Salting in the curd has now taken the place of brining and hand salting. The acidity is obtained by reserving each day a given quantity of curd, say one-fourth to one-third, and keeping it one to four or five days, until it becomes acid, which depends much on the temperature. One day suffices in summer, but five or six days may be necessary when the temperature is low. The milk used should never be lower than 68° F.

The variation of temperature is responsible for the differences in cheese made at the same dairy; and the development of the acidity, which should be neither too little nor too much, is the chief cause of success or failure in cheese-making.

A rich kind is made at Leigh, and others of excellent quality in the Fylde district. They are usually of white colour.

Lane's Catarrh Cure. — (See also *Patent Medicines.*)—Merely a solution of carbolic acid in water, one drachm to a pint. (*Hygiene*, 24th November, 1893.)

Langsat, Lansa, or **Lanseh.** — A very delicious Indian berry, the produce of the *Lancium domesticum.* These berries are a very popular sort of fruit in India, very juicy, agreeable, and cooling.

Lanolin or **Wool Fat.** — F. *Huile de Suint;* G. *Wollfet;* Lat. *Adeps Lanæ.*

A peculiar white and inodorous ointment composed of the yolk of wool mixed with water. It is prepared by various patented processes from *wool grease*, or the lye obtained by washing sheep's fleeces in hot water, or by the more modern method of washing wool in soapy water. Over 12,000 tons of this wool grease is recovered yearly in the Yorkshire woollen mills. Lanolin owes its chief value to its power of assimilating a large proportion of water, and is

made the medium of introducing various medicines. Wool fat in its crude state contains very valuable properties, and is applicable to the manufacturing of pomades, machine grease, etc., but has many impurities and an unpleasant odour. It was perfectly well known by the Greeks and Romans under the name of *œsypus*, a word which only disappeared from the medicine and drug lists about 1720. Since that time wool fat has passed under the names of "*Pompadour Cream*," "*Paris Ointment*," etc.

Lao Tea or **Mieng.** — A kind of tea made from the leaves of *Camellia theifera* (the Assam tea plant) by the Laos, who live in the neighbourhood of Chiengunai, Upper Siam. They do not, however, use the leaves for producing infusions, but prepare them for chewing. The leaves are first steamed, then tied up tightly in bundles, and buried in the ground for about a fortnight.

The natives call the product *Mieng*, and it is said to keep good for two years or more, and to have the same effect upon the nerves as that of drinking tea. Its use is considered to be almost indispensable by natives engaged in hard work, such as poling or rowing.

Lard.—Da. *Svineister;* Du. *Reuzel;* F. *Saindoux;* G. *Schmalz;* It. *Sugna di Porco;* Lat. *Axungia*, or *Adeps suillus;* Pol. *Sadlo Swine;* Port. *Manteiga;* Rus. *Swinoe Saloe;* Sp. *Manteca de Puerco;* Sw. *Svinister;* W. *Bloneg.*

Pure lard used to be the inner fat surrounding the kidneys and peritoneum of the pig, after being separated from the flesh and membranes by the process known as "rendering," and finally straining through flannel or a hair sieve. It is white in colour, free from taste and smell, composed of 62 parts of oleine and 38 parts of stearine, its fusing point being 81° F., and the British Pharmacopœia still directs it to be obtained solely from the omemtum or flare (the fat of the abdomen); but nowadays ordinary commercial lard is allowed to consist of the fat from all parts of the animal. *Keg Lard* is a kind which usually consists of the fat of the entire animal, and not merely that which surrounds the kidneys. Consequently, it contains more oleine, and this having a lower melting point than stearine and palmitine, makes such lard very soft.

Lard is easily prepared from fresh fats. In large factories it is done by the aid of steam, but perhaps it may be of more use here to describe how it is done on a smaller scale.

The fat should be new and fresh, and not old and rancid. It is cut up in pieces not exceeding an inch in diameter, and thrown into a boiler or pan which already contains a little melted lard; as the boiler becomes hotter the shredded fat is continuously added until the boiler is full. It requires well stirring all the time to prevent burning, and the fire should be a slow one. When all the fat is melted it is put through a *lard press*, the refuse is separated and the clear lard again gently simmered, but never allowed to boil. A little bicarbonate of soda and pearlash are mixed together in a little hot water, and then carefully stirred into the lard until well mixed and skimmed from time to time. Sometimes a little ultramarine blue in solution is stirred in with the soda and pearlash to improve the colour. Others add about a tablespoonful of saleratus to every 20lbs. of lard.

After thus refining the lard and while it still simmers, a little ground alum, say, half a pound to each cwt., is usually stirred into it very carefully or the hot lard will overflow the boiler. (This alum causes the oil to blend with the more solid constituents of the lard and to set harder.)

The liquid lard is then filled into bladders, tins, buckets, mugs, tubs, kegs, or other vessels, which are afterwards placed in cold water, where the lard quickly stiffens into a uniform marketable consistency. Care is, of course, previously taken to have the packages thoroughly clean and ready, with the tare of each marked on it before it is filled.

The bladders to be used should have been well pickled in salt, cleaned, and

washed inside and out with both hot and cold water.

By pressure at a low temperature two other valuable products are extensively obtained—*Stearine* for candle-making, and *oleine* or lard-oil for lubricating purposes.

The fat from intestines should be rendered or "tried" by itself, as it is liable to develop and impart a rancid flavour after being kept a short time. Lard is used very extensively in cookery, also in the making of some kinds of soaps, salves, ointments, etc. In Spain and Portugal it is used as a substitute for butter. The commonest adulterants of lard are cotton-seed oil and other flavourless cheap fats, salt, potato, lime, flour, and excess of carbonate of soda, but it appears that excess of water is the chief adulterant. The incorporation of two to five per cent. of milk of lime not only improves the colour, but enables the lard to absorb as much as 25 per cent. of water.

Good lard, however, should need no artificial whitening. If properly prepared and rendered, it is quite white, the presence of any colour indicating either imperfect washing or overheating.

When discoloured, it may be improved by digestion with granular animal charcoal and filtration, while warm, through a column of the same substance.

Many of the American "Refined Lard" compounds consist mainly of cotton-seed oil and a kind of oleo-stearine that is, the caul fat of cattle after the expressure of the oleo oil, the latter fluid going for margarine making.

This stearine is easily distinguished by the aid of the microscope.

Neutral Lard.—This is a name given to the more objectionable but lower priced lard compounds, often made from "dead hog grease," *i.e.*, from animals which have died of disease, or been found smothered, or died on the way to the slaughtering houses.

It is not necessary to add anything to British lard to stiffen it, but American pigs being fed chiefly on Indian corn, the fat is very soft and oily, and one may often notice a separation of drops or pools of an oily fluid. This fluid is *Lard Oil* or *Lard oleine.*

The annual production of lard and lard compounds in America has been calculated to amount to not less than 5,000,000 cwts. yearly.

Its preparation is conducted in connection with the great pork curing and packing establishments at Chicago, Cincinnati, St. Louis, etc., the first-named city, "Porcopolis," however, having the honour of turning out as much as all the rest combined.

The following are the various lard products obtained in the United States:

Neutral lard, or *Kettle lard*, almost exclusively used for the manufacture of margarine.

Leaf lard, originally obtained by melting the whole flare with steam, followed by pressure. The flare is now chiefly used for the preparation of neutral lard, which really commands a higher price.

Choice Kettle-rendered lard, obtained from the flare not used up for neutral lard and from the fat from the back of the animal. It is professedly rendered in steam-jacketed open kettles, at a temperature of about 115° F.

Prime steam lard, of all the fatty parts of the animal, such fat being known in the factories as all round fat, or "hog round."

Butcher's lard, melted on an open fire.

Low Quality lard is produced from the whole abdominal viscera or "guts."

"*Off-grade lard*," a lard of lesser value, prepared from all fat.

Dead hog grease, prepared from diseased hogs; "brown grease," from the intestines; and "white grease," from the other parts.

Yellow grease, prepared from the waste of the packing warehouse.

Pig's foot grease, obtained from the glue factories.

"Prime steam lard" is raw lard, of soft, almost oily, consistence, which hardens at low temperatures. It is melted and crystallised at 10° to 15° C. The lard oil thus obtained is used for lighting purposes, and the remaining fat (lard stearine) is mixed with ordinary

steam lard, to give the mixture sufficient firmness. The whole is then put on the market as "refined" lard.

The "refining" process sometimes includes the use of a mixture of pressed tallow and vegetable oil.

Confectioners and other large consumers desiring the most body or stiffness and most good in their pastry, as well as the best value, should select raw lard as imported in tierces or firkins, instead of small packages like pails, tins, or even bladders.

Pure lard is allowed to contain a *little* salt, say, ½ oz. to the pound, but it should never contain more than 1 part of water in 300 of lard.

Lard with Cotton-seed Oil.—Heat the lard with an alcoholic solution of nitrate of silver over a water bath for 10 minutes. When cold, pure lard should, as already stated, be white, but cotton-seed oil gives a brown or black deposit. In fact, this oil reduces the silver to a metallic state, and is the only kind of oil that will do this. All lard made in winter or spring should keep sweet for 3 or 4 months, and twice as long if in bladders; but if made in hot weather, or exposed in transit, it will only keep sound about a month.

Stoneware jars are excellent receptacles for lard that is to be kept a long time, and a dry cellar or a cool room the best for storage, but a damp and mouldy cellar is to be avoided.

Waterford lard ranks highest of Irish brands, and Belfast comes next.

Flare, *Flick*, or *Leaf Lard* is considered the purest and best, and should consist of the fat immediately surrounding the kidneys. As above stated, it is harder and less fusible, the melting point ranging between 40° and 50° C., while that of the inferior quality, obtained from the fat of the entire animal is about 33° C. Leaf lard also fetches a higher price than the ordinary commercial "first quality" of wholesale quotations.

A rough ordinary test for such adulterants is to melt the lard in a test-tube, when the melted fat will be more or less opaque if any foreign substance has been added. If the lard is pure the melted fat will form a perfectly clear liquid. The simplest way to detect water is to keep the sample in a melted condition for a time, when the water gradually settles out, and if a *graduated* tube be used the percentage can be easily determined, or it may be pretty closely estimated by noticing the loss of weight on evaporation.

Considerable discredit was, however, cast on expert evidence regarding lard adulteration by the exposure of Mr. Stock's analytical errors in the memorable *Kilvert's lard* cases.

Special Firms. — Hillier's Bacon Curing Co., Ltd., Newmarket, near Stroud; Hugon & Co., Ltd.—works: Florin Street, Pendleton, Manchester; George Wall & Co., Ltd., Liverpool and Manchester (see advt., page 10); Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Lard Cheese.—Same as American Imitation Cheese. (See *Filled Cheese.*)

Lard Oil or **Tri-olein.**—F. *Huile de saindoux.*

Obtained by placing lard in woollen bags between wicker-work and the cold plates of hydraulic presses, where it is left for some 18 hours under a pressure of about 10 cwts. to the square inch, in the cold. The oil or *tri-olein* is thus obtained in a pure, colourless, and limpid state and in the proportion of about 62 per cent. of the weight of the lard; but it is so grossly adulterated that it is next to impossible to obtain any in the open market. "Lard Oil" is used as a lubricant and sometimes for illuminating. A little is used in making some kinds of soaps. It is also used in France for adulterating olive oil, and in America for adulterating sperm oil.

Apply to C. Windschuegl & Co., 1 Leadenhall Street, London, E.C.

Lard Soap.—A very hard and high-class variety, of brilliant whiteness, made from, say, two parts of keg lard to one part of soda. It is usually made by the "cold process," that is to say, the high degree of heat necessary in

ordinary soaps is dispensed with. It is generally made inodorous, but if scented the desired perfume is of course added while the soap is in a pasty state.

Lardine Oil.—A lubricating oil for heavy machinery. It is prepared from cotton-seed oil, thickened by exposure to the atmosphere.

Larks (Tinned). — F. *Pâté d'Alouettes.*

These so-called delicacies are mostly prepared in France, where the pretty songsters are cruelly slaughtered in thousands for depraved appetites of the idle classes. Pithiviers, near Orleans, is a great centre for this morbid industry.

Last.—Da., Du., Ger., Sw. *Last;* F. *Lest;* W. *Llwyth.*

A load, hence a certain weight or measure. It is generally estimated at 4,000lbs., but varies considerably. A *last* of codfish, white herrings, meal, or ashes is 12 barrels; a *last* of corn is 10 quarters, or 80 bushels; of gunpowder, 24 barrels; of red herrings, 20 cads; of hides, 12 dozens; of leather, 20 dickers; of pitch and tar, 14 barrels; of wool, 12 sacks; of flax or feathers, 1,700lbs.

Latakia Tobacco (pr. *Latta-kee'-ah*). —One of the most expensive tobaccos sold. Known to botanists as *Nicotiana rustica*, like the Chinese tobacco. It is grown in Northern Syria, Latakia (the ancient Laodicea) being the name of a seaport and district in the neighbourhood of Tripoli. It is a smaller growing plant than the ordinary tobacco, *Nicotiana tabacum*, also more hardy, grows quicker and ripens earlier. It is really the same plant that produces East Indian Manila and Turkey tobaccos.

The different varieties of Latakia placed on the market are the *Abou-Richa*, or *Djebeli*, which is the finest quality, and is only obtained in the high plantations of the Nocaïris, and which is much in favour in Europe as well as in Egypt.

The Djidar is a little rougher in quality, but burns well, and is much appreciated by great smokers.

The *Schick el Bent* very closely resembles the *Djebeli*, with which it is frequently mixed by dealers.

One kind of Latakia has an admired aroma which it derives from being cured in the smoke of oak-wood, and is said to be free from nicotine. The Latakia plant is also now grown in Jamaica.

Latour Wine or **Chateau Latour.** —An excellent red Bordeaux variety, one of the best grown in the Medoc district. The cropped and stunted bushes, attached to low espaliers about two feet from the ground, are generally disappointing to the traveller through this district, who expects luxuriant scenery; and the insignificant and unpromising small black grapes from which the celebrated wines are made resemble very much the large black currants in our English gardens.

Laudanum.—F. *Laudanum.*

The popular name for *Tincture of Opium*, and the usual form in which this powerful drug is used in England.

The preparations of laudanum vary very much in strength, and extreme caution should be used with them. The only opium permitted to be used by the British Pharmacopœia is that obtained from Asia Minor, and is generally known as Smyrna opium, although it does not all come from there. This kind of opium contains about 10 per cent. of morphia, and the tincture of opium, or laudanum, is simply obtained by macerating 1½ oz. of opium in a pint of proof spirit. The strength of the product should be ·754 per cent.

Laundry Blue. — (See also *Smalts* and *Ultramarine Blue.*)—Laundry blue usually consists of starch coloured with Parisian blue. Its manufacture is very simple. A paste is made of, say, 20lbs. each of potato starch and the residue from the manufacture of wheat starch (both perfectly white), 40lbs. of Parisian blue (in the form of paste), 2lbs. of indigo carmine, and 2lbs. of gum arabic (dissolved in water). Sufficient water is added, and the whole kneaded into paste, free from lumps. It is next put into wooden frames and moved into a heated room

till half dry, and then cut into pieces of equal size by a small machine, after which the pieces are completely dried. A polished finish and improved appearance is added by giving them a few turns in a revolving drum, along with a little (say, 1½ oz. to each 30lbs.) finely powdered Parisian blue.

Many are made of common qualities of ultramarine blue mixed with some inert material, such as sulphate of barium, kaolin, and carbonate of soda, the whole being made into a paste and finely ground.

A blue which matches the leading makes of square blue may be made of 40lbs. of ultramarine at about £30 a ton, 20lbs. of ultramarine at about £20 a ton, 4lbs. of carbonate of soda at £7 a ton, and 12lbs. of glucose at £9 a ton. This brings the cost of the mixture to about 15s. per cwt. The plant necessary is a pair of edge runners for grinding the material, and a hydraulic press which will make 63 squares at a time. It has to go through many operations, mixing the raw materials, burning in ovens, chipping and cleaning the raw blue, washing, grinding it in water to the necessary degree of fineness, dividing it by gravitation, drying, sifting, and packing; but the whole cost of material, manufacture, packing, paper, and boxes need not exceed 20s. per cwt.

For good blue, apply to Barringer & Co., Ltd., Rock Valley Mills, Mansfield, Notts.

Laurel Oil, Leaves, etc. — This oil is obtained from the olive-like fruit of the laurel of Apollo (*Laurus nobilis*), a most useful shrub cultivated extensively in Cyprus, and particularly in the southern range of the mountains of that island. The wood, leaves, and fruit of the plant are all valuable.

The leaves serve as a seasoning for cooked or preserved meats and fish, for which purpose they are dried and sold in the markets, also exported. They are also in veterinary surgery considered to be an excellent remedy against various cattle parasites, the parts of the animals most attacked by flies and other parasites being repeatedly washed with a decoction of the same.

The fruit resembles small olives, and when pressed yields a greenish oil as thick as butter, and exhaling a strong, pleasant odour. The oil is used in pharmacy and in perfumery, and both oil and leaves have the property of driving away insects.

Lavender Oil. — F. *Essence de Lavandelol*; W. *Olew Lafant.*

An aromatic and delightful essential oil of pale yellow colour, obtained by distilling in water the newly-opened pale lilac flowers of lavender, also from the flower stems.

LAVENDER.

Various kinds of lavender grow wild on hills and arid mountains throughout Europe, but the best is the cultivated, *Lavendula vera.* The plant is a native of Persia, the Canaries, Barbary, and the South of Europe, from the last of which it is said to have been first brought to England, where, finding a congenial soil, and being cultivated, it yields an oil or otto very far superior to that produced from its original place of growth. Large quantities of this are grown in the Aisne, and especially at Cussy-le-Château, in France. It is also grown in great perfection around Mitcham, in Surrey, and Hitchin, in Herts. The leading growers in the latter district are Quakers. Thirty-five hundred plants

can be grown on an acre of ground if the plants are set three feet apart, and four feet between the rows. An acre of plants yields about 50lbs. of otto of lavender. About 70lbs. of flowers are required to produce 1lb. of oil. The principal constituent of oil of lavender is an unsaturated fatty alcohol called *Lavendol*, in conjunction with small quantities of limonene and a sesquiterpene. The English make is decidedly the best.

The cheap greenish varieties known as "spike" lavender, or *Oil of Spike*, obtained from the flowers of *Lavendula spica* and *L. Storchas*, are sometimes sold as substitutes for the genuine, and at only about half the price, but they are considerably less fragrant, and are chiefly used in china-painting.

Some 4,000 kilos of the oil are made yearly in the South of France, but this is often adulterated with cheaper ethereal oils, such as oil of turpentine and "spike" oil, the prices varying from 1/6 for that obtained from "spike" to 6/- per lb. for that obtained from the finest flowers, according to strength and purity.

Lavender Oil, besides being largely used in perfumery, is employed in the manufacture of lakes and in the painting of porcelain. It is also occasionally used as a stimulant or tonic. Dose 2 to 6 drops.

Lavender Water.—This favourite and very useful perfume is generally made from the essential oil of lavender, rectified spirits, and rose water or ambergris. It is, however, often met with very poor and weak in quality.

Hitchin and Mitcham have for years divided honours in producing England's supply of lavender water, the surroundings and sub-soil of chalk being peculiarly favourable to the plant's growth.

A fair quality is produced by mixing 1 oz. English oil of lavender, ½ oz. essence of ambergris, 10 oz. essence of eau de Cologne, and 1 pint of rectified spirit; or, say, 2 parts of oil of lavender, 1 of essence of musk, 2 of distilled water, and 20 of rectified spirit.

Laver is the name given to two native marine plants, called by botanists *Porphyra lacinata* (Pink or Purple Laver) and *Ulva latissima* (Green Laver). Both are seaweeds, and often used as human food.

In season from October to March.

Laver is very common on the rocky coasts of Scotland and in Devonshire. It is generally soaked in two fresh waters, about an hour in each—to get rid of the salt; then stewed in a little hot water, lemon juice, butter, and spices till quite soft and mucilaginous; but sometimes stewed with leeks or onions, and served up hot with pepper or vinegar, like vegetables with meat. Besides the laver above referred to, which is of purple colour, there is the inferior *Green laver* (Ulva latissima), also used by the poor in a similar way. Laver is now commonly used in London as an aciduous sauce with roast mutton, and is also sold preserved in 1lb. tins.

Lax in Oil.—Norwegian term for salmon smoked and tinned in oil.

Layer Raisins.—See *Muscatels*.

Lazagnes or Ribbon Macaroni.—A kind of Italian paste in thin, undulating ribbon form, and made in same way and of same material as ordinary macaroni, vermicelli, nouilles, etc. It has not a large sale.

Leather Perfume.—See *Birch Tar Oil*.

Leban.—See *Koumiss*.

Lecrelet.—A very delicate and high-class sort of pastry made at Bâle (Switzerland), and which has for its base honey perfumed with citron or orange.

Leeks.—F. *Poireaux*; G. *Lauchen, Porreen*; W. *Cenin, Leeksen*.

The leek is a biennial culinary plant of the onion family, but without the globular base of a mature onion. Botanical name, *Allium porrum*.

The edible root of the leek has the tubular form of a young or spring onion, but is thicker. It is also distinguishable from the onion by its flat, open leaves and its milder flavour. The common varieties are the *Musselburgh* and the large *London Leek*, which are by far the

best; the *Scotch*, or *Flag*, which is larger and hardier; and the *Flanders*. The leeks grown in Wales and Scotland are said to be sharper than the English. Its cultivation is made a subject of great attention by gardeners in Scotland, where its large, rich, and tender stems are carefully earthed up and blanched in the same manner as celery.

To prevent the unpleasant taint of the breath after eating leeks they should be extra well boiled.

The leek is the national badge of the Welsh. St. David, the patron saint of Wales, is said to have suggested to the Britons the wearing of leeks in their caps the better to recognise friends from foes in their battles with the Saxons.

The phrase "to eat the leek" means to submit to humiliating treatment from compulsion. (See Shakespeare, *Henry V.*)

Lee's Pills. — (See also *Patent Medicines.*)—These appear to consist chiefly of aloes with a little scammony, gamboge, jalap, calomel, soap, syrup of buckthorn, and gum.

Legumes, Legumen, or **Pulse.**— G. *Gemüse.*

These are terms for pods or fruits, which consist of a two-valved single carpel, and have their seeds attached to the ventral suture, such as peas, beans, lentils, and several other species of leguminous plants.

The word *Légume* is also the botanical name for seed-pod, but the French employ it for all vegetables, carrots, onions, etc., used as human food; also for various fruits, leaves, stems, roots, fresh or preserved, with the exception of cereals.

Leicester Cheese. — Leicester cheeses proper are small and flat, and made by the "sweet" process. They are at first slightly salted, but salt continues to be added externally. They take a long time to mature.

Leisten-wein. — One of the finest wines of the South of Germany, and being invariably reserved for the Royal Bavarian cellar, it can rarely be purchased.

Leken. — A dark and very sweet liquid which exudes from cuts made in the upper part of the date tree in Asiatic Turkey. It is an excellent beverage while fresh, and in about six hours it ferments and transforms into a wine of very agreeable taste.

"Lemco." — A newly registered trade mark, composed of its initial letters, by Liebig's Extract of Meat Co. (See "*Liebig's Extract.*")

Lemons. — Da. *Limoner;* Du. *Limœnen;* F. *Citrons;* Ger. *Limonen;* It. *Limoni;* Pol. and Rus. *Limonii;* Port. *Limoes;* Sp. *Limones;* Sw. *Lemoner;* W. *Afal Melynhir.*

These valuable fruit, of which there are over thirty different varieties, usually grow on small trees, 10 to 15 feet high, the species being distinguished as *Citrus limonum.* They are native of Assyria and Persia, and were first brought by the Moors from India in the thirteenth century. They belong to the same family as the orange, lime, citron, shaddock, etc. Some varieties grow wild, but others are carefully cultivated, and although of Asiatic origin, lemons are now grown in most warm climates, especially in Sicily, Italy, Spain, Portugal, and the South of France. The best known varieties are:— the tree with sour fruit; with sweetish fruit; with very large fruit, called "Imperial" lemons; with pear-shaped fruit; with furrowed fruit; with clustered fruit; with childing fruit; with whitish fruit; with silver-striped leaves; and with double flowers.

The Imperial lemons from the Bermuda Islands are remarkably large and sweet, and their flavour is delicious, but they are not now so often met with in our markets as formerly. Large quantities of excellent lemons are now also grown in California and Florida; but lemon culture is almost exclusively confined to the Mediterranean region, the growth of that fruit in the United States, for instance, not being equal to 10 per cent. of that country's needs.

Sherbettee Nimbo is an Indian term for the sweet lemons grown around Delhi.

The island of Zante abounds in lemons of a very large size, but Sicily

produces an enormous quantity; in fact, this beautiful island is now chiefly devoted to lemon culture, these having superseded oranges. Sicily lemons are divided into two classes—the best lemons, produced from the April and May blooms, and gathered from October and November; and the bastard lemons, small and hard, and produced from the irregular blooms of February, March, June, and July, which may remain on the trees a much longer time than the true lemon, and withstand bad weather and parasites much better.

LEMONS.

The fruit is really produced all the year round, but what is called the first gathering of new fruit takes place in October, and is termed *primofiore* (choice fruit), all lemons under three inches in circumference being left for the November gathering. Experienced pickers can easily gauge the fruit with thumb and second finger. This first crop is the most valuable, and is shipped off for spring or summer use. It is gathered when quite green.

The fruit collected in November is paler in colour and firm to the touch, but quite equal in quality, and is chiefly exported to the United States and Russia. No small or damaged fruit (culls) must be left on the tree this time, so it is collected, cut up, and packed in brine or peeled, the juice pressed out, boiled down, and sold as "agro cotto" in barrels.

It is used for the preparation of essence and juice, and is considered the best sort for these purposes, yielding about 50 per cent. more than that of other months.

One thousand lemons (trade count, 1,040) give about 16 oz. of essence and 35 litres of raw lemon juice, which (after concentration to the normal standard of 64 ounces of citric acid per imperial gallon) is reduced to 3·5 litres. It costs 1/4 to extract the essence of 1,000 lemons, and £4 to make a cask of lemon juice, including fruit, cost of cask, and labour.

Of the November fruit about seven-eighths is good for shipment, and brings the highest price, and only about one-eighth used for essence and juice. Of December fruit three-eighths is used for essence and juice, the yield of essence being less and the juice more than in November.

The November and December crops are the most abundant, and upon them speculators base all their calculations.

January fruit is more inferior, and that of February (which is the last of the season) yields only about one-fourth of fruit fit for export.

The large "Spatafora" lemons, grown around Aci Reale, between Catania and Messina, are yellow in February and March, and bring as high as 25/- per 1,000.

March and April crops are produced from August and September blossomings, and will not stand a long voyage, nor yield essence nor juice; the former, from August blossoms, are designated "biancuzzi," and are of very little value; but valuable crops may be obtained in May also from September blossomings, and the fruit keeps well to the United States.

June and July produce that known as "*verdelli*," hard, sound, and good shippers, and also the "culls" or "bastardi" lemons, which are sent to London,

Liverpool, etc.; and in August and September the crop is both smaller and inferior to the previous months.

The mountain growths bring the highest prices, but, owing to frosts, the crop is not so sure.

Over a million boxes a year are generally exported from Sicily to the United States, but, owing to the severe storms of winter, the available quantity to ship is sometimes far below that of other years, and the inventive genius of the saloon bar-tender in America is then greatly exercised to produce the multifarious drinks required by our Transatlantic cousins without the important condiment referred to. Lemons usually selling at 2 dollars a box are expected to bring 6 dollars, and possibly 8 dollars or 10 dollars. Three lines of steamers are engaged solely in taking this fruit from Palermo or Messina and Catania.

They are wrapped in thin tissue paper, to assist the ripening, and made up at Palermo into cases of 300 to 450 lemons, boxes of four or five layers, and weighing 86½lbs. per box nett. These are classed as 16, 25, 30, 36, 42, etc., according to the number of lemons in each layer.

As already indicated, two-thirds of the whole Italian crop is really grown in the old kingdom of the two Sicilies.

The large *Citron lemon*, or *Ligurian lemon*, is a large oblong fruit, with a thick, warty rind, and is admirable for candying. The smallest lemons are generally the sourest. Lemons ripened on the tree are almost valueless, for they really become too large, thick skinned, and dry, and are apt to rot soon.

The fruit is best for remote shipment when picked perfectly green and quite hard, and placed in boxes of dry sand, where it may remain four or five months to ripen before being sorted and shipped. The peel having thus become hardened, the danger of rotting is reduced to a minimum.

Lemon storing warehouses in Italy are, like all buildings in that country, of stone, with tile roofing, generally without flooring, and well ventilated. They are provided with long, narrow troughs for receiving and picking over the fruit, and with long, low tables for packing and nailing up the boxes. In some cases the growers ship their own produce, but in most cases the shippers are purchasers only.

Lemons, like oranges, keep longer and better when each fruit is wrapped in paper, so as to exclude the air, or any circulation of air around the fruit; but the boxes should be stored on end, and not be packed too closely together, nor in a close, warm room.

They reach England from Lisbon, Malaga, and Messina in large quantities from the end of September to February, in round half-chests, flat chests, boxes, and cases. After February they become rather scarcer and dearer.

About £400,000 worth now come to the United Kingdom yearly.

Lemons are the chief source of citric acid, and are probably one of the most useful fruits in our domestic economy, their cooling, refreshing, and delicious juice being especially valuable as an antidote against sea scurvy and other febrile and inflammatory diseases, also against biliousness and rheumatism.

Grocers who make the sale of green fruit a particular line of their business cannot bring too prominently before their customers the value of lemons. They are as near being a panacea for all ills as anything can be. Chronic sick headaches and biliousness will disappear if their victim will drink as soon as rising, before dressing even, a glass of warm water with the juice of half a lemon and no sugar. Lemon juice and sugar made very thick and acid will cure a cough and hoarseness. It will relieve feverishness and thirst. Lemonade, as a drink in spring and summer, will prevent or cure "that tired feeling." Hot lemonade taken soon enough will break up a cold. Chilblains rubbed with a piece of lemon sprinkled with salt will disappear. Corns will do the same if lemon juice is administered by dropping it on stale bread and binding on them. Lemons used as soap remove roughness from the hands. A lotion

of half glycerine and half lemon juice is a perfect cosmetic for taking off tan and keeping the skin white and smooth.

If the hands be stained there is nothing that will remove the stain better than a lemon or a lemon and salt.

Some people say that lemons rubbed on the roots of the hair will prevent it turning grey and falling off.

When using lemons for any purpose housekeepers would find it an economical plan to grate the yellow rind off, mix it with an equal quantity of sugar, and put it in an empty box with a tight cover. It will be found excellent for flavouring custards, cakes, and anything else where lemon extract is used. It retains the strength of the lemon while cooking, and is much more delicate to the taste than the oil or extract; or a lemon may be kept fresh and juicy for six months by simply placing it on a flat surface and inverting a glass tumbler over it.

Besides the above uses, lemons are largely employed in making lemonade, sauces, perfumes, etc. (See also *Lemon Pickles.*)

When cheap and plentiful they may be bought and kept fresh several weeks by putting them into clean tight jars or casks and covering them with cold water; keep them in a cool place, out of sunlight, changing the water every two or three days; or dry a quantity of fine sand at the fire, and when it is cold again put a layer of it on the bottom of a clean dry box. Wrap each lemon in silky tissue paper, and place them in the sand with the stalk end downwards, and near together but not touching. Cover this bed of lemons with a layer of sand about 2 inches thick, and then more layers of lemons and sand alternately. Lemons should always be handled carefully, for if bruised they will soon rot.

Lemonade. — F. *Limonade;* Port. and Sp. *Limonada;* W. *Diod afalau melynhirion.* (See also "*Temperance Drinks.*")

This was originally a beverage consisting of lemon juice mixed with water and sweetened; but aerated or carbonised water passed into a bottle containing a little syrup of lemon, or citric acid, sweetened and coloured, is now called lemonade. There is no standard.

In Nice an ounce and a half of orange-flower water is usually added to the gallon of lemonade syrup, and gives both more bouquet and a more delicate flavour to the beverage.

1. An excellent lemonade is easily prepared by taking a dozen small lemons, slicing and powdering them with half a pound of white sugar, and then throwing them into a gallon of boiling water to digest till cool.

2. Mix 4 oz. fresh lemon juice, ½ oz. lemon peel cut small, 4 oz. white sugar, with three pints boiling water; cool and strain. These two "still" lemonades are very refreshing.

3. For a concentrated quality, dissolve 15 oz. lump sugar in 8 oz. lemon juice, flavour with tincture of lemon peel. For use, mix in water with or without a little syrup or essence of ginger.

4. Aerated kinds are often made in following proportions:—One pint of water, charged with five times its volume of carbonic acid gas, and flavoured with 2 oz. syrup of lemons.

5. Boil together 1lb. of sugar and 1 quart of water, add the juice of 6 lemons, and more water when required for use.

Small percentages of sulphuric acid have been found in some makes, and occasionally traces of salicylic acid. The former is, of course, far the most injurious to the consumer.

Lemonade Powders or Crystals —These usually consist of a compound of, say, 16 ozs. bicarbonate of soda, 13 ozs. tartaric acid, 30lbs. icing sugar. The ingredients are first well dried separately, then thoroughly mixed together, and about 30 drops essence of lemon with about 5 drops of essence of pineapple added. The whole is then well mixed and passed through a fine sieve. It should be bottled and corked soon as possible, or otherwise packed in air-tight packages.

Special Firms.—Charles Cocks & Co., Reading; John May, 114 Church Street, Croydon. The latter packs them at 2/- per dozen.

Gardner's patent "Rapid" sifter and mixer, freely used for above. Prices from 50/- to £100. Catalogues from Wm. Gardner & Sons, engineers, Gloucester.

Lemonade Syrup.—The basis of this is a mixture of simple syrup 7½ pints and 2 ozs. of citric acid dissolved in 8 ozs. of water. Prepare an essence of lemon by shaking 1 oz. of the finest oil with 4 ozs. of rectified spirit. Allow to stand for a day, shaking occasionally, then separate the spirituous portion. Add 1½ ozs. of this and 1 oz. of tincture of fresh lemon peel to the gallon of syrup. Three to four ozs. of either syrup may go to a syphon. (Oxalic acid is poisonous.)

Lemon Crystals. — See *Fruit Crystals.*

Lemon Essence.—(See also *Lemon Oil.*)—Only a very small part of the essence of lemon coming into commerce is pure. It is greatly made up of 'citral," a technical term applied to the ethereal oil which is present in lemon oil. 1 oz. of citral in 15 ozs. of 95 per cent. alcohol is considered equivalent to 16 ozs. of lemon oil, and a mixture of one part of citral to 15 of lemon oil is said to be twice as strong as lemon oil itself.

Essence of lemon, or extract of lemon, from the retail grocery trade is generally put up in small bottles of ½ oz., 1 oz., or 2 ozs. each, after being specially prepared for culinary purposes.

The preparation merely consists in mixing 1 part of the oil of lemons with 10 to 20 parts of rectified spirit, adding a little light carbonate of magnesia.

After a few hours it is filtered and coloured slightly with tincture of saffron; or it may be made with spirit and lemon peel, and then filtering the product. Either kind will keep clear and bright for a long time.

Inferior flavouring essences of lemon and orange are sometimes made from the damaged and rejected fruit of the warehouses.

Apply to Charles Cocks & Co., Reading.

Lemon-Grass Oil.—An oil of dark yellow colour, is distilled from a sweet-scented East Indian grass (*Andropogon citratus*), first introduced in 1832; largely cultivated both in India and Ceylon. The plant also grows wild. Its leaves are used as a substitute for tea, and considered very good for the stomach. A perfume is also distilled from the leaves, very like to verbena, which it often represents. (See also *citronella.*)

Lemon Juice. —F. *Jus de Citron;* Ger. *Zitronensaft;* It. *Agro* or *Sugo di Limone;* Port. *Agua de Limao;* Sp. *Jugo de Limon.*

The liquor obtained by squeezing the inside pulp of the lemon (not the peel). The small inferior and windstrewn fruit is mostly used for juice making.

Sicily and the West Indies export large quantities. It has generally a slightly turbid yellowish appearance, and a fluid ounce contains from 36 to 40 grains of citric acid, a litle malic acid, sugar, vegetable albumen, and mucus. The two first render it extremely sour to the taste, but it has been found to be a most valuable anti-scorbutic, as well as cooling and grateful.

In Sicily 1,000 small lemons, weighing some 104 kilos, yield about 17 gallons of juice, and this, in its crude muddy state, is there called "*agro cotto.*"

When purified it becomes almost free from turbidity or stringiness, keeps well, has a pleasant acid taste, without bitterness. Six gallons of raw yield about 1 gallon of the concentrated juice.

It is frequently mixed with varying proportions of spirit, to make it keep better; the spirit, however, should never exceed 5 per cent.

It may also be preserved in bottle a long time by covering it with oil so as to exclude the air, and great quantities are exported from Italy and Turkey in this way.

Lemon juice is also now expressed in England, and may be preserved by agitating a prolonged time with finest powdered talcum, filtering, adding sugar, boiling, then filling hot into bottles and sealing while still hot.

Another plan is to mix 3 ozs. salicylic acid in every 40 gallons, and stir till dissolved.

All sea-going ships are compelled to take a fixed supply of lemon-juice to be served out to the men. The scurvy, formerly so fatal in ships making long voyages, is now almost unknown.

The Board of Trade standard is a density of 1·030 (when dealcoholised), and an acidity equal to 30 grains per ounce of citric acid; but the British Pharmacopœia requires a density of 1·039 and 32·5 grains of citric acid per ounce.

Lemon juice is also a very good remedy for rheumatism and the so-called biliousness of spring. In the latter case the juice should be taken before breakfast. It is also, by the addition of bicarbonate of potass, often made into lemonade. The chief adulterants in lemon juice are water, tartaric acid, sulphuric acid, etc. An artificial kind is sometimes made from 2¼ ozs. citric acid, ½ oz. gum, ¾ oz. lemon peel, 2 ozs. lump sugar, and 1 quart boiling water; macerated till cold, and then strained.

Lemon Kali (also known as *Acidulated Kali*).—A powder of tartaric and citric acid, from which to prepare a pleasant effervescing drink. The following illustrate various qualities:—

1. Mix well-dried tartaric acid and bicarbonate of soda, 1 part of each; then add 2 parts of powdered white sugar in which has been well mixed a little essence of lemon, say 30 minims to each pound of sugar.

2. 24lbs. icing sugar, 9lbs. carbonate of soda, 7lbs. tartaric acid, and 3 ozs. essence of lemon.

3. 60lbs. icing sugar, 20lbs. bicarbonate of soda, 10lbs. tartaric acid, and 6 ozs. essence of lemon.

4. 20lbs. powdered loaf sugar, 4½lbs. tartaric acid, 4lbs. carbonate of soda, and 1 oz. essence or oil of lemon.

The materials should be first well dried separately, then thoroughly mixed together, and the essence of lemon then sprinkled over it, and the whole finally passed through a fine sieve. The powder should be immediately filled into dry clean bottles, and kept as closely corked as possible.

A teaspoonful of lemon kali stirred into a glass of cold water is highly refreshing.

"Lemon kali" was originally a trade name adopted by Godfrey & Cooke for their mixture of sugar, carbonate of soda, and lemon flavouring, and this firm held a monopoly in the article for many years. The term "kali" simply means "ashes," and soda ash was called kali before the metallic element of the potash was discovered, and long before the name of kalium was given to that element.

Lemon, Oil of.— (See also *Essential Oils.*)—The essential oil of lemons is a fragrant and aromatic oil obtained from the outer rind or yellow peel of the fresh lemon, and not from the inside juice. It is easily extracted by rasping or scratching the lemon with a sort of brush made of small needles. This sets the oil free, and it may then be collected with a sponge.

In fact, this sponge process is now the one generally adopted in Sicily. The way it is got at Messina is as follows:—One man with a large knife adroitly cuts off the peel of a lemon in three slices, another man takes them and presses the outer sides against a sponge held in the left hand, bending the peel inside out so as to break the oil globules, but not the peel. This sponge is periodically squeezed over a vessel of glazed porcelain or of common

earthenware. This first yield is far from pure, containing, as it does, a small quantity of juice and of mucilage or other organic matters, which, however, slowly subsiding, form a deposit at the bottom of the vessel; the liquid next sinks, and thus the essential oil is left alone floating on the top. The workman is paid in proportion to the amount of essence he succeeds in extracting out of 35 kilograms of rinds, and a man working this way extracts about 1½lbs. of lemon a day.

It costs about 1/4 to extract the essential oil of 1,000 lemons, and a thousand fresh lemons of November gathering, and weighing 250lbs., will yield about 1lb. avoirdupois of oil, besides about 9 gallons of *lemon juice*, which latter, after concentration to its normal standard of 64 ozs. of citric acid per imperial gallon, is usually reduced to 1½ gallons.

To ensure the cells being fully charged with moisture the lemons should be previously washed in a running stream of water, or soaked for about 20 minutes.

The fruit used should be outwardly intact as well as internally healthy and sound, hence those slightly punctured, windstrewn, undersized, etc., are practically valueless.

The finest quality is obtained from the fresh fruit, but in November and December a large quantity of lemons are cut and packed in cases, and these, instead of being all exported at once, are stored in warehouses. Before shipment, however, they are often repacked, and the bad and doubtful lemons are used for cheap oil making. Such oil, of course, even "if pure," never has a fine flavour, but a smell of the wood (*di legno*) may be easily recognised. An inferior quality is also distilled from the dregs or cake remaining after extraction by the sponge process.

The percentage of *Citral* is the true test of quality and value.

Oil of lemon should contain about ½ per cent. of citral, but having a similar composition to that of turpentine, and developing much the same odour, it is very frequently adulterated with turpentine, which latter is specially purified in a peculiar way so as to have very little smell. Tons of turpentine are used in this sophistication, and it is very difficult to determine with certainty when oil of lemon is or is not adulterated with this refined turpentine, because they are both closely related terpines and both have the same specific gravity.

The sense of smell is largely depended upon. In Sicily it is tested as follows:—A sample is poured out into a tumbler and shaken up after placing the hand on the top. Great attention is then paid to the deviation and size of the bubbles and froth, the colour is noted, and one smell is taken with the glass full and another after emptying it. Turpentine will certainly be detected in this way if over 5 per cent. be present. Genuine oil of lemon is a fluid of a beautiful yellow colour, having a specific gravity of 0·8517. When distilled with water till 3-5ths of the oil has come over, it is obtained in a colourless state, and of a specific gravity of 0.847 at 72° F. It has a delicious smell of the fruit, which is greatly injured by distillation. It is soluble in all proportions in anhydrous alcohol, but only 14 parts dissolve in 100 of spirits of wine of 0·837 specific gravity.

Oil of lemon, if kept long in ill-corked bottles, generates a quantity of stear essence, which, when dissolved in alcohol, precipitated by water and evaporated, affords brilliant, colourless, transparent needles. Some acetic acid is also generated in the old oil.

According to Brande, the specific gravity of oil of lemon is 0·8786. This oil does not become concrete till cooled to 4° below 0° F. It forms with muriatic acid, especially when distilled, similar camphorated compounds with oil of turpentine, absorbing no less than 280 volumes of acid gas.

It is usually imported in copper vessels, but if allowed to remain in them for many months is liable to become con-

taminated with this metal. It is also liable to turn rancid from age if kept in a warm place.

This essential oil (often miscalled "*Essence*" of lemon) is also often adulterated with mineral colza, paraffin, resin, and even pitch. If allowed to stand any length of time in bottle a resinous sediment will often be found at the bottom.

Lemon oil is used extensively in fancy pastry, sweets, liqueurs, and summer beverages, and is not only a luxury, but very wholesome. It should be bought fresh as possible, as wanted. It always deteriorates by long keeping.

Special Firms.—Giov. Restuccia & Co., Manufacturers, Messina, Sicily.

Lemon Peel.—(See p. 171; also *Citrons*, etc.)—F. *Zeste de Citron;* Ger. *Limonenschalen*, or *Zitronenschalen*; It. *Scorze di Limone;* Port. *Corteza de Limao;* Sp. *Corteza de Limon.*

As already shown, the rind of lemons after the pulp, etc., has been removed contains a valuable essential oil, warm, aromatic, and rather bitter. The peel is often candied in its fresh state, and sometimes it is dried; in the latter state it preserves and enhances its delicious aroma.

Considerable quantities of lemon peel or "lemon skins" are imported in water, with 10 per cent. of salt, from Sicily and Calabria, but often about three-fourths of the oil or essence has been previously extracted, and it is probable that the remaining fourth is almost destroyed by the brine, so that this brined peel is very inferior, and may easily be recognised by the taste.

In Barbadoes a celebrated liqueur, known as *Eau de Barbade*, is made from lemon peel.

Lemon Pickles.—In Messina the small, inferior, also oversized growths of lemons are used for this purpose, and the process is a very simple one. The lemons are usually slit into halves or quarters and cored, put into a large vessel and immersed in salt water. They are then packed in casks with alternate layers of salt, and finally filled up with salt water, ready for shipment. Each cask contains about 3,400 lemons. In about a week the whole—both lemon and brine—is ready for filling into jars or bottles, with the addition of a little turmeric and a few capsicums, and covered with warm vinegar.

Lemon Rings.—(See also *Biscuits.*)—Ordinarily made in following form:—Take 3lbs. flour; make a bay, add 2¼lbs. sugar, ¾lb. margarine, cream them up; add five eggs, essence of lemon, ¼ pint of milk, mix and cut out with a 1½ inch cutter, finally cut out middle with a smaller cutter, and bake on tins in a sharp oven.

Lemon Squash.—The two following recipes will show the ordinary composition of this class of beverage:—

(1) Soluble essence of lemon, 1¼ oz.; citric acid, 2 ozs.; freshly boiled water, 6 ozs.; and syrup to make 40 fluid ozs. Colour, if desired, with a little saffron.

(2) Lemon juice, 40 fluid ozs.; boil and filter on to powdered sugar 30 ozs.; dissolve, with agitation, and add 1 oz. of soluble essence of lemon.

A special quality is manufactured by Charles Cocks & Co., Reading, Berks.

Lentils.—Arab. *Adis;* F. *Lentilles;* G. *Linsen;* Port. *Lentilhas;* Sp. *Lentejas;* W. *Pysmelyn.*

These are the seeds of the lentil plant, *Lens esculentum*, an annual leguminous plant very similar to that of the tare and field pea—to both of which it is, in fact, closely related. The lentil plant is, however, of a weaker and more straggling nature. It grows some 12 or 18 inches high, and has white and lilac coloured flowers, which are much sought after by the honey bee.

There are three varieties, conveniently known as the Egyptian, the French, and the German. The Egyptian lentil is a small red kind grown extensively throughout both Egypt and Arabia.

Being usually pulled like flax, not cut with the sickle, thrashed on the ground where they grow, and afterwards swept up, these are generally found to be mixed with small stones

and other gritty substances. These Egyptian varieties, although a shade darker, closely resemble very small split peas.

In France, Algeria, and Germany the greenish brown sorts are mostly cultivated, and these, although larger and coarser in appearance, are considered the best and finest flavoured, also being properly harvested before they are quite ripe, and thrashed in barns, also sifted into uniform sizes, they are much cleaner than Egyptian.

LENTIL PLANT.

Another red variety (*Lentille à la Reine*) is a larger, stronger, and coarser seed, cultivated mostly in Provence, and fed to cattle; but the small greenish lentils with brown spots, grown about Auvergne and Puy in volcanic soil, are highly esteemed, and possess the most exquisite flavour.

Large quantities are now grown in South America, particularly in Chili. The Chili growths are very like the French or Alsacian, but not graded so uniformly.

Lentils are a very ancient food, and very popular with the Greeks and Egyptians.

The name is from "Lentus" (slow), and the Romans objected to their use, because they were thought to breed indolency. On the other hand, Pliny recommended them as producing mildness and moderation of temper. They are mentioned in Genesis.

The "red pottage" for which Esau sold his birthright is said to have been made from the red variety.

Lentils, whole, split, or reduced to flour, are stated to be exceedingly nutritious, and richer in nitrogen than any other kind of grain, although much of the natural flavour is lost by decorticating, splitting, or grinding them. Ordinary qualities contain 5·9 per cent. of legumin, and the general percentage of their composition is: Water 12·51, nitrogenous substances 24·81, fat 1·85, carbo-hydrates 54·78, woody fibre 3·58, and ash 2·47.

If mixed with peas in soup they correct the tendency to flatulence; but they may be more freely eaten along with boiled rice, bacon, etc.

They require soaking in water six or twelve hours to soften before cooking.

The leafy stems are used for cattle, but the yield per acre in hay is only about a third of that of tares.

The English climate is supposed to be too moist for lentil growing, but large quantities are imported. In 1890 England imported about 24,000 quarters of Egyptian from Alexandria alone.

Lentil Powders or **Lentil Flour** generally consist of the dressed flour either of one kind of lentils only, or of two or three kinds mixed together. In some preparations barley flour is added. Nevill's seems to be composed of one part of currie powder, with about 64 parts of lentil flour.

The following recipes represent excellent powders:—

1. 20 parts of Arabian lentil flour, mixed with 4 parts of barley flour, and 1 part of salt.

2. 8 parts of pea flour, 8 parts of corn flour, and 1 part of salt.

Leppett or **Letpet Tea.** — See page 153.

Lessives.—French term for washing powders. There are various makes, but

the one best known in this country is the "Lessive Phenix" of Messrs. Redard Brothers. It seems to be a mixture of carbonate and silicate of soda with soap and perhaps small quantities of other bodies, and its manufacture is of some importance. It is intended to replace soda potash or ashes, and even soap, if the manufacturers are to be believed. It is claimed that it is cheaper than soap and quicker to use, and that it does not damage the linen. Numerous certificates attest the value of this product, and, according to researches formerly made by M. Lelong at the Central School of Arts and Manufactures at Paris, fabrics washed with "Lessive Phenix" were stronger than those washed with soda salt. It is necessary, however, to be careful to attend strictly to the directions given, as the methods of use vary somewhat for different tissues. All the lessives do not possess exactly the same composition, and there are some of them in which the silicate of soda is replaced by other products. In no case ought they to contain any caustic soda.

Lettuce.—F. *Laitue;* G. *Lattich;* Port. *Alface;* Sp. *Lechuga;* W. *Gwylath.*

A common genus of edible plants known botanically as *Lactuca sativa.*

There are several kinds, but they are usually divided into two classes, one of which is called *Cos,* or London lettuce. This does not grow in heads, but has leaves more oblong and upright, which are generally tied round to hold them close for blanching. The other class, called cabbage lettuce, has rounder leaves, which spread out near the ground, and then roll up into heads like a cabbage. Lettuce is generally eaten in the earlier stages of its growth, and is considered an excellent diluent of animal food. It is not very nutritive, but is cooling, easily digested, and slightly laxative. It is said to have valuable narcotic virtues, and a lettuce supper is averred to be very conducive to comfortable repose.

After it flowers a bitter taste develops, and a poisonous alkaloid *hyoscyamine,* which has occasionally led to serious and even fatal results when the consumption has been immoderate.

The plant, a hardy annual, is not found wild anywhere, but is extensively cultivated in Europe as a popular esculent, and especially for salads. Mildew often attacks the leaves; it first begins with pale patches and soon causes putrefaction.

Leverets.—See *Hares.*

Leverpostei, or Liver-pate.—A paste prepared in Norway from calf's liver.

Lexias Raisins.—(See also *Raisins.*)—These raisins, known in Spain as "*Pasas de Legia,*" are produced mostly in Valencia and Malaga, and derive their name from a hot liquor or lye in which the bunches are dipped after being cut and dried, and which greatly assists their final dessication. This lye is composed of water, ashes, oil, and a little salt. After being dipped the fruit is again dried in the sun, or, if the weather be bad, in heated chambers, but in this latter event the product is of inferior quality. After being thoroughly dried the raisins are packed in boxes for market, and are commonly used for cooking purposes.

Liberian Coffee.—A West African species, mostly grown in Mesurado, on the river St. Paul. It is a rather coarse kind, with very large black berries, and of the *Peaberry* type, but is cultivated also in Java and the Straits Settlements, as well as in Guatemala, and grows best in the tropical plains.

The plant is remarkably hardy, tree-like, robust, and prolific, and, being well adapted to low altitudes, it is proving a formidable and successful rival to the growths which heretofore have claimed almost exclusive attention. Export in 1895 600,000lbs., but

in 1896 over 3,000,000lbs. When ground and mixed with ordinary mild varieties it yields a strong and cheap, but still *genuine*, ground coffee.

Imported in bags of about 200lbs.

Libi - Dibi.—See *Divi-Divi*.

Lichens (pr. like'-ens or litch'-ens). —(See *Mosses, Seaweeds, Laver*, etc.) —These are the familiar plants, or fungi growing in thin flaccid crusts on rocks, stones, walls, tree barks, etc., but are quite distinct from true moss. Several of these lichens enter largely into commerce; such are Iceland moss, reindeer moss, and other jelly lichens, liver-wort, Orchella weeds, rock-tripe, etc.

This gelatinous substance is largely employed by brewers for fining beers.

Lichis, or Laichees.—See *Lychee Nuts*.

Licorice. — Should be *Liquorice*.

Lie Tea. — (See also *Macao Teas, Exhausted Teas*, etc.)—"So called by the Chinese," writes Dr. Hassall, "because it is a spurious article, and not tea at all. It consists of the dust of tea leaves, sometimes of foreign leaves and sand made up by means of starch or gum into little masses, which are afterwards painted and coloured so as to resemble either black or green gunpowder.

"The skill exhibited in the fabrication of this spurious article is very great, and we have met with at least a dozen varieties of it differing from each other in the size and colouring of the little masses."

A good deal of "*Lie Tea*" is, however, made and used in Hong Kong, chiefly by native shippers to the Straits Settlements and the United States.

It is mixed in the low-class Ponchong tea used by the Chinese in these places.

In Russia a preparation which has long been sold under the name of "*Rogogeski*" consists of spent tea leaves, re-rolled and mixed with a few genuine tea leaves and earth.

Liebfraumilch.—An excellent German wine grown in the vicinity of Worms. It is full-bodied, as is that of Scharlachberg, and is said to profit considerably from the quiescent state of the air afforded by the town wall.

Liebig's Extract of Meat.—(See also *Meat Extracts*, etc.)—An essence of River Plate meat, originally suggested and prepared by the late Baron Liebig, of Munich.

The first lot of 150lbs. was shipped from Monte Video in 1865, but imitations are now produced wherever cattle are cheap enough. They are made by boiling down lean meat, which involves the loss of fat, and as much of the gelatine and albumen as can be taken away, so as to render the preservation of the residuum possible.

The process is as follows:—The meat of the animal after being killed is allowed to cool for 24 hours. It is then placed in round iron rollers (armed inside with points), which, being revolved by steam, reduce the meat to a pulp. The pulp is thrown into a large vat with water, and allowed to steam for an hour, and is then passed into a reservoir (shaped like a trough, with a sieve at the bottom), whence the liquid of the meat oozes into another vat, whence the fat is drawn off. The pure gravy is then put into open vats, supplied with steam pipes and with bellows on the surface, which produce a blast and carry off the steam, thus helping the evaporation and preventing condensation.

Here it remains from six to eight hours, when it is passed into a filtering vat and drawn off in the form of extract of meat; when cool it partially hardens, and is ready for packing in tins for exportation. It is afterwards divided into small pots and tins as required for retail purposes.

Only 2¼lbs. of extract is got out of 100lbs. of solid meat. It consists of fibrine, osmazone, and the hot water extractives of flesh, including the flavouring matters and potash salts.

The uses to which the extract can be put are innumerable. It seems to have become indispensable to hospitals, doctors, nurses, soup kitchens, hotels, armies, explorers, mountaineers, athletes, and even the ordinary household. The chief demand is unquestionably in the kitchen, for enriching and flavouring soups, sauces, and made dishes.

It has special attractions for invalids, who as a rule are very fond of it. It often induces an appetite for nutritious foods when everything else is regarded with aversion.

Since Liebig first made public his discovery there have been many attempts to follow his idea, and then to give the products the name of "Liebig's Extract." In fact, much confusion has been thus occasioned, not only in the minds of the public but in the retail trade. It should, however, be remembered by all that the baron's idea was only perfected at the Liebig Company's Works, of which, indeed, he became the first director. Their product is always of excellent quality, never gritty one day or "stodgy" another, hence it is now generally preferred.

Dr. Justus von Liebig died on April 18th, 1873, but the company has been a wonderful success from the beginning, and the shares are now at about 250 per cent. premium. It has no connection whatever with any other brand, and has recently decided to place upon all its jars a special label marked LEMCO, the initials of Liebig's Extract of Meat Co., and the signature of J. v. Liebig in *blue*.

Liebig's Food.—(See also *Prepared Foods.*)—A typical food for infants and invalids, introduced some years ago as an improvement, by the addition of malt, to the ordinary ingredients. It is said to consist of malt powder, milk, baked wheaten flour, and saline matter.

Lignite (Brown or Bovey Coal).—Lignite is wood decayed in water, only much more decomposed than peat. It may be described as a medium betweeen peat and coal. Every fossil coal more recent than chalk is termed "lignite," but other formations are regarded as true coal.

Lilacs, Candied. — See *Crystallised Fruits.*

Lima Beans.—A popular kind of pulse, the *Phaseolus limensis*, or perennial kidney bean, largely cultivated in the tropics. (See *Butter Beans.*)

The largest grower in the world is Cav. Leopoldo Schiappa, of Pietra Ventura, California.

Limasool or Lamb's Wool.—An old English beverage, so called from *Lamaes abhal*, which in ancient British signifies "the day of the apple fruit," from being drunk on the apple feast in autumn. It was composed of ale and the pulp of roasted apples, with sugar and spice.

Limburger Cheese.—A kind of cheese made at Herve, near Limburg, in Belgium. It is usually eaten in a state of putrefaction.

Limburger cheese, when made in summer, should be used before January 1st; but September and October cheese will keep all winter. Keep in a cool cellar; turn the boxes over every two or three weeks. It is better to wrap in parchment paper, as the foil is apt to turn the cheese black in two or three weeks' time. If the cheese is inclined to get too soft put sticks between the boxes to keep them from heating. When exposed for sale it should be kept under a glass cover.

Lime. — F. *Chaux;* Ger. *Kalk;* It. *Calcina;* Rus. *Iswest;* Sp. *Cal;* W. *Calch.*

Found in most parts of the world. The purest is obtained from limestone, marble, and chalk. None of these are really lime, but are easily converted into it by placing them in kilns or furnaces made for the purpose, and keeping them for some time in a white heat—the process being known as the *burning of lime;* the result is a mass of oxide of lime, which on being moistened falls to powder, giving out great heat. This

caustic and destructive property has given it the name of "quick" lime.

Lime has been used for making mortar from the earliest antiquity, but its use as a manure is entirely a European practice. It is usually applied to heavy loam soil, with the result of increased fertility, its beneficial effects apparently depending on its power in dissolving the potassium silicate and liberating the potash, which latter is of great value when taken up by the roots of plants.

Lime Cream.—An inseparable preparation is made by shaking:—Almond oil, 3lbs., with Liquor Potassæ 2 fluid ounces, in a clean, dry bottle, then gradually adding in small quantities at a time, water 8 to 12 fl. ozs., according to consistence required, and shaking after each addition. Finally add fresh Essence of Lemon ½ fl. oz., and, after again shaking, it will be complete.

Lime Wash.— See *Whiting and Whitewashing*.

Lime Water.—A solution of lime. Take a piece of unslaked lime the size of a hen's egg, put it into one gallon of cold water, stir this, and let it settle for twenty-four hours, remove the scum and bottle the liquid. With milk this forms an excellent diet in febrile affections or acidity of the stomach; or agitate an ounce of pure caustic lime in a pint bottle nearly full of water, and, after the lime has subsided, decant the clear liquid. Keep in well-stoppered bottles. Dose: One tablespoonful in a teacup of new milk.

Lime water is an article extremely likely to undergo chemical changes, and every time it is exposed to the air, or the stopper removed from the bottle, carbonic acid is admitted, and the change goes on; hence, although there is nothing to be gained by selling it under the B.P. strength, chemists and others are occasionally being fined for selling deficient lime water. It should contain half a grain of lime in every fluid ounce.

Limes or **Lime-fruit.** — F. *Limes;* G. *Leimen;* Port and Sp. *Limas.*—(See also *Pickled Limes.*)—The fruit of the citrus lime tree (*Citrus Limetta*), a species closely related to the lemon and orange, of which, like apple trees, there are several varieties. Their flavour is generally better liked than that of lemons; they are more juicy, and their acidity more acrid. In fact, limes are the more keenly acid of all fruits, but somewhat flat and bitter.

The lime-fruit produced in the West Indies, Florida, and in Southern Europe is of globular shape, or roundish oval, much smaller than a lemon, has a thinner rind, and its colour when the fruit arrives at a perfect state of maturity is a fine bright yellow, with a protuberance at the tip, like a nipple, and the pulp is very bitter.

The *Limetta lime* of India is a sweet variety. *Ogeechee limes* are of Floridan growth, rather larger than the others, and are very popular in the Southern States of America, in the form of a conserve. *Bergamotte limes* are another variety cultivated in the Mediterranean region, and are often, but erroneously, called "shaddocks."

Limes are classed by several botanists as hybrids, between lemons and oranges, and the fruit is used in flavouring punch and confectionery.

The export trade in green limes is very small, and confined to the English market. Such fruit is picked, wrapped in papers, packed, and shipped in crates like lemons, but does not keep so well. Sometimes the riper limes are exported in casks with brine.

The Greeks have a method of removing the pulp and core, and afterwards exporting the "shells," or hollow rinds, in casks with brine. They also often preserve the "shells" dry, and covered with a thin coating of sugar.

In Montserrat, Dominica, and other of the Leeward Islands the trees are raised from seed in nurseries, and transplanted when 10 or 18 inches high to the orchard, where they are planted in rows about 15 feet apart, or 150 to 200 to an acre, light, rich sandy loam being best suited to their growth. The flowers are small, white, and very fragrant. The trees bear fruit in three or four years after transplanting, and

continue bearing for about twenty years, but they are very easily damaged by frost. An average yield is 70 barrels of fruit per acre while in full bearing.

A barrel of fruit yields 6 to 8 gallons of juice, and a gallon of this will produce 12 to 15 oz. of citric acid.

A considerable quantity of limes are raised in Dominica. The lovely Roseau Valley in that island produces the best limes in the world, the luxuriant growth being attributed to the rich volcanic nature of the soil. The trees attain the size of apple or pear trees, and produce more limes to the acre than anywhere else in the world, but the orchards are smaller.

Antigua and St. Christopher only produce enough for home consumption, but in Montserrat the lime industry is very extensive, and carried on in a more systematic manner than in any other island of that group.

The fruit begins to ripen in June, when the harvest commences, and reaches its height in August.

Although lime-fruit orchards were first planted in Montserrat in 1852, limes were almost unknown fruits outside the fashionable world until about 1890, but they have now become an ordinary commodity.

For the last few years the average annual exports from Montserrat have been—*Raw lime juice*, 800 puncheons (120 gals. each); *concentrated lime juice*, 200 casks (54 gals. each); green limes, 1,000 crates or boxes; pickled limes, 300 barrels; and essential oil of limes, 2,500lbs.

Lime-Juice.—*Raw Lime-Juice* is simply the juice in its crude state, as obtained either by grinding the freshly-picked ripe and sound limes (*Citrus limetta*) in a cone mill, or squeezing them in a simple apparatus made for the purpose, or, better still, crushing them in old sugar-cane mills suitably set with rollers. It is afterwards strained and filtered, and put into air-tight casks immediately to prevent decomposition, and is then fit for shipment. This crude juice may be purchased in bulk on the London market at about 10d. per gallon, and is purchased by bottlers of cordials and other lime-juice beverages.

As an antiscorbutic it resembles lemon juice; but its acidity is more pronounced, and it is considered a more effective purifier of the blood.

The value of lime juice entirely depends on the amount of citric acid it contains. If of good quality, 100 grains will neutralise 70 to 76 grains of pure crystallised carbonate of soda.

It always forms part in the stores for ships going long voyages, especially to Arctic regions. Before the antiscorbutic qualities of lime juice were known, sea-scurvy was the dread of mariners; but since lime or lemon juice has been adequately supplied to crews of ships sea-scurvy has almost disappeared from the navy.

Concentrated Lime Juice is produced by placing the clarified juice in a copper battery, and then boiling on a slow fire (same way as sugar), taking care not to scorch it, as that destroys the acid. It is also sometimes prepared from the juice of the inferior qualities of limes, whether ripe or partly rotten, large or small, and concentrated, as already said, by boiling the juice in open pans until reduced to one-eighth or one-tenth its volume, and a density of 60° Twaddell or 52° Beaumé. It is then a black viscid fluid, and contains 10 to 100 oz. citric acid per gallon. Most of this concentrated juice comes from Sicily in casks of 130 gallons for citric-acid making. It is there obtained as a by-product in the manufacture of essential oils from the rinds of the fruit.

Some 50,000 gallons of lime juice are imported yearly from Jamaica in casks of 30 to 50 gallons; but Montserrat has lately become the chief centre of production, and it is there carried on in a more systematic manner than in any of the Leeward Islands. There is also a considerable quantity made in Dominica.

No iron vessels should be used for lime juice, as the iron turns the acid black and spoils the flavour.

For prices, etc., apply to Kimpton

Brothers, 36 and 37 Mincing Lane, London, E.C.; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Lime-Juice Cordials.—Preparations usually made from lime juice, sugar, and water, and flavoured with lemon peel or orange flowers—say sugar (or glucose), 4 oz.; syrup, 16 oz.; crude lime juice, 16 oz.; water, 28 oz.; and coloured with a little liquid saffron. It should be well filtered till fairly clear.

Lime and lemon juices being so liable to ferment, a small quantity of salicylic acid is necessary to check the fermentation; about an ounce of the acid to 20 gallons of the cordial is sufficient.

Some say this infringes the Food and Drug Act. It is certain that lime-juice and lime-juice cordials are often falsified with lemon juice and the Merchandise Marks Act violated.

Apply to Charles Cocks & Co., Reading, Berks.

Limes. — See *Lime Fruit* and *Pickled Limes.*

Limes, Essential Oil of.—There are two kinds of essential oil of limes—the hand-made, which is the most valuable; and the oil procured by distillation. The hand-made oil commands a much higher price, because its perfume is not affected by the heat necessary in distillation. Between 2,000 and 3,000 lbs. are exported yearly from Montserrat. The common method of extracting it there consists in the use of a shallow concave metal plate, shaped like a saucer, in which are studded a number of blunt copper spikes, and from the centre of which there is a tube which serves as a handle, and the lime is gently and quickly rolled over the blunt copper spikes until the oil escapes from the rind and runs into the tube.

When the tube is full, the oil is poured into bottles, which when full are allowed to stand until the water and other impurities settle; the oil is then carefully drawn off and filtered as it is run into tinned copper vessels ready for export. Only the finest limes are used, and afterwards they are ground up for the manufacture of lime juice.

Most of the oil exported from Dominica is distilled from raw lime juice as the latter leaves the mill. Oil of limes is chiefly employed in scenting soaps, and in the manufacture of common essences and perfumes.

Lime-seed Oil. — The oil of the lime-tree seed is distinguished by a beautiful clear colour and fine taste, has not a trace of bitterness or aromatic flavour, and may be justly compared to the finest olive oil. It is surprising this oil is not more utilised. The seeds possess 58 per cent. of oil, can be pressed in all sorts of ways, and its production can thus be scarcely surpassed by any other seed. The lime-tree produces the same enormous quantity of seed almost every year, which falls to the ground in autumn, and it is very easy to collect large quantities regularly.

The oil never goes rancid, and can be left exposed in open vessels without the slightest change in taste or preservation. Being a non-drying oil, it has not the least tendency to combine with oxygen. It is therefore valuable not only as a food oil, but also for industrial purposes. It does not freeze at any degree of cold known in England, and is not changed at even 21° Centigrade.

Limerick Twist. — A kind of tobacco popular with those persons whose means will not permit them to buy better, or whose taste is not particularly acute. There is undoubtedly much good tobacco used in its manufacture, but it often covers a mass of abominations, all sorts of leaf and fag ends of the tobacco factory.

A great deal of it is now made in England and Scotland, as well as in Ireland. (See *Tobaccos.*)

Limetta Limes.—See *Lime Fruit.*

Lincolnshire Cheese.—A small soft cheese, very rich, made of new milk and cream, in pieces of 2 inches thick; will keep one to three months only.

Linden-seed Oil.—F. *Huile de Tilleul.* This is a new table oil coming into competition with olive oil. The linden-tree (*Tilia Europæa*) flourishes

throughout Europe and North America, and is often cultivated for the sake of shade. Its leaves are plain and alternate, and its flowers grow in bunches. Each flower has a corolla with 5 petals and a large number of stamens. It is a regular and prolific bearer of seed, and the percentage of oil in the seed is given at 58. It has a peculiarly fine flavour—free from all bitter and aromatic taste—and has the general appearance of olive oil. The seeds will also produce chocolate analogous to that made from cocoa nibs.

Linden-seed oil never turns rancid, has no tendency to oxygenate, and does not evaporate. It will also stand great cold, say three degrees below zero, without either freezing or even changing, and is often used in preparing tonic infusions.

Ling. — (See also *Stock Fish.*)—A valuable fish of the cod tribe, the *Lota Molva.* Besides these consumed fresh, considerable quantities are cured for export.

The name is also applied to hake when cured.

Ling Nuts. —See *Water or Trapa Nuts.*

Links. —See *Torches.*

Linseed, or **Flax Seed.** — Da. *Horfrö;* Du. *Lynzaad;* F. *Graine de Lin;* G. *Leimsaat;* It. *Linseme;* Port. *Linhaca;* Rus. *Semja Leujanoe;* Sp. *Linaza;* Sw. *Linfrö;* W. *Llinhad.*

From the Anglo-Saxon words *lin* (flax) and *sæd* (seed).

The dried, ripe, and shiny seeds of lint or flax plant (*Linum usitatissimum*), which are odourless, rich in mucilage and oil, and are considered the most valuable artificial feeding stuff for cattle.

Linseed is mostly imported into this country from abroad; 50 per cent. of it comes from India, 41 per cent. from Russia; Argentina, Holland, and Turkey send the rest. Its cultivation is, however, being largely extended in Argentina, and, as it is better cleaned and cheaper than Indian, it is being preferred by several crushers. In size and weight the seeds range as follow:—Argentine, Bombay, Turkish, Canadian, Dutch, Russian, English, the last being the smallest. Sicilian has an excess of husk.

Flax, being considered to be a great exhauster of the soil, is not much cultivated in England; but in Ireland it forms a more important crop, yet seems to be on the decline even there. From this seed we obtain several valuable products, but no starch. The bright brown Dutch seed is the most profitable for cultivation; its growth is rapid, and the crop more abundant.

Indian and Russian are generally bought for the oil mills, these being the richest in oil, although the former often contains much black, stony, and earthy matter. In Berar, a province of Central India, there are over 300,000 acres devoted to the growth of this seed, chiefly in the districts of Nagpur, Raipur, and Bilaspur. The seed is sown three weeks earlier than wheat, and does well where the soil is not deep enough for the wheat.

The *red* seed usually comes into the market mixed with rape and other seeds, which naturally lessens its value. A quarter of English linseed weighs about 424lbs., Black Sea 424lbs., Bombay 416lbs., and Calcutta 410lbs., and will yield by pressure about 120lbs. of oil and 280lbs. of oil-cake.

Special Firms.—Hedley, Gamble, & Crosfield (Cleaners), Circus Street, Liverpool; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Linseed Cake. — F. *Tourteaux de Lins.* (See also *Oil Cake* and *Cotton Seed Oil Cake.*)

Linseed cake is an oil cake, but oil cakes are not always linseed cakes.

This popular cattle food is generally made from the mass of crushed seed coats, husks, or refuse, and mucilage remaining after a portion, varying from 15 to 30 per cent., of the linseed oil has been pressed out of the seed. It is usually made up into thin flat cakes about 24 inches long, 6 to 9 inches wide, and 1 inch thick.

Its value depends mostly on the

amount of oil or fat left in, and this varies from 10 to 20 per cent., according to the amount of pressure used. This percentage is very important, because the fat is not only valuable in itself, but an aid to the animal in digesting the other ingredients. It may be roughly estimated by crushing a pound of the cake into a gallon of boiling water, and noticing whether the jelly which afterwards forms is very thick and rich, or thin and poor. It is sometimes adulterated with colza, various kinds of mustard seed, hemp seed, poppy, *ricinus arachis*, etc., but a decoction of genuine linseed, when cold, is not made blue by solution of iodine.

Linseed Meal. — This yellowish-grey powder consists of linseed reduced to powder and not deprived of its oil. There are three or four sorts in the market. The best consists simply of genuine bruised linseed. A cheap sort is made from seed after the greater part of the oil has been extracted. Another is made by grinding oil-cake.

Buyers who want the genuine should be careful to ask for "crushed linseed," the latest official name for it. Commercial samples vary much in the quantity of oil they contain. Some range as high as 50 per cent., others as low as 20 per cent. of oil. None should have less than 30 per cent.; should not yield more than 6 per cent. of ash; should be free from unpleasant or rancid odour. A decoction when cold should not become blue on the addition of solution of iodine (absence of starch); the meal should not give off a pungent odour when treated with warm water (absence of cruciferous seeds). If kept too long in stock it may easily fall short of these requirements.

Although grocers have often been fined for selling linseed adulterated with starch or meal sweepings, and should be careful what they buy, it was decided in the Queen's Bench Division, November, 1896, that linseed meal was *not* a drug. Mr. Justice O'Brien held that there were several things capable of being used as medicines which were not drugs. A drug should mean a thing the primary object of which was medicinal. Mr. Justice Johnson concurred; and Mr. Justice Gibson agreed that the essential of a drug was that it was used as a medicine, and that "where the purchaser did not indicate what he required a prosecution could not succeed." There is no starch in genuine linseed, but cellulose, and that cannot be converted into starch. Linseed meal is often used for poultices, also mixed with milk or water for calf or cattle food. Its value may be pretty closely tested in same way as linseed cake.

Special Firms.—Hedley, Gamble, & Crosfield, Circus Street, Liverpool; Morris & Jones, 13 to 19 Sir Thomas Street, Liverpool.

Linseed Oil. — Da. *Lünolie;* Du. *Lynöli;* F. *Huile de Lin;* G. *Leinoel;* It. *Olio di Lino;* Pol. *Oley Luiany;* Port. *Olio de Linhaca;* Rus. *Lejanoe Masslo;* Sp. *Aceite de Linaza.*

A peculiar drying oil expressed from linseed, or flax-seed. The oil varies in colour from light amber to dark yellow, but when purified it is quite colourless. It has a rather sickly smell and taste. In the preparation of the oil the ripe seeds are first crushed or ground, and then subjected to hot or cold pressure. Oil expressed from unripe seed is watery and unfit for use, and the seed should always be kept three to four months before crushing, when a more abundant yield of oil may be obtained.

By far the best oil is the "cold drawn," and will not turn rancid so soon, but this cold pressure only yields 15 to 18 per cent. It is very unctuous, and unpleasant to the taste and smell, and by exposure to the air and light it becomes dry. If the seed be treated with about 200° of steam heat, 30 to 40 per cent. of oil, known as "raw" or "ordinary," may be expressed.

This "hot drawn" oil is of a yellowish red, or deep wine colour, and is more nauseous than the cold drawn. Boiled linseed oil, or "boiled oil," as it is frequently called, dries in the air much quicker than does the unboiled oil. It is usually prepared by boiling the raw

oil with either litharge, white lead, or sulphate of zinc, and is therefore preferable for mixing with paints; but there is still much to be learned with regard to the chemical processes involved in the so-called drying of linseed oil. Cotton-seed oil, though not strictly a "drying oil" of itself, will act as such when mixed with linseed oil, but not so well. Linseed oil is mostly used in preparing varnishes, paints, printer's ink, soft soap, and floorcloths, etc. Mixed with lime-water it is often usefully applied to burns and scalds.

The annual production of linseed oil in the U.K. approximates 28 million gallons. The best test of quality is the smell and taste.

The chief adulterants are cotton-seed oil, cod oil, resin oil, and linoleic acid.

Liptau Cheese.—See *Bringen*.
